## **About This Book**

This book provides system programmers with complete detailed information about kernel services, device driver operations, and file system operations for the AIX® operating system. Kernel services, device driver operations, and file system operations are listed alphabetically by topic. This book is intended for system programmers wishing to extend the kernel, and to use the book effectively, you should be familiar with operating system concepts and kernel programming. This book is also available on the documentation CD that is shipped with the operating system.

This book is part of the six-volume technical reference set, that provides information on system calls, kernel extension calls, and subroutines in the following volumes:

- AIX Version 7.1 Technical Reference: Base Operating System and Extensions, Volume 1 and AIX
   Version 7.1 Technical Reference: Base Operating System and Extensions, Volume 2 provide information
   on system calls, subroutines, functions, macros, and statements associated with base operating system
   runtime services.
- AIX Version 7.1 Technical Reference: Communications, Volume 1 and AIX Version 7.1 Technical Reference: Communications, Volume 2 provide information on entry points, functions, system calls, subroutines, and operations related to communications services.
- AIX Version 7.1 Technical Reference: Kernel and Subsystems, Volume 1 and AIX Version 7.1 Technical Reference: Kernel and Subsystems, Volume 2 provide information about kernel services, device driver operations, file system operations, subroutines, the configuration subsystem, the communications subsystem, the low function terminal (LFT) subsystem, the logical volume subsystem, the M-audio capture and playback adapter subsystem, the printer subsystem, the SCSI subsystem, and the serial DASD subsystem.

# Highlighting

The following highlighting conventions are used in this book:

Bold

Italics

Monospace

Identifies commands, subroutines, keywords, files, structures, directories, and other items whose names are predefined by the system. Also identifies graphical objects such as buttons, labels, and icons that the user selects. Identifies parameters whose actual names or values are to be supplied by the user.

Identifies examples of specific data values, examples of text similar to what you might see displayed, examples of portions of program code similar to what you might write as a programmer, messages from the system, or information you should actually type.

# Case-Sensitivity in AIX®

Everything in the AIX® operating system is case-sensitive, which means that it distinguishes between uppercase and lowercase letters. For example, you can use the **Is** command to list files. If you type LS, the system responds that the command is "not found." Likewise, **FILEA**, **FiLea**, and **filea** are three distinct file names, even if they reside in the same directory. To avoid causing undesirable actions to be performed, always ensure that you use the correct case.

#### **ISO 9000**

ISO 9000 registered quality systems were used in the development and manufacturing of this product.

© Copyright IBM Corp. 2010

# 32-Bit and 64-Bit Support for the Single UNIX® Specification

Beginning with Version 5.2, the operating system is designed to support The Open Group's Single UNIX Specification Version 3 (UNIX 03) for portability of UNIX-based operating systems. Many new interfaces, and some current ones, have been added or enhanced to meet this specification, making Version 5.2 even more open and portable for applications, while remaining compatible with previous releases of AIX®. To determine the proper way to develop a UNIX® 03-portable application, you may need to refer to The Open Group's UNIX® 03 specification, which can be accessed online or downloaded from http://www.unix.org/.

## **Related Publications**

The following books contain information about or related to application programming interfaces:

- AIX Version 7.1 General Programming Concepts: Writing and Debugging Programs
- AIX Version 7.1 Communications Programming Concepts
- AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts

# **Chapter 1. Kernel Services**

# \_pag\_getid System Call

## **Purpose**

Invokes the kcred getpagid kernel service and returns the PAG identifier for that PAG name.

# **Syntax**

```
int __pag_getid (name)
char *name;
```

# **Description**

Given a PAG type name, the **\_\_pag\_getid** invokes the **kcred\_getpagid** kernel service and returns the PAG identifier for that PAG name.

#### **Parameters**

name

A **char** \* value which references a NULL-terminated string of not more than PAG NAME LENGTH MAX characters.

## **Return Values**

If successful, a value greater than or equal to 0 is returned and represents the PAG type. This value may be used in subsequent calls to other PAG system calls that require a *type* parameter on input. If unsuccessful, -1 is returned and the **errno** global variable is set to a value reflecting the cause of the error.

#### **Error Codes**

**ENOENT** The *name* parameter doesn't refer to an existing PAG type.

**ENAMETOOLONG** The *name* parameter refers to a string that is longer than PAG\_NAME\_LENGTH\_MAX.

## **Related Information**

```

# \_\_pag\_getname System Call

# **Purpose**

Retrieves the name of a PAG type.

# **Syntax**

```
int __pag_getname (type, buf, size)
int type;
char *buf;
int size;
```

# **Description**

The <u>pag\_getname</u> system call retrieves the name of a PAG type given its integer value by invoking the **kcred\_getpagname** kernel service with the given parameters.

© Copyright IBM Corp. 2010

## **Parameters**

type A numerical PAG identifier.

buf A char \* value that points to an array at least PAG\_NAME\_LENGTH\_MAX+1 bytes in length.

size An **int** value that gives the size of *buf* in bytes.

#### **Return Values**

If successful, 0 is returned and the *buf* parameter contains the PAG name associated with the *type* parameter. If unsuccessful, -1 is returned and the **errno** global variable is set to a value reflecting the cause of the error.

## **Error Codes**

**EINVAL** The value of the *type* parameter is less than 0 or greater than the maximum PAG identifier.

**ENOENT** There is no PAG associated with the *type* parameter.

**ENOSPC** The value of the *size* parameter is insufficient to hold the PAG name and its terminating NULL

character.

## **Related Information**

# \_pag\_getvalue System Call

## **Purpose**

Invokes the kcred\_getpag kernel service and returns the PAG value.

# **Syntax**

int \_\_pag\_getvalue (type)
int type;

# **Description**

Given a PAG type, the **\_\_pag\_getvalue** system call invokes the **kcred\_getpag** kernel service and returns the PAG value for the value of the *type* parameter.

#### **Parameters**

type An **int** value indicating the desired PAG.

#### **Return Values**

If successful, the value of the PAG (or 0 when there is no value for that PAG type) is returned. If unsuccessful, -1 is returned and the **errno** global variable is set to a value reflecting the cause of the error.

#### **Error Codes**

**EINVAL** The *type* parameter is less than 0 or greater than the maximum PAG type value.

**ENOENT** The *type* parameter doesn't reference and existing PAG type.

Note: It is not an error for a defined PAG to not have a value in the current process' credentials.

## **Related Information**

"\_\_pag\_getid System Call" on page 1, "\_\_pag\_getname System Call" on page 1, "\_\_pag\_setname System Call," "\_\_pag\_setvalue System Call," "kcred\_getpagid Kernel Service" on page 248, "kcred\_getpagname Kernel Service" on page 249, and "kcred\_setpagname Kernel Service" on page 254.

## \_\_pag\_setname System Call

## **Purpose**

Invokes the kcred\_setpagname kernel service and returns the PAG type identifier.

## **Syntax**

```
int __pag_setname (name, flags)
char *name;
int flags;
```

# **Description**

The \_\_pag\_setname system call invokes the kcred\_setpagname kernel service to register the name of a PAG and returns the PAG type identifier. The value of the *func* parameter to kcred\_setpagname will be NULL. The other parameters to this system call are the same as with the underlying kernel service. This system call requires the SYS\_CONFIG privilege.

## **Parameters**

name A char \* value giving the symbolic name of the requested PAG. flags Either PAG\_UNIQUEVALUE or PAG\_MULTIVALUED 1 .

## **Return Values**

A return value greater than or equal to 0 is the PAG type associated with the *name* parameter. This value may be used with other PAG-related system calls which require a numerical PAG identifier. If unsuccessful, -1 is returned and the **errno** global variable is set to indicate the cause of the error.

## **Error Codes**

**ENOSPC** The PAG name table is full.

**EEXIST** The named PAG type already exists in the table, and the *flags* and *func* parameters do not match

their previous values.

**EPERM** The calling process does not have the SYS\_CONFIG privilege.

#### **Related Information**

# \_pag\_setvalue System Call

# **Purpose**

Invokes the kcred setpag kernel service and sets the value of PAG type to pag.

# **Syntax**

```
int __pag_setvalue (type, pag)
int type;
int pag;
```

## **Description**

Given a PAG type and value, the **\_\_pag\_setvalue** system call invokes the **kcred\_setpag** kernel service and sets the value of PAG type to *pag*. This system call requires the SET\_PROC\_DAC privilege.

## **Parameters**

type An **int** value indicating the desired PAG. pag An **int** value containing the new PAG value.

## **Return Values**

If successful, 0 is returned. If unsuccessful, -1 is returned and the **errno** global variable is set to a value reflecting the cause of the error.

#### **Error Codes**

**ENOENT** The *type* parameter doesn't reference an existing PAG type.

**EINVAL** The value of *pag* is -1.

**EPERM** The calling process lacks the appropriate privilege.

# acct\_add\_LL or acct\_zero\_LL Kernel Service

# **Purpose**

Increments counters for advanced accounting.

# **Syntax**

```
unsigned long long acct_add_LL(ptr, incr)
unsigned long long *ptr;
unsigned int incr;
unsigned long long acct_zero_LL(ptr)
unsigned long long *ptr;
```

## **Parameters**

ptr Address of statistic to be incremented.

incr Increment to be applied.

# **Description**

These kernel services are special atomic increment and clear services that are designed to allow machine-independent updating of unsigned long long values. The increment service only performs an increment if advanced accounting is enabled.

The acct\_add\_LL kernel service adds the value associated with the incr parameter to the 64-bit counter at the address designated by the ptr parameter. The acct\_zero\_LL kernel service atomically zeroes the 64-bit counter.

Both routines return the previous value of the 64-bit counter. This way, the acct\_zero\_LL kernel service can be used to atomically get the most recent value and set the counter to NULL. Because only delta statistics are reported each interval, this capability is required by interval accounting when the accounting record is being built for a report.

#### **Execution Environment**

These kernel services can be called from either the interrupt environment or the process environment.

## **Return Values**

These subroutines return the previous value of the location designated by the ptr parameter.

## **Related Information**

"acct interval register or acct interval unregister Kernel Service" on page 7, "acct put Kernel Service" on page 8

## acct get projid Kernel Service

# **Purpose**

Gets the project identifier for the current process.

# **Syntax**

projid\_t acct\_get\_projid(void)

# Description

The acct get projid kernel service returns the project identifier for the current process.

#### **Execution Environment**

The acct\_get\_projid kernel service can be called from the process environment only.

## **Return Values**

The acct\_get\_projid kernel service returns the current project identifier.

## **Related Information**

"acct\_put Kernel Service" on page 8

# acct get usage Kernel Service

# **Purpose**

Allows kernel extensions to measure the resource utilization of transactions.

## **Syntax**

```
#include <sys/types.h>
#include <sys/aacct.h>
unsigned long long acct get usage(usage)
struct tusage *usage;
```

#### **Parameters**

usage Resource utilization structure.

## **Description**

This routine is used to measure the resource utilization of a client transaction, so that the cost of the transaction can be included within the accounting record that identifies the client transaction. This accounting record is then used for chargeback purposes.

The acct get usage kernel service is designed to be called twice: once at the start of a transaction and a second time at the end of a transaction. Each time that the routine is called, it returns the resource utilization for the calling thread from creation using the *usage* parameter. Therefore, this routine can be called multiple times to determine the resource utilization of a code fragment by subtracting start and end values.

The following macros are provided for manipulating the usage parameter:

#### TUSAGE ZERO(TU)

Initializes the tusage structure

#### TUSAGE\_ADD(TU1, TU2)

Adds **tusage** structures (T1 = T1 + T2)

#### TUSAGE SUB(TU1, TU2)

Subtracts **tusage** structures (T1 = T1 - T2)

The usage parameter provides thread-specific information, so the caller must ensure that this routine is called from the same thread context when measuring the utilization of a transaction. The return value identifies the calling thread context.

The acct get usage kernel service returns a token that identifies the calling context. This token can be logically compared with other tokens returned by this routine to ensure that start and stop invocations were made from the same thread. The scope of the token depends on the context of the calling program. If this routine is called under a pthread, then it returns a token representing the currently executing pthread. Otherwise, the acct\_get\_usage kernel service returns a token representing the currently executing kernel thread. In the former case, the token has process-wide scope; in the latter case, the token has system-wide scope.

## **Execution Environment**

The acct\_get\_usage kernel service can only be called from the process environment.

#### Return Values

Upon successful completion, the acct\_get\_usage kernel service returns a token that identifies the calling thread context.

## **Related Information**

"acct\_add\_LL or acct\_zero\_LL Kernel Service" on page 4, "acct\_get\_projid Kernel Service" on page 5, "acct\_interval\_register or acct\_interval\_unregister Kernel Service," "acct\_put Kernel Service" on page 8

## acct interval register or acct interval unregister Kernel Service

## **Purpose**

Registers or unregisters an advanced accounting handler.

## **Syntax**

```
#include <sys/aacct.h>
int acct_interval_register(trid, cmds, handler, arg, reg token, reg name)
int cmds;
int (*handler)(int trid, int cmds, void *arg);
void *arg;
unsigned long *reg token;
char *reg name;
int acct interval unregister(reg token)
unsigned long reg_token;
```

#### **Parameters**

trid Transaction identifier

cmds Invocations supported by the advanced accounting handler

handler Function descriptor for the handler

Identifies the instance of the kernel extension arg

Token that is returned to caller naming the instance of the registration reg\_token

Identifies the transaction using a string reg\_name

# **Description**

The acct\_interval\_register kernel service registers accounting records that are produced by the kernel extension with the advanced accounting subsystem. These accounting records are named through accounting transaction identifiers, which are provided by the caller. Transaction identifiers are persistent in nature, because they are used by report and analysis utilities to interpret transaction-specific accounting data. The transaction identifier is implicitly mapped to a template.

Transaction identifiers (and associated templates) used by AIX® are defined in the sys/aacct.h file. Identifiers in the range of 0-127 are reserved for AIX<sup>®</sup>. Vendors can choose any value in the range 128 – 256 for their accounting records. If two vendors choose the same value, report and analysis programs must reference other fields in the accounting record header to uniquely identify the source of the transaction; that way, they can apply the appropriate template. The subproject field (which specifies the command name of the logger) and length field can be used to identify the source of the transaction. Collisions are very unlikely to occur. The transaction identifier and the transaction name, which is provided by the reg name field, are presented to the system administrator. Vendors should choose representative names for their transactions. The maximum length of a transaction name is 15 bytes.

Administrators can enable and disable transactions, and thereby drive callouts to the kernel extension. A function descriptor for the advanced accounting handler is provided through the handler parameter. The interface of this handler is:

```
int handler(int trid, int cmd, void *arg);
```

The *trid* parameter is the transaction being acted on. The *cmd* parameter describes the action. The *arg* parameter is a value that was specified at registration for this particular instance of the handler. The *arg* parameter is specific to the kernel extension.

The following *cmd* values are supported:

ACCT\_CMD\_ENABLE The transaction is being enabled; start collecting.

ACCT\_CMD\_DISABLE The transaction is being disabled; stop collecting.

ACCT\_CMD\_INTERVAL The system interval has expired; provide accounting data.

ACCT\_CMD\_FSWITCH The active accounting file has changed; provide meta data.

The handler is invoked in the process environment from a dedicated kernel-only thread that is part of the advanced accounting subsystem. The kernel extension registers for the callouts that should be made by logically ORing *cmd* values. The *cmds* parameter to the **acct\_interval\_register** kernel service is provided for this purpose.

When a transaction is enabled, the kernel extension should allocate accounting structures and start collecting statistics. When a transaction is disabled, the kernel extension should quit collecting statistics and free accounting structures. If a transaction is not enabled, the kernel subsystem should not collect statistics for the transaction. The kernel extension relies on the callout mechanism to provide notification when a transaction is enabled. This way, accounting records that are not required for the report are not collected and the accounting overhead is minimized.

If the kernel extension registers for interval accounting, the extension is called when the system interval expires. The handler should record its data using the **acct\_put** kernel service and should reset its counters so that only delta statistics are produced in the next interval. The **acct\_zero\_LL** and **acct\_add\_LL** kernel services are provided so that statistics can be reported and zeroed atomically. When the system interval is disabled, the system automatically generates an interval callout to collect the last round of statistics.

The file switch callout is provided, so that subsystems can record accounting data in each accounting file. Most subsystems are not expected to use this option.

## **Execution Environment**

The acct\_interval\_register kernel service can be called from the process environment only.

The **acct\_interval\_unregister** kernel service can be called from either the interrupt environment or the process environment.

#### **Return Values**

Upon successful completion, 0 is returned. If unsuccessful, errno is set to a value that explains the error.

#### Related Information

"acct\_add\_LL or acct\_zero\_LL Kernel Service" on page 4, "acct\_put Kernel Service"

# acct\_put Kernel Service

# **Purpose**

Writes an accounting record.

## **Syntax**

```
#include <sys/aacct.h>
void acct put(trid, flags, projid, usage, trdata, tr len);
int trid;
int flags;
projid_t projid;
struct tusage *usage;
void *trdata;
int tr len;
```

#### **Parameters**

trid Transaction identifier.

flags Flags associated with the transaction or the production of the transaction. The following value is

defined:

ACCT\_PUT\_DIRECT

Overrides aggregate transaction

projid Project identifier, associated with the transaction, that identifies the billable entity. The following

values are defined:

PROJID\_SYSTEM

This identifier is typically associated with system overhead and is often used for shared devices, such as disks and network adapters.

PROJID UNKNOWN

This identifier is used when the billable entity is unknown to the caller. In this case, the system calculates the project identifier using the project assignment policy specified by the system administrator.

project identifier

If the project identifier is known, it should be specified.

Identifies the resource usage values associated with the transaction. usage

Transaction-specific information. trdata

Size of the transaction-specific data in bytes. tr\_len

# **Description**

The acct put kernel service provides accounting data to the advanced accounting subsystem. This service builds the accounting record header from its parameters and values associated with the calling context. The transaction-specific data specified by the caller is copied after the header. This data is internally buffered so that it can be written efficiently to the accounting data file some time later.

The trid parameter identifies the type of transaction that is being provided and implicitly identifies the format of the transaction-specific data. This identifier is included within the accounting header and is used by report and analysis commands to infer the right template that can interpret transaction-specific data. Vendors are encouraged to document their transaction identifiers and record templates so that report and analysis tools can be produced to interpret this data.

Accounting transaction identifiers are defined in the following range:

AIX® accounting transaction identifiers 0 - 127128-255 Vendor accounting transaction identifiers

The ACCT\_PUT\_DIRECT flag is provided as an override to the aggregation of accounting records, which is an optional feature of the advanced accounting subsystem. By default, the system does not aggregate accounting data. Aggregation is designed to reduce the volume of data that is written to the accounting file. It is transparent to applications and middleware. When aggregation is enabled, the system throws out the transaction-specific data and produces statistics about the occurrence of the transaction and the aggregate resource utilization. The data is produced along project boundaries, so the ability to perform chargeback is not lost, although the data that is produced is different. Statistical information about the transaction is captured in the accounting file in lieu of the transaction.

Because aggregation might not be desirable in some cases, the ACCT PUT DIRECT flag is provided to override this feature. For example, because the significance of a transaction that describes the shared use of a disk is bound up in the transaction-specific data, the transaction cannot be effectively aggregated. The significance of the transaction is thrown out in the course of aggregation. In effect, the statistic has already been aggregated by the producer, so it should be written directly to the file instead of being aggregated again by the accounting subsystem.

The usage values pointed to by the usage parameter is calculated using the acct\_get\_usage kernel service. The usage parameter is optional. A value of NULL can be specified to signify no usage information. Aggregation uses this field to accumulate resource utilization. If this information is calculated for the transaction, it should be passed as a parameter to this routine, instead of just including it within the transaction-specific data section. The advanced accounting subsystem does not know the format of this section and cannot aggregate it. In such a case, this section would be thrown out when aggregation is enabled.

The trdata parameter contains the address of a buffer containing transaction-specific data, and the tr len parameter identifies the number of bytes in this buffer that should be copied to the accounting file. A maximum of 16 KB of data can be written.

## **Execution Environment**

The acct put kernel service can be started from either the process or interrupt environment. However, aggregation of the transaction is only supported when the acct put service is started from the process environment.

#### **Return Values**

The acct\_put kernel service does not return a value.

#### **Related Information**

The acctctl Command.

"acct\_add\_LL or acct\_zero\_LL Kernel Service" on page 4, "acct\_get\_projid Kernel Service" on page 5, "acct\_get\_usage Kernel Service" on page 5, "acct\_interval\_register or acct\_interval\_unregister Kernel Service" on page 7

# add domain af Kernel Service

# **Purpose**

Adds an address family to the Address Family domain switch table.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/domain.h> int add\_domain\_af ( domain) struct domain \*domain;

## **Parameter**

domain Specifies the domain of the address family.

## **Description**

The **add\_domain\_af** kernel service adds an address family domain to the Address Family domain switch table.

## **Execution Environment**

The add\_domain\_af kernel service can be called from either the process or interrupt environment.

## **Return Values**

Indicates that the address family was successfully added.
 Indicates that the address family was already added.

**EINVAL** Indicates that the address family number to be added is out of range.

## **Example**

To add an address family to the Address Family domain switch table, invoke the **add\_domain\_af** kernel service as follows:

add domain af(&inetdomain);

In this example, the family to be added is inetdomain.

## **Related Information**

The del\_domain\_af kernel service.

Network Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# add\_input\_type Kernel Service

# **Purpose**

Adds a new input type to the Network Input table.

# **Syntax**

#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>
#include <net/netisr.h>
int add\_input\_type (type, service\_level, isr, ifq, af)
u\_short type;
u\_short service\_level;
int (\* isr) ();
struct ifqueue \* ifq;
u\_short af;

## **Parameters**

Specifies which type of protocol a packet contains. A value of x'FFFF' indicates that this type

input type is a wildcard type and matches all input packets.

Determines the processing level at which the protocol input handler is called. If the service level

service\_level parameter is set to NET\_OFF\_LEVEL, the input handler specified by the isr parameter is called directly. Setting the service level parameter to NET\_KPROC schedules a network dispatcher. This dispatcher calls the subroutine identified by the isr parameter.

Identifies the routine that serves as the input handler for an input packet type. isr

Specifies an input gueue for holding input buffers. If this parameter has a non-null value, an ifq

input buffer (mbuf) is enqueued. The ifq parameter must be specified if the processing level specified by the service\_level parameter is NET\_KPROC. Specifying null for this parameter generates a call to the input handler specified by the isr parameter, as in the following: Specifies the address family of the calling protocol. The af parameter must be specified if the ifq parameter is not a null character. This parameter must be greater than or equal to 0

and less than **NETISR MAX**. Refer to **netisr.h** for the range of values of *af* that are already in use. Also, other kernel extensions that are not AIX® and that use network ISRs currently

running on the system can make use of additional values not mentioned in netisr.h.

(\*isr)(CommonPortion,Buffer);

In this example, CommonPortion points to the network common portion (the arpcom structure) of a network interface and Buffer is a pointer to a buffer (mbuf) containing an

input packet.

# **Description**

af

To enable the reception of packets, an address family calls the add\_input\_type kernel service to register a packet type in the Network Input table. Multiple packet types require multiple calls to AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts the add\_input\_type kernel service.

## **Execution Environment**

The add input type kernel service can be called from either the process or interrupt environment.

#### **Return Values**

Indicates that the type was successfully added.

**EEXIST** Indicates that the type was previously added to the Network Input table.

**ENOSPC** Indicates that no free slots are left in the table.

**EINVAL** Indicates that an error occurred in the input parameters.

# **Examples**

1. To register an Internet packet type (TYPE IP), invoke the add input type service as follows:

```
add input type(TYPE IP, NET KPROC, ipintr, &ipintrq, AF INET);
```

This packet is processed through the network kproc. The input handler is ipintr. The input queue is ipintrq.

2. To specify the input handler for ARP packets, invoke the add\_input\_type service as follows:

```
add input type(TYPE ARP, NET OFF LEVEL, arpinput, NULL, NULL);
```

Packets are not queued and the arpinput subroutine is called directly.

## **Related Information**

The **del input type** kernel service, **find input type** kernel service.

Network Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## add\_netisr Kernel Service

## **Purpose**

Adds a network software interrupt service to the Network Interrupt table.

# **Syntax**

#include <sys/types.h>
#include <sys/errno.h>
#include <net/netisr.h>
int add\_netisr ( soft\_intr\_level, service\_level, isr)
u\_short soft\_intr\_level;
u\_short service\_level;
int (\*isr) ();

## **Parameters**

soft intr\_level Specifies the software interrupt level to add. This parameter must be greater than or

equal to 0 and less than **NETISR\_MAX**. Refer to **netisr.h** for the range of values of *soft\_intr\_level* that are already in use. Also, other kernel extensions that are not AIX<sup>®</sup> and that use network ISRs currently running on the system can make use of additional

values not mentioned in netisr.h.

service\_level Specifies the processing level of the network software interrupt.

isr Specifies the interrupt service routine to add.

# **Description**

The **add\_netisr** kernel service adds the software-interrupt level specified by the *soft\_intr\_level* parameter to the Network Software Interrupt table.

The processing level of a network software interrupt is specified by the *service\_level* parameter. If the interrupt level specified by the *service\_level* parameter equals **NET\_KPROC**, a network interrupt scheduler calls the function specified by the *isr* parameter. If you set the *service\_level* parameter to **NET\_OFF\_LEVEL**, the **schednetisr** service calls the interrupt service routine directly.

## **Execution Environment**

The add netisr kernel service can be called from either the process or interrupt environment.

#### **Return Values**

Indicates that the interrupt service routine was successfully added.

**EEXIST** Indicates that the interrupt service routine was previously added to the table.

**EINVAL** Indicates that the value specified for the *soft\_intr\_level* parameter is out of range or at a service level that

is not valid.

#### **Related Information**

The del netisr kernel service.

Network Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## add\_netopt Macro

## **Purpose**

Adds a network option structure to the list of network options.

## **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <net/netopt.h> add\_netopt ( option\_name\_symbol, print\_format) option\_name\_symbol; char \*print format;

## **Parameters**

option\_name\_symbol Specifies the symbol name used to construct the netopt structure and default

names.

Specifies the string representing the print format for the network option. print\_format

## **Description**

The add\_netopt macro adds a network option to the linked list of network options. The no command can then be used to show or alter the variable's value.

The add netopt macro has no return values.

#### **Execution Environment**

The add netopt macro can be called from either the process or interrupt environment.

## **Related Information**

The **no** command.

The **del\_netopt** macro.

Network Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# as att64 Kernel Service

# **Purpose**

Allocates and maps a specified region in the current user address space.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/vmuser.h> #include <sys/adspace.h> unsigned long long as\_att64 (vmhandle, offset) vmhandle t vmhandle; int offset;

#### **Parameters**

vmhandle Describes the virtual memory object being made addressable in the address space.

offset Specifies the offset in the virtual memory object. The upper 4-bits of this offset are ignored.

# **Description**

The as\_att64 kernel service: Selects an unallocated region within the current user address space.

Allocates the region.

Maps the virtual memory object selected by the vmhandle parameter

with the access permission specified in the handle.

Constructs the address of the offset specified by the offset parameter

within the user-address space.

The as\_att64 kernel service assumes an address space model of fixed-size virtual memory objects.

This service will operate correctly for both 32-bit and 64-bit user address spaces. It will also work for kernel processes (*kprocs*).

**Note:** This service only operates on the current process's address space. It is not allowed to operate on another address space.

## **Execution Environment**

The as\_att64 kernel service can be called from the process environment only.

## **Return Values**

On successful completion, this service returns the base address plus the input offset (offset) into the allocated region.

**NULL** An error occurred and ernno indicates the cause:

**EINVAL** Address specified is out of range, or

**ENOMEM** Could not allocate due to insufficient resources.

#### **Related Information**

The as\_seth64 kernel service, as\_det64 kernel service, as\_geth64 kernel service, as\_getsrval64 kernel service, as\_puth64 kernel service.

# as\_det64 Kernel Service

# **Purpose**

Unmaps and deallocates a region in the current user address space that was mapped with the **as\_att64** kernel service.

# **Syntax**

#include <sys/errno.h> #include <sys/adspace.h> int as\_det64 (addr64) unsigned long long addr64;

## **Parameters**

addr64 Specifies an effective address within the region to be deallocated.

## **Description**

The **as\_det64** kernel service unmaps the virtual memory object from the region containing the specified effective address (specified by the **addr64** parameter).

The as det64 kernel service assumes an address space model of fixed-size virtual memory objects.

This service should not be used to deallocate a base kernel region, process text, process private or an unallocated region. An **EINVAL** return code will result.

This service will operate correctly for both 32-bit and 64-bit user address spaces. It will also work for kernel processes (*kprocs*).

**Note:** This service only operates on the current process's address space. It is not allowed to operate on another address space.

## **Execution Environment**

The as\_det64 kernel service can be called from the process environment only.

## **Return Values**

The region was successfully unmapped and deallocated.

EINVAL An attempt was made to deallocate a region that should not have been deallocated (that is, a base

kernel region, process text region, process private region, or unallocated region).

**EINVAL** Input address out of range.

## **Related Information**

The as\_att64 kernel service, as\_seth64 kernel service, as\_geth64 kernel service, as\_getsrval64 kernel service, as\_puth64 kernel service.

# as\_geth Kernel Service

# **Purpose**

Obtains a handle to the virtual memory object for the specified address given in the specified address space.

# **Syntax**

#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
#include <sys/adspace.h>
vmhandle\_t as\_geth (Adspacep, Addr)
adspace\_t \*Adspacep;
caddr t Addr;

#### **Parameters**

Adspacep Points to the address space structure to obtain the virtual memory object handle from.

Addr

Specifies the virtual memory address that should be used to determine the virtual memory object handle for the specified address space.

## **Description**

The as\_geth kernel service is used to obtain a handle to the virtual memory object corresponding to a virtual memory address in a particular address space. This handle can then be used with the vm\_att kernel service to make the object addressable in another address space.

This service can also be called from the interrupt environment.

## **Execution Environment**

The as\_geth kernel service can be called from the process environment only.

## Return Values

The as geth kernel service always succeeds and returns the appropriate handle.

## **Related Information**

The vm att kernel service.

## as\_geth64 Kernel Service

# **Purpose**

Obtains a handle to the virtual memory object for the specified address.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
#include <sys/adspace.h>
vmhandle_t as_geth64 (addr64)
unsigned long long addr64;
```

#### **Parameter**

addr64 Specifies the virtual memory address for which the corresponding handle should be returned.

# **Description**

The as\_geth64 kernel service is used to obtain a handle to the virtual memory object corresponding to the input address (addr64). This handle can then be used with the as\_att64 or vm\_att kernel service to make the object addressable at a different location.

After the last use of the handle and after it is detached accordingly, the as\_puth64 kernel service must be used to indicate this fact. Failure to call the as\_puth64 service may result in resources being permanently unavailable for re-use.

If the handle returned refers to a virtual memory segment, then that segment is protected from deletion until the as\_puth64 kernel service is called.

If, for some reason, it is known that the virtual memory object cannot be deleted, then the as getsrval64 kernel service may be used instead of the as geth64 service.

The as geth64 kernel service assumes an address space model of fixed-size virtual memory objects.

This service will operate correctly for both 32-bit and 64-bit user address spaces. It will also work for kernel processes (kprocs).

Note: This service only operates on the current process's address space. It is not allowed to operate on another address space.

#### **Execution Environment**

The as geth64 kernel service can be called from the process environment only.

## **Return Values**

On successful completion, this routine returns the appropriate handle.

On error, this routine returns the value INVLSID defined in sys/seg.h. This is caused by an address out of range.

Errors include: Input address out of range.

#### **Related Information**

The as att64 kernel service, as seth64 kernel service, as det64 kernel service, as getsrval64 kernel service, and as puth64 kernel service.

## as\_getsrval64 Kernel Service

## **Purpose**

Obtains a handle to the virtual memory object for the specified address.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/vmuser.h> #include <sys/adspace.h> vmhandle t as getsrval64 (addr64) unsigned long long addr64;

#### **Parameters**

addr64 Specifies the virtual memory address for which the corresponding handle should be returned.

# **Description**

The as **getsrval64** kernel service is used to obtain a handle to the virtual memory object corresponding to the input address(addr64). This handle can then be used with the as\_att64 or vm\_att kernel services to make the object addressable at a different location.

This service should only be used when it is known that the virtual memory object cannot be deleted, otherwise the as\_geth64 kernel service must be used.

The as\_puth64 kernel service must not be called for handles returned by the as\_getsrval64 kernel service.

The as getsrval64 kernel service assumes an address space model of fixed-size virtual memory objects.

This service will operate correctly for both 32-bit and 64-bit user address spaces. It will also work for kernel processes (*kprocs*).

**Note:** This service only operates on the current process's address space. It is not allowed to operate on another address space.

#### **Execution Environment**

The **as\_getsrval64** kernel service can be called from the process environment only when the current user address space is 64-bits. If the current user address space is 32-bits, or is a *kproc*, then **as\_getsrval64** may be called from an interrupt environment.

## **Return Values**

On successful completion this routine returns the appropriate handle.

On error, this routine returns the value INVLSID defined in **sys/seg.h**. This is caused by an address out of range.

Errors include: Input address out of range.

### **Related Information**

The as\_att64 kernel service, as\_det64 kernel service, as\_geth64 kernel service, and as\_puth64 kernel service, as\_seth64 kernel service.

## as\_lw\_att64 Kernel Service

# **Purpose**

Allocates and maps a specified region in the current user address space. Part of the lightweight kernel service subsystem, which must be initialized with the **as\_lw\_pool\_init** kernel service before it can be used.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/muser.h>
#include <sys/adspace.h>
#include <sys/mem.h>

int as_lw_att64 (dp, offset, length, addr)
xmem* dp;
size_t offset;
size_t length;
ptr64* addr;
```

### **Parameters**

dp Pointer to a cross memory descriptor that describes the virtual memory object that is being made

addressable in the address space.

offset Specifies the byte offset in the virtual memory object.

length Specifies the number of bytes to map in the virtual memory object.

addr Pointer to the location where the address will be returned.

## **Description**

The as\_lw\_att64 kernel service does the following:

- Allocates a region from the process' address space for the mapping.
- Maps the virtual memory object selected by the dp parameter.
- Constructs the address of the offset specified by the offset parameter within the user-address space.

Note: The as Iw att64 kernel service should be used with caution. Be sure to read the documentation for this and the other lightweight services (as\_lw\_det64 and as\_lw\_pool\_init) carefully before doing so. There is a risk of illegal data access and cross-process data corruption if these services are not used correctly.

In order to use this service, the cross memory descriptor pointed to by the dp parameter must be initialized by using the xmattach kernel service with the LW\_XMATTACH flag set. The lw\_pool\_init kernel service must also have been successfully called by the current process.

The service will map an area length bytes long into the caller's address space from the memory represented by the descriptor, starting at the number of bytes specified in the offset parameter. It is illegal for any thread other than the caller of this service to address the attached region.

This service will operate correctly only in 64-bit user address spaces. It will not work for kernel processes (kprocs).

Note: This service only operates on the current process's address space. It is not allowed to operate on another address space.

### **Execution Environment**

The as Iw att64 kernel service can be called from the process environment only.

#### **Return Values**

On successful completion, this service sets the value of addr to the address of the allocated region and returns 0.

NULL An error occurred and errno indicates the cause.

**EINVAL** Cross memory descriptor is in an invalid state, length is zero or offset plus length goes past the

end of the virtual memory object.

**ENODEV** The as\_lw\_pool\_init kernel service has not been called to initialize the pool settings for this

process.

**ENOSYS** Called by a 32-bit process.

**ENOSPC** Resources allocated to do lightweight services for this thread expended. Either the region to be

> attached is too large (the as\_lw\_pool\_init kernel service was called with too small a pool\_size) or there are outstanding attaches which need to release their lightweight resources using the

as\_lw\_det64 kernel service before this attach can be completed.

**EIO** Indicates a failure of the lightweight subsystem, process should discontinue use of lightweight

kernel services.

**EPERM** Called by a user thread that is not 1:1 with a kernel thread.

**ENOMEM** Could not allocate system resources for lightweight services for this thread.

# **Implementation Specifics**

The as Iw att64 kernel service is part of Base Operating System (BOS) Runtime.

#### **Related Information**

"as\_lw\_det64 Kernel Service" on page 21, "as\_lw\_pool\_init Kernel Service" on page 22.

## as\_lw\_det64 Kernel Service

## **Purpose**

Unmaps and deallocates a region in the current user address space that was mapped using the as\_lw\_att64 kernel service.

## **Syntax**

#include <sys/errno.h>
#include <sys/adspace.h>
#include <sys/xmem.h>
int as\_lw\_det64 (dp, addr, length)
xmem\* dp;
void\* addr;
size t length;

#### **Parameters**

dp The cross memory descriptor describing the attached virtual memory.addr Specifies the first effective address of the region to be deallocated.

length Specifies the length of the region to be deallocated.

## **Description**

**Note:** The **as\_lw\_det64** kernel service should be used with caution. Read the documentation for this and the other lightweight services (**as\_lw\_att64** and **as\_lw\_pool\_init**) carefully before doing so. There is a risk that illegal data accesses will be allowed if these services are not used correctly.

The **as\_lw\_det64** kernel service unmaps the virtual memory from the region starting at the specified effective address, which is specified by the *addr* parameter. This service (and only this service) must be used to unmap regions mapped by the **as\_lw\_att64** kernel service. It must be called by the same thread that called the **as\_lw\_att64** kernel service. The *addr* parameter must be the value returned by the **as\_lw\_att64** kernel service, and the *dp* parameter and the *length* parameter must be the same *dp* and *length* passed to it. The *xmdetach* kernel service must not be called to release the *dp* parameter until any outstanding attaches of the *dp* parameter using the **as\_lw\_att64** kernel service have been detached using the **as\_lw\_det64** kernel service.

The **as\_lw\_det64** kernel service cannot be used to detach a region not mapped by the **as\_lw\_att64** kernel service.

The **as\_lw\_det64** kernel service will operate correctly only for 64-bit user address spaces. It will not work for kernel processes (kprocs).

**Note:** This service only operates on the current process's address space. It is not allowed to operate on another address space.

#### **Execution Environment**

The as\_lw\_det64 kernel service can be called from the process environment only.

#### **Return Values**

The region was successfully unmapped and deallocated.

EINVAL An attempt was made to deallocate a region that should not have been deallocated.

**ENOSYS** The service was called by a 32-bit process.

**ENOMEM** No lightweight resources allocated to this thread.

**EIO** Indicates a failure of the lightweight subsystem, process should discontinue use of lightweight

kernel services.

**EPERM** Called by a user thread that is not 1:1 with a kernel thread.

## Implementation Specifics

The as\_lw\_det64 kernel service is part of Base Operating System (BOS) Runtime.

### **Related Information**

"as\_lw\_att64 Kernel Service" on page 19, "as\_lw\_pool\_init Kernel Service."

## as\_lw\_pool\_init Kernel Service

## **Purpose**

Initializes lightweight attach and detach subsystem for the current process with the given settings.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
#include <sys/adspace.h>
int as lw pool init (pool size, flags)
size t pool size;
uint flags;
```

#### **Parameters**

pool\_size Specifies the maximum number of bytes that can be attached by lightweight services at

one time by each thread of this process.

Specifies flag options for this kernel service. Valid values are 0 and LW DEBUG. flags

# **Description**

Note: The as Iw pool init kernel service should be used with caution. Read the documentation for this and the other lightweight services (as Iw att64 and as Iw det64) carefully before doing so. There is a risk that illegal data accesses will be allowed if these services are not used correctly.

The as Iw pool init kernel service initializes the lightweight pool size and flag settings for the current process. Once it has been called, these settings are fixed and cannot be changed for the process.

If LW DEBUG is set in the flags parameter, the risk of illegal data access will be removed from calls to the as\_lw\_att64 kernel service and the as\_lw\_det64 kernel service. This setting allows users to debug problems that are caused by incorrect use of these services.

Processes that have called the as Iw pool init kernel service can use the other lightweight kernel services (as\_lw\_att64 and as\_lw\_det64) to attach and detach virtual memory regions represented by a cross memory descriptor. These kernel services are used on a per-thread basis, that is if one thread uses the as\_lw\_att64 kernel service to attach virtual memory to a region of its address space, that region cannot be addressed by any other thread, and it must be detached by the same thread by using the as\_lw\_det64 kernel service.

This service will operate correctly only for 64-bit user address spaces. It will not work for kernel processes (kprocs).

### **Execution Environment**

The as\_lw\_pool\_init kernel service can be called from a 64-bit process environment only.

### **Return Values**

On successful completion, this service returns 0.

**ENOSYS** The service was called by a 32-bit process.

**EEXIST** The **as\_lw\_pool\_init** kernel service has already been successfully completed for this

process.

EINVAL Invalid flag settings or the *pool\_size* parameter is 0.

EPERM Called by a user thread that is not 1:1 with a kernel thread.

## Implementation Specifics

The as\_lw\_pool\_init kernel service is part of Base Operating System (BOS) Runtime.

### **Related Information**

"as\_lw\_att64 Kernel Service" on page 19, "as\_lw\_det64 Kernel Service" on page 21.

## as\_puth64 Kernel Service

## **Purpose**

Indicates that no more references will be made to a virtual memory object obtained using the **as\_geth64** kernel service.

# **Syntax**

#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
#include <sys/adspace.h>
int as\_puth64 ( addr64, vmhandle )
unsigned long long addr64;
vmhandle\_t vmhandle;

### **Parameters**

addr64 Specifies the virtual memory address that the virtual memory object handle was obtained from. This

must be the same address that was given to the as geth64 kernel service previously.

vmhandle Describes the virtual memory object that will no longer be referenced. This handle must have been

returned by the as\_geth64 kernel service.

# **Description**

The **as\_puth64** kernel service is used to indicate that no more references will be made to the virtual memory object returned by a call to the **as\_geth64** kernel service. The virtual memory object must be detached from the address space already, using either **as\_det64** or **vm\_det** service.

Failure to call the **as\_puth64** kernel service may result in resources being permanently unavailable for re-use.

If, for some reason, it is known that the virtual memory object cannot be deleted, the as getsrval64 kernel service may be used instead of the as geth64 kernel service. This kernel service does not require that the as\_puth64 kernel service be used.

The as\_puth64 kernel service assumes an address space model of fixed-size virtual memory objects.

This service will operate correctly for both 32-bit and 64-bit user address spaces. It will also work for kernel processes (kprocs).

Note: This service only operates on the current process's address space. It is not allowed to operate on another address space.

### **Execution Environment**

The as\_puth64 kernel service can be called from the process environment only.

### **Return Values**

Successful completion. **EINVAL** Input address out of range.

### **Related Information**

The as\_att64 kernel service, as\_det64 kernel service, as\_getsrval64 kernel service, as\_geth64 kernel service, and as\_seth64 kernel service.

## as seth64 Kernel Service

# **Purpose**

Maps a specified region for the specified virtual memory object.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
#include <sys/adspace.h>
int as_seth64 (addr64, vmhandle)
unsigned long long addr64;
vmhandle t vmhandle;
```

#### **Parameters**

addr64 The region covering this input virtual memory address will be mapped.

Describes the virtual memory object being made addressable within a region of the address space. vmhandle

# **Description**

The as\_seth64 kernel service maps the region covering the input addr64 parameter. Any virtual memory object previously mapped within this region is unmapped.

The virtual memory object specified with the vmhandle parameter is then mapped with the access permission specified in the handle.

The **as\_seth64** kernel service should only be used when it is necessary to map a virtual memory object at a fixed address. The **as\_att64** kernel service should be used when it is not absolutely necessary to map the virtual memory object at a fixed address.

The as\_seth64 kernel service assumes an address space model of fixed-size virtual memory objects.

This service will operate correctly for both 32-bit and 64-bit user address spaces. It will also work for kernel processes (*kprocs*).

**Note:** This service only operates on the current process's address space. It is not allowed to operate on another address space.

#### **Execution Environment**

The as\_seth64 kernel service can be called from the process environment only.

### **Return Values**

Successful completion.EINVAL Input address out of range.

### **Related Information**

The as\_att64 kernel service, as\_det64 kernel service, as\_getsrval64 kernel service, as\_geth64 kernel service, and as\_puth64 kernel service.

## attach Device Queue Management Routine

# **Purpose**

Provides a means for performing device-specific processing when the attchq kernel service is called.

# **Syntax**

#include <sys/types.h>
#include <sys/errno.h>
#include <sys/deviceq.h>
int attach ( dev\_parms, path\_id)
caddr\_t dev\_parms;
cba id path id;

### **Parameters**

dev\_parms Passed to the creatd kernel service when the attach routine is defined.

path\_id Specifies the path identifier for the gueue being attached to.

# **Description**

The **attach** routine is part of the Device Queue Management kernel extension. Each device queue can have an **attach** routine. This routine is optional and must be specified when the **creatd** kernel service defines the device queue. The **attchq** service calls the **attach** routine each time a new path is created to the owning device queue. The processing performed by this routine is dependent on the server function.

The **attach** routine executes under the process under which the **attchq** kernel service is called. The kernel does not serialize the execution of this service with the execution of any other server routines.

### **Execution Environment**

The attach-device routine can be called from the process environment only.

### **Return Values**

Indicates a successful completion. RC GOOD

RC\_NONE Indicates that resources such as pinned memory are unavailable.

RC MAX Indicates that the server already has the maximum number of users that it

supports.

Greater than or equal to RC\_DEVICE Indicates device-specific errors.

# audit\_svcbcopy Kernel Service

## **Purpose**

Appends event information to the current audit event buffer.

## **Syntax**

#include <sys/types.h> #include <sys/errno.h> int audit svcbcopy (buf, len) char \*buf; int len;

### **Parameters**

buf Specifies the information to append to the current audit event record buffer.

len Specifies the number of bytes in the buffer.

# **Description**

The audit svcbcopy kernel service appends the specified buffer to the event-specific information for the current switched virtual circuit (SVC). System calls should initialize auditing with the audit svcstart kernel service, which creates a record buffer for the named event.

The audit svcbcopy kernel service can then be used to add additional information to that buffer. This information usually consists of system call parameters passed by reference.

If auditing is enabled, the information is written by the audit\_svcfinis kernel service after the record buffer is complete.

#### **Execution Environment**

The **audit svcbcopy** kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

ENOMEM Indicates that the kernel service is unable to allocate space for the new buffer.

### **Related Information**

The audit\_svcfinis kernel service, audit\_svcstart kernel service.

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# audit\_svcfinis Kernel Service

## **Purpose**

Writes an audit record for a kernel service.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/audit.h>
int audit svcfinis ()
```

## **Description**

The audit\_svcfinis kernel service completes an audit record begun earlier by the audit\_svcstart kernel service and writes it to the kernel audit logger. Any space allocated for the record and associated buffers is freed.

If the system call terminates without calling the audit\_svcfinis service, the switched virtual circuit (SVC) handler exit routine writes the records. This exit routine calls the audit\_svcfinis kernel service to complete the records.

### **Execution Environment**

The audit\_svcfinis kernel service can be called from the process environment only.

### **Return Values**

The audit\_svcfinis kernel service always returns a value of 0.

## **Related Information**

The audit\_svcbcopy kernel service, audit\_svcstart kernel service.

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## audit svcstart Kernel Service

# **Purpose**

Initiates an audit record for a system call.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/audit.h>
int audit_svcstart (eventnam, eventnum, numargs, arg1, arg2, ...)
char * eventnam;
int * eventnum;
int numargs;
```

```
int arg1;
int arg2;
```

### **Parameters**

eventnam Specifies the name of the event. In the current implementation, event names must be

less than 17 characters, including the trailing null character. Longer names are

truncated.

eventnum Specifies the number of the event. This is an internal table index meaningful only to the

kernel audit logger. The system call should initialize this parameter to 0. The first time the audit\_svcstart kernel service is called, this parameter is set to the actual table index. The system call should not reset the parameter. The parameter should be

declared a static.

numargs Specifies the number of parameters to be included in the buffer for this record. These

parameters are normally zero or more of the system call parameters, although this is

not a requirement.

arg1, arg2, ... Specifies the parameters to be included in the buffer.

## Description

The audit\_svcstart kernel service initiates auditing for a system call event. It dynamically allocates a buffer to contain event information. The arguments to the system call (which should be specified as parameters to this kernel service) are automatically added to the buffer, as is the internal number of the event. You can use the audit svcbcopy service to add additional information that cannot be passed by value.

The system call commits this record with the audit\_svcfinis kernel service. The system call should call the audit\_svcfinis kernel service before calling another system call.

### **Execution Environment**

The audit\_svcstart kernel service can be called from the process environment only.

#### **Return Values**

Nonzero Indicates that auditing is on for this routine. n Indicates that auditing is off for this routine.

# **Example**

```
svccrash(int x, int y, int z)
        static int eventnum;
        if (audit_svcstart("crashed", &eventnum, 2, x, y))
                 audit svcfinis();
        body of svccrash
}
```

The preceding example allocates an audit event record buffer for the crashed event and copies the first and second arguments into it. The third argument is unnecessary and not copied.

#### Related Information

The audit\_svcbcopy kernel service, audit\_svcfinis kernel service.

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### bawrite Kernel Service

## **Purpose**

Writes the specified buffer data without waiting for I/O to complete.

## **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/buf.h> int bawrite ( bp) struct buf \*bp;

#### **Parameter**

bp Specifies the address of the buffer structure.

On a platform that supports storage keys, the passed in *bp* parameter must be in the **KKEY\_PUBLIC** or **KKEY\_BLOCK\_DEV** protection domain.

# **Description**

The **bawrite** kernel service sets the asynchronous flag in the specified buffer and calls the **bwrite** kernel service to write the buffer.

For a description of how the three buffer-cache write subroutines work, see "Block I/O Buffer Cache Services: Overview" in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

#### **Execution Environment**

The **bawrite** kernel service can be called from the process environment only.

### **Return Values**

0 Indicates successful completion.

**ERRNO** Returns an error number from the /usr/include/sys/errno.h file on error.

### **Related Information**

The bwrite kernel service.

Block I/O Buffer Cache Kernel Services: Overview and I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### **bdwrite Kernel Service**

## **Purpose**

Releases the specified buffer after marking it for delayed write.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
void bdwrite ( bp)
struct buf *bp;
```

### **Parameter**

Specifies the address of the buffer structure for the buffer to be written. bp

On a platform that supports storage keys, the passed in bp parameter must be in the KKEY\_PUBLIC or KKEY\_BLOCK\_DEV protection domain.

## **Description**

The **bdwrite** kernel service marks the specified buffer so that the block is written to the device when the buffer is stolen. The **bdwrite** service marks the specified buffer as delayed write and then releases it (that is, puts the buffer on the free list). When this buffer is reassigned or reclaimed, it is written to the device.

For a description of how the three buffer-cache write subroutines work, see "Block I/O Buffer Cache Kernel Services: Overview" in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### **Execution Environment**

The **bdwrite** kernel service can be called from the process environment only.

### **Return Values**

The **bdwrite** kernel service has no return values.

#### Related Information

The brelse kernel service.

Block I/O Buffer Cache Kernel Services: Overview and I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### bflush Kernel Service

# **Purpose**

Flushes all write-behind blocks on the specified device from the buffer cache.

# **Syntax**

```
#include <svs/tvpes.h>
#include <sys/errno.h>
#include <sys/buf.h>
void bflush ( dev)
dev t dev;
```

#### **Parameter**

dev Specifies which device to flush. A value of NODEVICE flushes all devices.

## **Description**

The **bflush** kernel service runs the free list of buffers. It notes as busy or writing any dirty buffer whose block is on the specified device. When a value of **NODEVICE** is specified, the **bflush** service flushes all write-behind blocks for all devices. The **bflush** service has no return values.

### **Execution Environment**

The **bflush** kernel service can be called from the process environment only.

### **Related Information**

The **bwrite** kernel service.

Block I/O Buffer Cache Kernel Services: Overview and I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# bindprocessor Kernel Service

## **Purpose**

Binds or unbinds kernel threads to a processor.

## **Syntax**

```
#include <sys/processor.h>
int bindprocessor ( What, Who, Where)
int What;
int Who;
cpu t Where;
```

#### **Parameters**

What

Specifies whether a process or a kernel thread is being bound to a processor. The *What* parameter can take one of the following values:

#### **BINDPROCESS**

A process is being bound to a processor.

#### **BINDTHREAD**

A kernel thread is being bound to a processor.

Who

Indicates a process or kernel thread identifier, as appropriate for the *What* parameter, specifying the process or kernel thread which is to be bound to a processor.

Where

If the *Where* parameter is in the range 0-n (where n is the number of online processors in the system), it represents a bind CPU identifier to which the process or kernel thread is to be bound. Otherwise, it represents a processor class, from which a processor will be selected. A value of

PROCESSOR\_CLASS\_ANY unbinds the specified process or kernel thread, which will then be able to run on any processor.

# **Description**

The **bindprocessor** kernel service binds a single kernel thread, or all kernel threads in a process, to a processor, forcing the bound threads to be scheduled to run on that processor only. It is important to understand that a process itself is not bound, but rather its kernel threads are bound. Once kernel threads are bound, they are always scheduled to run on the chosen processor, unless they are later unbound. When a new thread is created using the **thread\_create** kernel service, it has the same bind properties as its creator.

Programs that use processor bindings should become Dynamic Logical Partitioning (DLPAR) aware. Refer to Dynamic Logical Partitioning in AIX Version 7.1 General Programming Concepts: Writing and Debugging Programs for more information.

### **Return Values**

On successful completion, the bindprocessor kernel service returns 0. Otherwise, a value of -1 is returned and the error code can be checked by calling the getuerror kernel service.

### **Error Codes**

The bindprocessor kernel service is unsuccessful if one of the following is true:

**EINVAL** The What parameter is invalid, or the Where parameter indicates an invalid processor number or a

processor class which is not currently available.

**ESRCH** The specified process or thread does not exist.

**EPERM** The caller does not have root user authority, and the Who parameter specifies either a process, or a

thread belonging to a process, having a real or effective user ID different from that of the calling process.

## **Execution Environment**

The bindprocessor kernel service can be called from the process environment only.

### Related Information

The **bindprocessor** command.

### binval Kernel Service

# **Purpose**

Makes nonreclaimable all blocks in the buffer cache of a specified device.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
void binval ( dev)
dev t dev;
```

#### **Parameter**

Specifies the device to be purged.

# **Description**

The binval kernel service makes nonreclaimable all blocks in the buffer cache of a specified device. Before removing the device from the system, use the binval service to remove the blocks.

All of blocks of the device to be removed need to be flushed before you call the binval service. Typically, these blocks are flushed after the last close of the device.

### **Execution Environment**

The **binval** kernel service can be called from the process environment only.

#### **Return Values**

The binval service has no return values.

### **Related Information**

The bflush kernel service, blkflush kernel service.

Block I/O Buffer Cache Kernel Services: Overview and I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### blkflush Kernel Service

## **Purpose**

Flushes the specified block if it is in the buffer cache.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>

int blkflush ( dev, blkno)
dev_t dev;
daddr_t blkno;
```

### **Parameters**

dev Specifies the device containing the block to be flushed.

blkno Specifies the block to be flushed.

# **Description**

The **blkflush** kernel service checks to see if the specified buffer is in the buffer cache. If the buffer is not in the cache, then the **blkflush** service returns a value of 0. If the buffer is in the cache, but is busy, the **blkflush** service calls the **e\_sleep** service to wait until the buffer is no longer in use. Upon waking, the **blkflush** service tries again to access the buffer.

If the buffer is in the cache and is not busy, but is dirty, then it is removed from the free list. The buffer is then marked as busy and synchronously written to the device. If the buffer is in the cache and is neither busy nor dirty (that is, the buffer is already clean and therefore does not need to be flushed), the **blkflush** service returns a value of 0.

### **Execution Environment**

The **blkflush** kernel service can be called from the process environment only.

#### **Return Values**

- 1 Indicates that the block was successfully flushed.
- Indicates that the block was not flushed. The specified buffer is either not in the buffer cache or is in the buffer cache but neither busy nor dirty.

### **Related Information**

The bwrite kernel service.

Block I/O Buffer Cache Kernel Services: Overview I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### bread Kernel Service

## **Purpose**

Reads the specified block data into a buffer.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
struct buf *bread ( dev, blkno)
dev t dev;
daddr_t blkno;
```

#### **Parameters**

dev Specifies the device containing the block to be read.

blkno Specifies the block to be read.

## **Description**

The **bread** kernel service assigns a buffer to the given block. If the specified block is already in the buffer cache, then the block buffer header is returned. Otherwise, a free buffer is assigned to the specified block and the data is read into the buffer. The bread service waits for I/O to complete to return the buffer header.

The buffer is allocated to the caller and marked as busy.

#### **Execution Environment**

The bread kernel service can be called from the process environment only.

#### Return Values

The bread service returns the address of the selected buffer's header. A nonzero value for B\_ERROR in the b flags field of the buffer's header (buf structure) indicates an error. If this occurs, the caller should release the buffer associated with the block using the brelse kernel service.

On a platform that supports storage keys, the buffer header is allocated from the storage protected by the KKEY BLOCK DEV kernel key.

### Related Information

The getblk kernel service, iowait kernel service.

Block I/O Buffer Cache Kernel Services: Overview in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts describes how the buffer cache services manage the block I/O buffer cache mechanism.

### breada Kernel Service

## **Purpose**

Reads in the specified block and then starts I/O on the read-ahead block.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>

struct buf *breada ( dev, blkno, rablkno)
dev_t dev;
daddr_t blkno;
daddr t rablkno;
```

#### **Parameters**

dev Specifies the device containing the block to be read.

blkno Specifies the block to be read.

rablkno Specifies the read-ahead block to be read.

## **Description**

The **breada** kernel service assigns a buffer to the given block. If the specified block is already in the buffer cache, then the **bread** service is called to:

- · Obtain the block.
- · Return the buffer header.

Otherwise, the **getblk** service is called to assign a free buffer to the specified block and to read the data into the buffer. The **breada** service waits for I/O to complete and then returns the buffer header.

I/O is also started on the specified read-ahead block if the free list is not empty and the block is not already in the cache. However, the **breada** service does not wait for I/O to complete on this read-ahead block.

"Block I/O Buffer Cache Kernel Services: Overview" in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts summarizes how the **getblk**, **bread**, **breada**, and **brelse** services uniquely manage the block I/O buffer cache.

#### **Execution Environment**

The breada kernel service can be called from the process environment only.

#### **Return Values**

The **breada** service returns the address of the selected buffer's header. A nonzero value for B\_ERROR in the b\_flags field of the buffer header (**buf** structure) indicates an error. If this occurs, the caller should release the buffer associated with the block using the **brelse** kernel service.

On a platform that supports storage keys, the buffer header is allocated from the storage protected by the **KKEY BLOCK DEV** kernel key.

### **Related Information**

The **bread** kernel service, **iowait** kernel service.

The **ddstrategy** device driver entry point.

Block I/O Buffer Cache Kernel Services: Overview and I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## brelse Kernel Service

## **Purpose**

Frees the specified buffer.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
void brelse ( bp)
struct buf *bp;
```

### **Parameter**

Specifies the address of the **buf** structure to be freed.

On a platform that supports storage keys, the passed in bp parameter must be in the KKEY\_PUBLIC or KKEY\_BLOCK\_DEV protection domain.

# **Description**

The **brelse** kernel service frees the buffer to which the bp parameter points.

The brelse kernel service awakens any processes waiting for this buffer or for another free buffer. The buffer is then put on the list of available buffers. The buffer is also marked as not busy so that it can either be reclaimed or reallocated.

The brelse service has no return values.

## **Execution Environment**

The brelse kernel service can be called from either the process or interrupt environment.

#### **Related Information**

The geteblk kernel service.

The **buf** structure.

Block I/O Buffer Cache Kernel Services: Overview and I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## bsr\_alloc Kernel Service

## **Purpose**

Allocates a Barrier Synchronization Register (BSR) resource, and retrieves mapping information.

## **Syntax**

```
#include <sys/adspace.h>
int bsr_alloc (
  int bsr_bytes,
  struct io_map * bsr_map,
  int *bsr_stride,
  int *bsr id)
```

### **Parameters**

bsr\_bytes Number of BSR bytes wanted.

bsr\_map Mapping information for the BSR facility

bsr\_stride Stride at which the BSR bytes repeat within the mapping bsr\_id An opaque identifier for the allocated BSR resource

## **Description**

The **bsr\_alloc** service can be used to allocate and reserve all or a portion of the BSR facility. The requested number of BSR bytes to allocate is communicated through the *bsr\_bytes* parameter. The requested number of bytes must correspond to a supported window size, as communicated by the *supported\_window\_mask* parameter of the **bsr\_query** service. If the requested number of bytes is available, the bytes are reserved and the I/O mapping information for accessing the allocated facility is written to the *bsr\_map* structure. In addition, the stride within the mapping that the allocated BSR bytes repeat is recorded in the *bsr\_stride* field. The *bsr\_id* field is written with a unique identifier to be used with the **bsr free** call.

If multiple granules or windows are to be used, they must be allocated with independent calls to **bsr\_alloc**. this is because I/O mappings for multiple granules might not be contiguous, and strides are only applicable within the granule.

The resulting *bsr\_map* information can then be used as input to **rmmap\_create** for establishing addressability to the BSR resource within the current process address space.

### **Execution Environment**

The **bsr\_alloc** service can only be called from the process environment.

#### **Return Values**

If successful, **bsr\_alloc** returns 0 and modifies the *bsr\_map* structure so that it contains the mapping information for the newly allocated resource, modifies the *bsr\_stride* field displays the stride on which the BSR bytes repeat within the mapping, and modifies the *bsr\_id* field so that it displays a unique identifier for the newly allocated BSR resource. If unsuccessful, one of the following values is returned:

**ENODEV** The BSR facility does not exist.

**EINVAL** Unsupported number of bytes requested.

**EBUSY** Requested BSR bytes or mappable BSR windows are currently in use.

### **Related Information**

The "bsr\_free Kernel Service," "bsr\_query Kernel Service," "rmmap\_create Kernel Service" on page 435.

## bsr free Kernel Service

## **Purpose**

Frees a Barrier Synchronization Register (BSR) resource previously allocated with the bsr alloc kernel service.

## **Syntax**

```
#include <sys/adspace.h>
int bsr_free (
int bsr_id,
```

### **Parameters**

bsr\_id

BSR resource identifier as returned in the bsr\_id field of the bsr\_alloc call.

## **Description**

The bsr\_free service releases a BSR allocation. The specific BSR resource being freed is identified by the unique identifier *bsr id* from the corresponding **bsr alloc** call.

It is the caller's responsibility to ensure that all prior attachments to the BSR resource, through rmmap create calls, have been detached with corresponding rmmap remove calls prior to freeing the BSR resource.

### **Execution Environment**

The bsr\_free service can only be called from the process environment.

### **Return Values**

A successful operation. **ENODEV** The BSR facility is not present.

EINVAL BSR resource corresponding to bsr\_id is invalid or not currently allocated.

#### **Related Information**

The "bsr\_alloc Kernel Service" on page 37, "bsr\_query Kernel Service," "rmmap\_remove Kernel Service" on page 439.

# bsr\_query Kernel Service

# **Purpose**

Queries the existence of the Barrier Synchronization Register facility, and, if it exists, its size and allocation granule.

## **Syntax**

```
#include <sys/adspace.h>
int bsr_query (
  int *total_bytes,
  uint * supported_window_mask,
  int *free_bytes,
  uint *free_window_mask)
```

### **Parameters**

total\_bytes Total bytes of the BSR facility currently present within the system or logical partition supported\_window\_mask

Bit mask representing supported power-of-2-sized windows that can be allocated

free\_bytes Number of BSR bytes currently available (not allocated)

free\_window\_mask Bit mask representing available (not allocated) power-of-2-sized windows

## **Description**

The **bsr\_query** service can be used to detect the presence and capabilities of the Barrier Synchronization Register (BSR) facility on a given system or logical partition. If the BSR facility is present on a system or within a logical partition, a value of 0 is returned, and the parameters, passed by reference, are written with the appropriate information.

The *total\_bytes* field is written with the total number of BSR bytes currently present in the system or logical partition. The *supported\_window\_mask* field is written with a bitmask, where each bit set indicates the various power-of-2 window sizes that the *total\_bytes* can be allocated and accessed. For example, a mask of 0x58 would indicate that windows of size 64 (0x40), 16 (0x10), and 8 (0x8) bytes were supported.

The *free\_bytes* field is written with the number of BSR bytes within the system or logical partition that are currently unallocated. The *free\_window\_mask* field is written with a bitmask, where each bit set indicates the power-of-2 window sizes that are available for allocating and accessing the remaining *free\_bytes*.

Note: Due to dynamic reconfiguration, the information returned by this query service might become stale.

#### **Execution Environment**

The **bsr query** service can only be called from the process environment.

#### **Return Values**

The BSR facility exists and information is provided.

**ENODEV** The BSR facility does not exist.

#### **Related Information**

The "bsr\_alloc Kernel Service" on page 37, "bsr\_free Kernel Service" on page 38.

### **bwrite Kernel Service**

## **Purpose**

Writes the specified buffer data.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
int bwrite ( bp)
struct buf *bp;
```

#### **Parameter**

bp Specifies the address of the buffer structure for the buffer to be written.

On a platform that supports storage keys, the passed in bp parameter must be in the KKEY\_PUBLIC or KKEY BLOCK DEV protection domain.

## **Description**

The bwrite kernel service writes the specified buffer data. If this is a synchronous request, the bwrite service waits for the I/O to complete.

"Block I/O Buffer Cache Kernel Services: Overview" in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts describes how the three buffer-cache write routines work.

### **Execution Environment**

The **bwrite** kernel service can be called from the process environment only.

## **Return Values**

Indicates a successful operation.

**ERRNO** Returns an error number from the /usr/include/sys/errno.h file on error.

#### **Related Information**

The brelse kernel service, iowait kernel service.

I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# cancel Device Queue Management Routine

# **Purpose**

Provides a means for cleaning up queue element-related resources when a pending queue element is eliminated from the queue.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/deviceq.h>
void cancel ( ptr)
struct req qe *ptr;
```

### **Parameter**

ptr Specifies the address of the queue element.

## **Description**

The kernel calls the **cancel** routine to clean up resources associated with a queue element. Each device queue can have a **cancel** routine. This routine is optional and must be specified when the device queue is created with the **creatq** service.

The **cancel** routine is called when a pending queue element is eliminated from the queue. This occurs when the path is destroyed or when the **canclq** service is called. The device manager should unpin any data and detach any cross-memory descriptor.

Any operations started as a result of examining the queue with the **peekq** service must be stopped.

The **cancel** routine is also called when a queue is destroyed to get rid of any pending or active queue elements.

### **Execution Environment**

The cancel-queue-element routine can be called from the process environment only.

## cfgnadd Kernel Service

## **Purpose**

Registers a notification routine to be called when system-configurable variables are changed.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/sysconfig.h>

void cfgnadd
( cbp)
struct cfgncb *cbp;
```

### **Parameter**

cbp Points to a **cfgncb** configuration notification control block.

On a platform that supports storage keys, the passed in *cbp* parameter must only be in the **KKEY\_PUBLIC** domain.

# **Description**

The **cfgnadd** kernel service adds a **cfgncb** control block to the list of **cfgncb** structures that the kernel maintains. A **cfgncb** control block contains the address of a notification routine (in its cfgncb.func field) to be called when a configurable variable is being changed.

The SYS\_SETPARMS sysconfig operation allows a user with sufficient authority to change the values of configurable system parameters. The **cfgnadd** service allows kernel routines and extensions to register the notification routine that is called whenever these configurable system variables have been changed.

This notification routine is called in a two-pass process. The first pass performs validity checks on the proposed changes to the system parameters. During the second pass invocation, the notification routine performs whatever processing is needed to make these changes to the parameters. This two-pass procedure ensures that variables used by more than one kernel extension are correctly handled.

To use the **cfgnadd** service, the caller must define a **cfgncb** control block using the structure found in the /usr/include/sys/sysconfig.h file.

### **Execution Environment**

The **cfgnadd** kernel service can be called from the process environment only.

The **cfgncb.func** notification routine is called in a process environment only.

### **Related Information**

The sysconfig subroutine.

The **cfgncb** configuration notification control block.

The cfgndel kernel service.

Kernel Extension and Device Driver Management Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## cfgncb Configuration Notification Control Block

## **Purpose**

Contains the address of a notification routine that is invoked each time the sysconfig subroutine is called with the SYS\_SETPARMS command.

# **Syntax**

```
int func (cmd, cur, new)
int cmd;
struct var *cur:
struct var *new;
```

### **Parameters**

Indicates the current operation type. Possible values are CFGV\_PREPARE and CFGV\_COMMIT, as defined in the /usr/include/sys/sysconfig.h file.

cur Points to a var structure representing the current values of system-configurable variables.

new Points to a var structure representing the new or proposed values of system-configurable variables.

The *cur* and *new* **var** structures are both in the system address space.

# **Description**

The configuration notification control block contains the address of a notification routine. This structure is intended to be used as a list element in a list of similar control blocks maintained by the kernel.

Each control block has the following definition:

The **cfgndel** or **cfgnadd** kernel service can be used to add or delete a **cfgncb** control block from the **cfgncb** list. To use either of these kernel services, the calling routine must define the **cfgncb** control block. This definition can be done using the **/usr/include/sys/sysconfig.h** file.

Every time a SYS\_SETPARMS sysconfig command is issued, the sysconfig subroutine iterates through the kernel list of cfgncb blocks, invoking each notification routine with a CFGV\_PREPARE command. This call represents the first pass of what is for the notification routine a two-pass process.

On a **CFGV\_PREPARE** command, the **cfgncb.func** notification routine should determine if any values of interest have changed. All changed values should be checked for validity. If the values are valid, a return code of 0 should be returned. Otherwise, a return value indicating the byte offset of the first field in error in the *new* **var** structure should be returned.

If all registered notification routines create a return code of 0, then no value errors have been detected during validity checking. In this case, the **sysconfig** subroutine issues its second pass call to the **cfgncb.func** routine and sends the same parameters, although the *cmd* parameter contains a value of **CFGV\_COMMIT**. This indicates that the new values go into effect at the earliest opportunity.

An example of notification routine processing might be the following. Suppose the user wishes to increase the size of the block I/O buffer cache. On a **CFGV\_PREPARE** command, the block I/O notification routine would verify that the proposed new size for the cache is legal. On a **CFGV\_COMMIT** command, the notification routine would then make the additional buffers available to the user by chaining more buffers onto the existing list of buffers.

### **Related Information**

The **cfgnadd** kernel service, **cfgndel** kernel service.

The **SYS\_SETPARMS** sysconfig operation.

Kernel Extension and Device Driver Management Kernel Services in *AIX Version 7.1 Kernel Extensions* and *Device Support Programming Concepts*.

# cfgndel Kernel Service

# **Purpose**

Removes a notification routine for receiving broadcasts of changes to configurable system variables.

# **Syntax**

#include <sys/types.h>
#include <sys/errno.h>
#include <sys/sysconfig.h>
void cfgndel ( cbp)
struct cfgncb \*cbp;

## **Parameter**

Points to a **cfgncb** configuration notification control block.

On a platform that supports storage keys, the passed in cbp parameter must only be in the KKEY\_PUBLIC domain.

## **Description**

The **cfgndel** kernel service removes a previously registered **cfgncb** configuration notification control block from the list of cfgncb structures maintained by the kernel. This service thus allows kernel routines and extensions to remove their notification routines from the list of those called when a configurable system variable has been changed.

The address of the cfgncb structure passed to the cfgndel kernel service must be the same address used to call the **cfgnadd** service when the structure was originally added to the list. The /usr/include/sys/sysconfig.h file contains a definition of the cfgncb structure.

### **Execution Environment**

The **cfgndel** kernel service can be called from the process environment only.

### **Return Values**

The **cfgndel** service has no return values.

### **Related Information**

The **sysconfig** subroutine.

The **cfgncb** configuration notification control block.

The cfgnadd kernel service.

Kernel Extension and Device Driver Management Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# check Device Queue Management Routine

# **Purpose**

Provides a means for performing device-specific validity checking for parameters included in request queue elements.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/deviceq.h>
int check ( type, ptr, length)
int type;
struct req qe *ptr;
int length;
```

#### **Parameters**

type Specifies the type of call. The following values are used when the kernel calls the **check** routine:

CHECK\_PARMS + SEND\_CMD

Send command queue element.

CHECK\_PARMS + START\_IO

Start I/O CCB queue element.

CHECK\_PARMS + GEN\_PURPOSE

General purpose queue element. Specifies the address of the queue element.

ptr Specifies the address of the queue elemenlength Specifies the length of the queue element.

## **Description**

The **check** routine is part of the Device Queue Management Kernel extension. Each device queue can have a **check** routine. This routine is optional and must be specified when the device queue is created with the **creatq** service. The **enque** service calls the **check** routine before a request queue element is put on the device queue. The kernel uses the routine's return value to determine whether to put the queue element on the device queue or to stop the request.

The kernel does not call the **check** routine when an acknowledgment or control queue element is sent. Therefore, the **check** routine is only called while executing within a process.

The address of the actual queue element is passed to this routine. In the **check** routine, take care to alter only the fields that were meant to be altered. This routine does not need to be serialized with the rest of the server's routines, because it is only checking the parameters in the queue element.

The **check** routine can check the request before the request queue element is placed on the device queue. The advantage of using this routine is that you can filter out unacceptable commands before they are put on the device queue.

The routine looks at the queue element and returns **RC\_GOOD** if the request is acceptable. If the return code is not **RC\_GOOD**, the kernel does not place the queue element in a device queue.

### **Execution Environment**

The **check** routine executes under the process environment of the requester. Therefore, access to data areas must be handled as if the routine were in an interrupt handler environment. There is, however, no requirement to pin the code and data as in a normal interrupt handler environment.

### **Return Values**

**RC\_GOOD** Indicates successful completion.

All other return values are device-specific.

### **Related Information**

The enque kernel service.

### clrbuf Kernel Service

## **Purpose**

Sets the memory for the specified buffer structure's buffer to all zeros.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
void clrbuf ( bp)
struct buf *bp;
```

#### **Parameter**

bp Specifies the address of the buffer structure for the buffer to be cleared.

On a platform that supports storage keys, the passed in bp parameter must be in the KKEY\_PUBLIC or KKEY\_BLOCK\_DEV protection domain.

## **Description**

The cirbuf kernel service clears the buffer associated with the specified buffer structure. The cirbuf service does this by setting to 0 the memory for the buffer that contains the specified buffer structure.

### **Execution Environment**

The **cirbuf** kernel service can be called from either the process or interrupt environment.

### **Return Values**

The cirbuf service has no return values.

#### **Related Information**

Block I/O Buffer Cache Kernel Services: Overview and I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# clrimpx Kernel Service

# **Purpose**

Removes a saved context by popping the last saved jump buffer from the list of saved contexts.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
void clrjmpx ( jump buffer)
label_t *jump buffer;
```

#### **Parameter**

jump\_buffer

Specifies the address of the caller-supplied jump buffer that was specified on the call to the setjmpx service.

## **Description**

The **clrjmpx** kernel service pops the most recent context saved by a call to the **setjmpx** kernel service. Since each **longjmpx** call automatically pops the jump buffer for the context to resume, the **clrjmpx** kernel service should be called only following:

- · A normal return from the setimpx service when the saved context is no longer needed
- Any code to be run that requires the saved context to be correct

The **clrjmpx** service takes the address of the jump buffer passed in the corresponding **setjmpx** service.

### **Execution Environment**

The cirjmpx kernel service can be called from either the process or interrupt environment.

### **Return Values**

The clrjmpx service has no return values.

### **Related Information**

The longjmpx kernel service, setjmpx kernel service.

Process and Exception Management Kernel Services and Understanding Exception Handling in *AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts*.

## common\_reclock Kernel Service

## **Purpose**

Implements a generic interface to the record locking functions.

# **Syntax**

```
#include <sys/types.h>
#include <sys/flock.h>
common_reclock( gp, size, offset,
    lckdat, cmd, retray_fcn, retry_id, lock_fcn,
    rele_fcn)
struct gnode *gp;
offset_t size;
offset_t offset;
struct eflock *lckdat;
int cmd;
int (*retry_fcn)();
ulong *retry_id;
int (*lock_fcn)();
int (*rele_fcn)();
```

#### **Parameters**

gp Points to the gnode that represents the file to lock.size Identifies the current size of the file in bytes.

offset Specifies the current file offset. The system uses the offset parameter to establish where the lock

region is to begin.

*lckdat* Points to an **eflock** structure that describes the lock operation to perform.

cmd

Defines the type of operation the kernel service performs. This parameter is a bit mask consisting of the following bits:

#### **SETFLCK**

If set, the system sets or clears a lock. If not set, the lock information is returned.

#### SLPFLCK

If the lock cannot be granted immediately, wait for it. This is only valid when SETFLCK flag is set.

#### INOFLCK

The caller is holding a lock on the object referred to by the gnode. The common\_reclock kernel service calls the release function before sleeping, and the lock function on return from sleep.

When the cmd parameter is set to SLPFLCK, it indicates that if the lock cannot be granted immediately, the service should wait for it. If the retry\_fcn parameter contains a valid pointer, the common\_reclock kernel service does not sleep, regardless of the SLPFLCK flag.

retry\_fcn

Points to a retry function. This function is called when the lock is retried. The retry function is not used if the lock is granted immediately. When the requested lock is blocked by an existing lock, a sleeping lock is established with the retry function address stored in it. The common\_reclock kernel service then returns a correlating ID (see the retry\_id parameter) to the calling routine, along with an exit value of EAGAIN. When the sleeping lock is awakened, the retry function is called with the correlating ID as its ID argument.

If this argument is not NULL, then the common\_ reclock kernel service does not sleep, regardless of the SLPFLCK command flag.

retry\_id

Points to location to store the correlating ID. This ID is used to correlate a retry operation with a specific lock or set of locks. This parameter is used only in conjunction with retry function. The value stored in this location is an opaque value. The caller should not use this value for any purpose other than lock correlation.

lock\_fcn

Points to a lock function. This function is invoked by the common reclock kernel service to lock a data structure used by the caller. Typically this is the data structure containing the gnode to lock. This function is necessary to serialize access to the object to lock. When the common\_reclock kernel service invokes the lock function, it is passed the private data pointer from the gnode as its only argument.

rele fcn

Points to a release function. This function releases the lock acquired with the lock function. When the release function is invoked, it is passed the private data pointer from the gnode as its only argument.

# **Description**

The common\_reclock routine implements a generic interface to the record-locking functions. This service allows distributed file systems to use byte-range locking. The kernel service does the following when a requested lock is blocked by an existing lock:

- Establishes a sleeping lock with the retry function in the **lock** structure. The address of the retry function is specified by the *retry\_fcn* parameter.
- Returns a correlating ID value to the caller along with an exit value of EAGAIN. The ID is stored in the retry id parameter.
- Calls the retry function when the sleeping lock is later awakened, the retry function is called with the retry\_id parameter as its argument.

Note: Before a call to the common\_ reclock subroutine, the eflock structure must be completely filled in. The *lckdat* parameter points to the **eflock** structure.

The caller can hold a serialization lock on the data object pointed to by the gnode. However, if the caller expects to sleep for a blocking-file lock and is holding the object lock, the caller must specify a lock function with the lock\_fcn parameter and a release function with the rele\_fcn parameter.

The lock is described by a **eflock** structure. This structure is identified by the *lckdat* parameter. If a read lock (**F\_RDLCK**) or write lock (**F\_WRLCK**) is set with a length of 0, the entire file is locked. Similarly, if unlock (**F\_UNLCK**) is set starting at 0 for 0 length, all locks on this file are unlocked. This method is how locks are removed when a file is closed.

To allow the **common\_reclock** kernel service to update the per-gnode lock list, the service takes a **GN\_RECLK\_LOCK** lock during processing.

#### **Execution Environment**

The **common\_reclock** kernel service can be called from the process environment only.

#### **Return Values**

0 Indicates successful completion.

**EAGAIN** Indicates a lock cannot be granted because of a blocking lock and the caller did not request that the

operation sleep.

**ERRNO** Indicates an error. Refer to the **fcntl** system call for the list of possible values.

#### **Related Information**

The **fcntl** subroutine.

The flock.h file.

## compare\_and\_swap Kernel Services

## **Purpose**

Conditionally updates or returns a variable atomically.

# **Syntax**

```
#include <sys/atomic_op.h>
boolean_t compare_and_swap ( addr,  old_val_addr,  new_val)
atomic_p addr;
int * old_val_addr;
int new_val;

boolean_t compare_and_swaplp ( addr,  old_val_addr,  new_val)
atomic_l addr;
long * old_val_addr;
long new val;
```

#### **Parameters**

addr Specifies the address of the variable.

old\_val\_addr Specifies the address of the old value to be checked against (and conditionally updated with)

the value of the variable.

new\_val Specifies the new value to be conditionally assigned to the variable.

## **Description**

The compare and swap kernel services performs an atomic (uninterruptible) operation which compares the contents of a variable with a stored old value; if equal, a new value is stored in the variable, and TRUE is returned, otherwise the old value is set to the current value of the variable, and FALSE is returned.

The compare and swap kernel service operates on a single word (32 bit) variable while the compare\_and\_swaplp kernel service operates on a double word (64 bit) variable.

The compare\_and\_swap kernel services are particularly useful in operations on singly linked lists, where a list pointer must not be updated if it has been changed by another thread since it was read.

#### Note:

- The single word variable passed to the compare and swap kernel service must be aligned on a full word (32 bit) boundary.
- The double word variable passed to the compare and swaplp kernel service must be aligned on a double word (64 bit) boundary.

### **Execution Environment**

The compare\_and\_swap kernel services can be called from either the process or interrupt environment.

### **Return Values**

**TRUE** Indicates that the variable was equal to the old value, and has been set to the new value.

**FALSE** Indicates that the variable was not equal to the old value, and that its current value has been returned in the location where the old value was stored.

#### **Related Information**

The fetch and add kernel service, fetch and and kernel service, fetch and or kernel service.

Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

# coprocessor\_user\_register Kernel Service

# **Purpose**

Registers the current process as a coprocessor user.

# **Syntax**

```
#include <sys/coprocessor.h>
kerrno_t coprocessor_user_register ( int coprocessor type, unsigned int * phandle )
```

#### **Parameters**

coprocessor\_type Numeric value in the [0..63] range

phandle Pointer to an unsigned 32 bit integer where a handle identifying this process is returned.

# **Description**

This kernel service allows a kernel extension to register the current process as a user of the coprocessor type passed as the first argument. When successful, the service sets up values in the process context that allow the current process to access coprocessors of the specified type in user mode.

### **Execution Environment**

This kernel service can be called in the process environment only.

#### **Return Values**

When the call is successful, the kernel service returns a value of zero. Otherwise, a negative value is returned to indicate an error.

### **Error Values**

Possible errors are:

- Coprocessors not supported (supported only on Power 7 and newer processors)
- Invalid coprocessor type (must be in the range 0-63).
- · Bad address passed as the second argument.
- The current process is already registered for this coprocessor type.
- · The service is being called in interrupt context.
- The service could not allocate a value for the handle.

### **Related Information**

coprocessor user unregister

## coprocessor\_user\_unregister Kernel Service

## **Purpose**

Unregisters the current process as a coprocessor user.

## **Syntax**

```
#include <sys/coprocessor.h>
kerrno_t coprocessor_user_unregister ( int coprocessor_type )
```

### **Parameters**

coprocessor\_type Numeric value in the range [0..63] which identifies a coprocessor type.

# **Description**

This kernel service allows a kernel extension to unregister the current process that was previously registered as a coprocessor user. When successful, further accesses by the process to the coprocessor type passed as an argument in user mode will fail with a privileged operation exception.

### **Execution Environment**

This kernel service can be called in the process environment only.

#### **Return Values**

When the call is successful, the kernel service returns a value of zero. Otherwise, a negative value is returned to indicate an error.

### **Error Values**

Possible errors are:

- Coprocessors not supported (supported only on Power 7 and newer processors).
- Invalid coprocessor type (must be in the range 0-63).

- · The current process is not registered for this coprocessor type.
- The service is being called in interrupt context.

### **Related Information**

coprocessor\_user\_register

## copyin Kernel Service

## **Purpose**

Copies data between user and kernel memory.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int copyin ( uaddr, kaddr, count)
char *uaddr:
char *kaddr;
int count;
```

#### **Parameters**

Specifies the address of user data. uaddr kaddr Specifies the address of kernel data. Specifies the number of bytes to copy. count

# **Description**

The copyin kernel service copies the specified number of bytes from user memory to kernel memory. This service is provided so that system calls and device driver top half routines can safely access user data. The **copyin** service ensures that the user has the appropriate authority to access the data. It also provides recovery from paging I/O errors that would otherwise cause the system to crash.

The **copyin** service should be called only while executing in kernel mode in the user process.

### **Execution Environment**

The **copyin** kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

**EFAULT** Indicates that the user has insufficient authority to access the data, or the address

specified in the *uaddr* parameter is not valid.

EIO Indicates that a permanent I/O error occurred while referencing data. **ENOMEM** Indicates insufficient memory for the required paging operation.

**ENOSPC** Indicates insufficient file system or paging space.

### **Related Information**

Accessing User-Mode Data While in Kernel Mode and Memory Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

The **copyinstr** kernel service, **copyout** kernel service.

## copyinstr Kernel Service

## **Purpose**

Copies a character string (including the terminating null character) from user to kernel space.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/uio.h>

On the 32-bit kernel, the syntax for the copyinstr Kernel Service is:
int copyinstr (from, to, max, actual)
caddr_t from;
caddr_t to;
uint max;
uint *actual;

On the 64-bit kernel, the syntax for the copyinstr subroutine is:
int copyinstr (from, to, max, actual)
void *from;
void *to;
size_t max;
size_t *actual;
```

#### **Parameters**

from Specifies the address of the character string to copy.

to Specifies the address to which the character string is to be copied.

max Specifies the number of characters to be copied.

actual Specifies a parameter, passed by reference, that is updated by the copyinstr service with the actual

number of characters copied.

# **Description**

The **copyinstr** kernel service permits a user to copy character data from one location to another. The source location must be in user space or can be in kernel space if the caller is a kernel process. The destination is in kernel space.

#### **Execution Environment**

The **copyinstr** kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful operation.

**E2BIG** Indicates insufficient space to complete the copy.

**EIO** Indicates that a permanent I/O error occurred while referencing data.

**ENOSPC** Indicates insufficient file system or paging space.

**EFAULT** Indicates that the user has insufficient authority to access the data or the address specified in the *uaddr* 

parameter is not valid.

### **Related Information**

Accessing User-Mode Data While in Kernel Mode and Memory Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## copyout Kernel Service

## **Purpose**

Copies data between user and kernel memory.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int copyout ( kaddr, uaddr, count)
char *kaddr;
char *uaddr:
int count;
```

### **Parameters**

kaddr Specifies the address of kernel data. uaddr Specifies the address of user data. count Specifies the number of bytes to copy.

## **Description**

The **copyout** service copies the specified number of bytes from kernel memory to user memory. It is provided so that system calls and device driver top half routines can safely access user data. The copyout service ensures that the user has the appropriate authority to access the data. This service also provides recovery from paging I/O errors that would otherwise cause the system to crash.

The **copyout** service should be called only while executing in kernel mode in the user process.

### **Execution Environment**

The copyout kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

**EFAULT** Indicates that the user has insufficient authority to access the data or the address

specified in the *uaddr* parameter is not valid.

EIO Indicates that a permanent I/O error occurred while referencing data. **ENOMEM** Indicates insufficient memory for the required paging operation.

**ENOSPC** Indicates insufficient file system or paging space.

#### **Related Information**

The copyin kernel service, copyinstr kernel service.

Accessing User-Mode Data While in Kernel Mode and Memory Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# crcopy Kernel Service

## **Purpose**

Copies a credentials structure to a new one and frees the old one.

## **Syntax**

```
#include <sys/cred.h>
struct ucred * crcopy ( cr)
struct ucred * cr;
```

### **Parameter**

cr

Pointer to the credentials structure that is to be copied and then freed.

## **Description**

The **crcopy** kernel service allocates a new credentials structure that is initialized from the contents of the *cr* parameter. The reference to *cr* is then freed and a pointer to the new structure returned to the caller.

**Note:** The *cr* parameter must have been obtained by an earlier call to the **crcopy** kernel service, **crdup** kernel service, **crget** kernel service, or the **crref** kernel service.

## **Execution Environment**

The **crcopy** kernel service can be called from the process environment only.

### **Return Values**

Nonzero value A pointer to a newly allocated and initialized credentials structure.

**Zero value**An error occurred when the kernel service was attempting to allocate pinned

memory for the credentials structure.

#### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# crdup Kernel Service

# **Purpose**

Copies a credentials structure to a new one.

# **Syntax**

#include <sys/cred.h>

```
struct ucred * crdup ( cr)
struct ucred * cr;
```

### **Parameter**

cr

Pointer to the credentials structure that is to be copied.

## **Description**

The **crdup** kernel service allocates a new credentials structure that is initialized from the contents of the *cr* parameter.

### **Execution Environment**

The **crdup** kernel service can be called from the process environment only.

### **Return Values**

A pointer to a newly allocated and initialized credentials structure. Nonzero value

Zero value An error occurred when the kernel service was attempting to allocate pinned memory

for the credentials structure.

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## creatp Kernel Service

# **Purpose**

Creates a new kernel process.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> pid t creatp()

# **Description**

The creatp kernel service creates a kernel process. It also allocates and initializes a process block for the new process. Initialization involves these three tasks:

- Assigning an identifier to the kernel process.
- · Setting the process state to idle.
- · Initializing its parent, child, and sibling relationships.

"Using Kernel Processes" in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts has a more detailed discussion of how the creatp kernel service creates and initializes kernel processes.

The process calling the creatp service must subsequently call the initp kernel service to complete the process initialization. The initp service also makes the newly created process runnable.

### **Execution Environment**

The **creatp** kernel service can be called from the process environment only.

#### **Return Values**

-1 Indicates an error.

Upon successful completion, the creatp kernel service returns the process identifier for the new kernel process.

### **Related Information**

The initp kernel service.

CRED\_GETEUID, CRED\_GETRUID, CRED\_GETSUID, CRED\_GETLUID, CRED GETEGID, CRED GETRGID, CRED GETSGID and **CRED GETNGRPS Macros** 

## Purpose

Credentials structure field accessing macros.

# **Syntax**

```
#include <sys/cred.h>
uid t CRED GETEUID ( crp )
uid t CRED GETRUID ( crp )
uid t CRED GETSUID ( crp )
uid_t CRED_GETLUID ( crp )
gid_t CRED_GETEGID ( crp )
gid_t CRED_GETRGID ( crp )
gid t CRED GETSGID ( crp )
int CRED GETNGRPS ( crp )
```

#### **Parameter**

crp

Pointer to a credentials structure

# **Description**

These macros provide a means for accessing the user and group identifier fields within a credentials structure. The fields within a ucred structure should not be accessed directly as the field names and their locations are subject to change.

The CRED GETEUID macro returns the effective user ID field from the credentials structure referenced by crp.

The CRED\_GETRUID macro returns the real user ID field from the credentials structure referenced by crp.

The CRED\_GETSUID macro returns the saved user ID field from the credentials structure referenced by

The CRED GETLUID macro returns the login user ID field from the credentials structure referenced by crp.

The CRED\_GETEUID macro returns the effective group ID field from the credentials structure referenced by crp.

The CRED\_GETRUID macro returns the real group ID field from the credentials structure referenced by

The CRED\_GETSUID macro returns the saved group ID field from the credentials structure referenced by crp.

The CRED GETNGRPS macro returns the number of concurrent group ID values stored within the credentials structure referenced by crp.

These macros are defined in the system header file <sys/cred.h>.

#### **Execution Environment**

The credentials macros called with any valid credentials pointer.

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## crexport Kernel Service

## **Purpose**

Copies an internal format credentials structure to an external format credentials structure.

# **Syntax**

```
#include <sys/cred.h>
void crexport (src, dst)
struct ucred * src;
struct ucred ext * dst;
```

#### **Parameter**

Pointer to the internal credentials structure. src Pointer to the external credentials structure. dst

# **Description**

The **crexport** kernel service copies from the internal credentials structure referenced by *src* into the external credentials structure referenced by dst. The external credentials structure is guaranteed to be compatible between releases. Fields within a ucred structure must not be referenced directly as the field names and locations within that structure are subject to change.

#### **Execution Environment**

The **crexport** kernel service can be called from the process environment only.

#### **Return Values**

This kernel service does not have a return value.

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## crfree Kernel Service

## **Purpose**

Releases a reference count on a credentials structure.

## **Syntax**

```
#include <sys/cred.h>
void crfree ( cr)
struct ucred * cr;
```

### **Parameter**

cr

Pointer to the credentials structure that is to have a reference freed.

# **Description**

The **crfree** kernel service deallocates a reference to a credentials structure. The credentials structure is deallocated when no references remain.

**Note:** The *cr* parameter must have been obtained by an earlier call to the **crcopy** kernel service, **crdup** kernel service, **crget** kernel service, or the **crref** kernel service.

## **Execution Environment**

The **crfree** kernel service can be called from the process environment only.

#### Return Values

No value is returned by this kernel service.

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# crget Kernel Service

# **Purpose**

Allocates a new, uninitialized credentials structure to a new one and frees the old one.

# **Syntax**

```
#include <sys/cred.h>
struct ucred * crget ( void )
```

### **Parameter**

This kernel service does not require any parameters.

## **Description**

The crget kernel service allocates a new credentials structure. The structure is initialized to all zero values, and the reference count is set to 1.

### **Execution Environment**

The **crget** kernel service can be called from the process environment only.

### Return Values

Nonzero value A pointer to a newly allocated and initialized credentials structure.

Zero value An error occurred when the kernel service was attempting to allocate pinned

memory for the credentials structure.

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## crhold Kernel Service

## **Purpose**

Increments the reference count for a credentials structure.

# **Syntax**

```
#include <sys/cred.h>
```

```
void crhold (cr)
struct ucred * cr;
```

### **Parameter**

Pointer to the credentials structure that will have its reference count incremented.

# **Description**

The **crhold** kernel service increments the reference count of a credentials structure.

Note: Reference counts that are incremented with the crhold kernel service must be decremented with the crfree kernel service.

#### **Execution Environment**

The **crhold** kernel service can be called from the process environment only.

#### **Return Values**

No value is returned by this kernel service.

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## crref Kernel Service

## **Purpose**

Increments the reference count for the current credentials structure.

## **Syntax**

```
#include <sys/cred.h>
struct ucred * crref ( void )
```

### **Parameter**

This kernel service does not require any parameters.

## **Description**

The **crref** kernel service increments the reference count of the current credentials structure and returns a pointer to the current credentials structure to the invoker.

**Note:** References that are allocated with the **crref** kernel service must be released with the **crfree** kernel service.

## **Execution Environment**

The **crref** kernel service can be called from the process environment only.

### **Return Values**

Nonzero value

A pointer to the current credentials structure.

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## crset Kernel Service

## **Purpose**

Sets the current security credentials.

# **Syntax**

```
#include <sys/cred.h>
void crset ( cr)
struct ucred * cr;
```

### **Parameter**

cr

Pointer to the credentials structure that will become the new, current security credentials.

## **Description**

The **crset** kernel service replaces the current security credentials with the supplied value. The existing structure will be deallocated.

Note: The cr parameter must have been obtained by an earlier call to the crcopy kernel service, crdup kernel service, crget kernel service, or the crref kernel service.

### **Execution Environment**

The **crset** kernel service can be called from the process environment only.

### **Return Values**

No value is returned by this kernel service.

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## curtime Kernel Service

## **Purpose**

Reads the current time into a time structure.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/time.h>
void curtime ( timestruct)
struct timestruc t *timestruct;
```

### **Parameter**

timestruct

Points to a timestruc t time structure defined in the /usr/include/sys/time.h file. The curtime kernel service updates the fields in this structure with the current time.

# **Description**

The curtime kernel service reads the current time into a time structure defined in the /usr/include/sys/time.h file. This service updates the tv sec and tv nsec fields in the time structure, pointed to by the timestruct parameter, from the hardware real-time clock. The kernel also maintains and updates a memory-mapped time tod structure. This structure is updated with each clock tick.

The kernel also maintains two other in-memory time values: the **lbolt** and **time** values. The three in-memory time values that the kernel maintains (the tod, lbolt, and time values) are available to kernel extensions. The Ibolt in-memory time value is the number of timer ticks that have occurred since the system was booted. This value is updated once per timer tick. The time in-memory time value is the number of seconds since Epoch. The kernel updates the value once per second.

Note: POSIX 1003.1 defines "seconds since Epoch" as a "value interpreted as the number of seconds between a specified time and the Epoch". It further specifies that a "Coordinated Universal Time name specified in terms of seconds (tm\_sec), minutes (tm\_min), hours (tm\_hour), and days since January 1 of the year (tm\_yday), and calendar year minus 1900 (tm\_year) is related to a time represented as seconds since the Epoch, according to the following expression: tm\_sec + tm\_min \* 60 tm hour\*3600 + tm yday \* 86400 + (tm year - 70) \* 31536000 ((tm year - 69) / 4) \* 86400 if the year is greater than or equal to 1970, otherwise it is undefined."

The **curtime** kernel service does not page-fault if a pinned stack and input time structure are used. Also, accessing the **Ibolt**, time, and tod in-memory time values does not cause a page fault since they are in pinned memory.

### **Execution Environment**

The curtime kernel service can be called from either the process or interrupt environment.

The tod, time, and lbolt memory-mapped time values can also be read from the process or interrupt handler environment. The timestruct parameter and stack must be pinned when the curtime service is called in an interrupt handler environment.

## **Return Values**

The **curtime** kernel service has no return values.

### **Related Information**

Timer and Time-of-Day Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## d\_align Kernel Service

# **Purpose**

Provides needed information to align a buffer with a processor cache line.

# Library

Kernel Extension Runtime Routines Library (libsys.a)

# **Syntax**

int d align()

# **Description**

To maintain cache consistency with system memory, buffers must be aligned. The d align kernel service helps provide that function by returning the maximum processor cache-line size. The cache-line size is returned in log2 form.

#### **Execution Environment**

The **d** align service can be called from either the process or interrupt environment.

#### **Related Information**

The **d\_cflush** kernel service, **d\_roundup** kernel service.

Understanding Direct Memory Access (DMA) Transfer in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## d\_alloc\_dmamem Kernel Service

## **Purpose**

Allocates an area of "dma-able" memory.

## **Syntax**

void \*

d alloc dmamem(d handle t device handle, size t size, int align)

## Description

Exported, documented kernel service supported on PCI-based systems only. The d alloc dmamem kernel service allocates an area of "dma-able" memory which satisfies the constraints associated with a DMA handle, specified via the device\_handle parameter. The constraints (such as need for contiguous physical pages or need for 32-bit physical address) are intended to guarantee that a given adapter will be able to access the physical pages associated with the allocated memory. A driver associates such constraints with a dma handle via the *flags* parameter on its **d map init** call.

The area to be allocated is the number of bytes in length specified by the size parameter, and is aligned on the byte boundary specified by the align parameter. The align parameter is actually the log base 2 of the desired address boundary. For example, an align value of 12 requests that the allocated area be aligned on a 4096 byte boundary.

**d\_alloc\_dmamem** is appropriate to be used for long-term mappings. Depending on the system configuration and the constraints encoded in the device\_handle, the underlying storage will come from either the real\_heap (rmalloc service) or pinned\_heap (xmalloc service).

#### Notes:

- 1. The d\_free\_dmamem service should be called to free allocation from a previous d\_alloc\_dmamem call.
- 2. The d\_alloc\_dmamem kernel service can be called from the process environment only.

#### **Parameters**

device handle Indicates the dma handle.

Specifies alignment characteristics. align size\_t size Specifies number of bytes to allocate.

### **Return Values**

area NULL Requested memory could not be allocated.

#### **Related Information**

The d\_free\_dmamem kernel service, d\_map\_init kernel service, rmalloc kernel service, xmalloc kernel service.

## d\_cflush Kernel Service

## **Purpose**

Flushes the processor and I/O channel controller (IOCC) data caches when mapping bus device DMA with the long-term **DMA\_WRITE\_ONLY** option.

## **Syntax**

```
int d_cflush (channel_id, baddr, count, daddr)
int channel_id;
caddr_t baddr;
size_t count;
caddr t daddr;
```

### **Parameters**

channel\_id Specifies the DMA channel ID returned by the d\_init kernel service.

baddr Designates the address of the memory buffer.

count Specifies the length of the memory buffer transfer in bytes.

daddr Designates the address of the device corresponding to the transfer.

## **Description**

The **d\_cflush** kernel service should be called after data has been modified in a buffer that will undergo direct memory access (DMA) processing. Through DMA processing, this data is sent to a device where the **d\_master** kernel service with the **DMA\_WRITE\_ONLY** option has already mapped the buffer for device DMA. The **d\_cflush** kernel service is not required if the **DMA\_WRITE\_ONLY** option is not used or if the buffer is mapped before each DMA operation by calling the **d\_master** kernel service.

The **d\_cflush** kernel service flushes the processor cache for the involved cache lines and invalidates any previously retrieved data that may be in the IOCC buffers for the designated channel. This most frequently occurs when using long-term buffer mapping for DMA support to or from a device.

## **Long-Term DMA Buffer Mapping**

The long-term DMA buffer mapping approach is frequently used when a pool of buffers is defined for sending commands and obtaining responses from an adapter using bus master DMA. This approach is also used frequently in the communications field where buffers can come from a common pool such as the **mbuf** pool or a pool used for protocol headers.

When using a fixed pool of buffers, the **d\_master** kernel service is used only once to map the pool's address and range. The device driver then modifies the data in the buffers. It must also flush the data from the processor and invalidate the IOCC data cache involved in transfers with the device. The IOCC cache must be invalidated because the data in the IOCC data cache may be stale due to the last DMA operation to or from the buffer area that has just been modified for the next operation.

The **d\_cflush** kernel service permits the flushing of the processor cache and making the required IOCC cache not valid. The device driver should use this service after modifying the data in the buffer and before sending the command to the device to start the DMA operation.

Once DMA processing has been completed, the device driver should call the **d\_complete** service to check for errors and ensure that any data read from the device has been flushed to memory.

**Note:** The **d\_cflush** kernel service is not supported on the 64-bit kernel.

### **Execution Environment**

The **d\_cflush** kernel service can be called from either the process or interrupt environment.

### **Return Values**

Indicates that the transfer was successfully completed.

**EINVAL** Indicates the presence of an invalid parameter.

### **Related Information**

I/O Kernel Services and Understanding Direct Memory Access (DMA) Transfer in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## delay Kernel Service

## **Purpose**

Suspends the calling process for the specified number of timer ticks.

## **Syntax**

#include <sys/types.h> #include <sys/errno.h>

void delay (ticks) int ticks;

### **Parameter**

ticks

Specifies the number of timer ticks that must occur before the process is reactivated. Many timer ticks can occur per second.

# **Description**

The **delay** kernel service suspends the calling process for the number of timer ticks specified by the ticks parameter.

The HZ value in the /usr/include/sys/m\_param.h file can be used to determine the number of ticks per second.

#### **Execution Environment**

The **delay** kernel service can be called from the process environment only.

#### **Return Values**

The delay service has no return values.

#### **Related Information**

Timer and Time-of-Day Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## del\_domain\_af Kernel Service

## **Purpose**

Deletes an address family from the Address Family domain switch table.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/domain.h>

int
del_domain_af ( domain)
struct domain *domain;
```

### **Parameter**

domain Specifies the address family.

## **Description**

The **del\_domain\_af** kernel service deletes the address family specified by the *domain* parameter from the Address Family domain switch table.

### **Execution Environment**

The del\_domain\_af kernel service can be called from either the process or interrupt environment.

## **Return Value**

**EINVAL** Indicates that the specified address is not found in the Address Family domain switch table.

# **Example**

To delete an address family from the Address Family domain switch table, invoke the **del\_domain\_af** kernel service as follows:

```
del domain af(&inetdomain);
```

In this example, the family to be deleted is inetdomain.

### **Related Information**

The add\_domain\_af kernel service.

Network Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# del\_input\_type Kernel Service

# **Purpose**

Deletes an input type from the Network Input table.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>

int del_input_type
( type)
u short type;
```

### **Parameter**

type Specifies which type of protocol the packet contains. This parameter is a field in a packet.

# **Description**

The **del\_input\_type** kernel service deletes an input type from the Network Input table to disable the reception of the specified packet type.

### **Execution Environment**

The del\_input\_type kernel service can be called from either the process or interrupt environment.

### **Return Values**

Indicates that the type was successfully deleted.

**ENOENT** Indicates that the **del\_input\_type** service could not find the type in the Network Input table.

## **Examples**

To delete an input type from the Network Input table, invoke the del\_input\_type kernel service as follows:

```
del input type(ETHERTYPE IP);
```

In this example, ETHERTYPE\_IP specifies that Ethernet IP packets should no longer be processed.

To delete an input type from the Network Input table, invoke the del\_input\_type kernel service as follows:

```
del input type(ETHERTYPE ARP);
```

In this example, ETHERTYPE ARP specifies that Ethernet ARP packets should no longer be processed.

### **Related Information**

The add\_input\_type kernel service, find\_input\_type kernel service.

Network Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## del\_netisr Kernel Service

# **Purpose**

Deletes a network software interrupt service routine from the Network Interrupt table.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/netisr.h>

int del_netisr ( soft_intr_level)
u_short soft intr level;
```

## **Parameter**

soft\_intr\_level

Specifies the software interrupt level to delete. This parameter must be greater than or equal to 0 and less than **NETISR\_MAX**. Refer to **netisr.h** for the range of values of *soft\_intr\_level* that are already in use. Also, other kernel extensions that are not AIX® and that use network ISRs currently running on the system can make use of additional values not mentioned in **netisr.h**.

## **Description**

The **del\_netisr** kernel service deletes the network software interrupt service routine specified by the *soft\_intr\_level* parameter from the Network Software Interrupt table.

### **Execution Environment**

The **del\_netisr** kernel service can be called from either the process or interrupt environment.

### **Return Values**

Indicates that the software interrupt service was successfully deleted.

**ENOENT** Indicates that the software interrupt service was not found in the Network Software Interrupt table.

# **Example**

To delete a software interrupt service from the Network Software Interrupt table, invoke the kernel service as follows:

```
del netisr(NETISR IP);
```

In this example, the software interrupt routine to be deleted is NETISR IP.

## **Related Information**

The add netisr kernel service.

Network Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# del\_netopt Macro

# **Purpose**

Deletes a network option structure from the list of network options.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/netopt.h>
```

```
del_netopt ( option name symbol)
option name symbol;
```

### **Parameter**

option\_name\_symbol

Specifies the symbol name used to construct the netopt structure and default

names.

## **Description**

The del\_netopt macro deletes a network option from the linked list of network options. After the del\_netopt service is called, the option is no longer available to the no command.

## **Execution Environment**

The del\_netopt macro can be called from either the process or interrupt environment.

### Return Values

The del netopt macro has no return values.

### **Related Information**

The **no** command.

The add netopt macro.

Network Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# detach Device Queue Management Routine

# **Purpose**

Provides a means for performing device-specific processing when the detchq kernel service is called.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/deviceq.h>
int detach ( dev parms, path id)
caddr t dev parms;
cba id path id;
```

### **Parameters**

Passed to creatd service when the detach routine is defined. dev\_parms path\_id Specifies the path identifier for the queue that is being detached from.

# **Description**

The detach routine is part of the Device Queue Management kernel extension. Each device queue can have a detach routine. This routine is optional and must be specified when the device queue is defined with the creatd service. The detchq service calls the detach routine each time a path to the device queue is removed.

To ensure that the **detach** routine is not called while a queue element from this client is still in the device queue, the kernel puts a detach control queue element at the end of the device queue. The server knows by convention that a detach control queue element signifies completion of all pending queue elements for that path. The kernel calls the **detach** routine after the detach control queue element is processed.

The **detach** routine executes under the process under which the **detchg** service is called. The kernel does not serialize the execution of this service with the execution of any of the other server routines.

### **Execution Environment**

The **detach** routine can be called from the process environment only.

### **Return Values**

RC GOOD Indicates successful completion.

A return value other than **RC GOOD** indicates an irrecoverable condition causing system failure.

## devdump Kernel Service

## **Purpose**

Calls a device driver dump-to-device routine.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int devdump
(devno, uiop, cmd, arg, chan, ext)
dev t devno;
struct uio * uiop;
int cmd, arg, ext;
```

#### **Parameters**

devno Specifies the major and minor device numbers. uiop Points to the **uio** structure containing write parameters. Specifies which dump command to perform. cmd Specifies a parameter or address to a parameter block for the specified command. arg Specifies the channel ID. chan Specifies the extended system call parameter. ext

# **Description**

The kernel or kernel extension calls the **devdump** kernel service to initiate a memory dump to a device when writing dump data and then to terminate the dump to the target device.

The **devdump** service calls the device driver's **dddump** routine, which is found in the device switch table for the device driver associated with the specified device number. If the device number (specified by the devno parameter) is not valid or if the associated device driver does not have a **dddump** routine, an **ENODEV** return value is returned.

If the device number is valid and the specified device driver has a dddump routine, the routine is called.

If the device driver's **dddump** routine is successfully called, the return value for the **devdump** service is set to the return value provided by the device's **dddump** routine.

### **Execution Environment**

The **devdump** kernel service can be called in either the process or interrupt environment, as described under the conditions described in the **dddump** routine.

### **Return Values**

Indicates a successful operation.

**ENODEV** Indicates that the device number is not valid or that no **dddump** routine is registered for this device.

The **dddump** device driver routine provides other return values.

### **Related Information**

The **dddump** device driver entry point.

Kernel Extension and Device Driver Management Kernel Services and How Device Drivers are Accessed in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## devstrat Kernel Service

## **Purpose**

Calls a block device driver's strategy routine.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int devstrat ( bp)
struct buf *bp;
```

### **Parameter**

Points to the **buf** structure specifying the block transfer parameters.

# **Description**

The kernel or kernel extension calls the **devstrat** kernel service to request a block data transfer to or from the device with the specified device number. This device number is found in the buf structure. The devstrat service can only be used for the block class of device drivers.

The devstrat service calls the device driver's ddstrategy routine. This routine is found in the device switch table for the device driver associated with the specified device number found in the b dev field. The b dev field is found in the **buf** structure pointed to by the bp parameter. The caller of the **devstrat** service must have an iodone routine specified in the b iodone field of the buf structure. Following the return from the device driver's ddstrategy routine, the devstrat service returns without waiting for the I/O to be performed.

On multiprocessor systems, all **iodone** routines run by default on the first processor started when the system was booted. This ensures compatibility with uniprocessor device drivers. If the iodone routine has been designed to be multiprocessor-safe, set the B\_MPSAFE flag in the b flags field of the buf structure passed to the **devstrat** kernel service. The **iodone** routine will then run on any available processor.

If the device major number is not valid or the specified device is not a block device driver, the devstrat service returns the ENODEV return code. If the device number is valid, the device driver's ddstrategy routine is called with the pointer to the **buf** structure (specified by the *bp* parameter).

### **Execution Environment**

The **devstrat** kernel service can be called from either the process or interrupt environment.

Note: The devstrat kernel service can be called in the interrupt environment only if its priority level is **INTIODONE** or lower.

### **Return Values**

Indicates a successful operation.

**ENODEV** 

Indicates that the device number is not valid or that no **ddstrategy** routine registered. This value is also returned when the specified device is not a block device driver. If this error occurs, the devstrat service can cause a page fault.

### **Related Information**

The iodone kernel service.

The **ddstategy** routine.

The **buf** structure.

Kernel Extension and Device Driver Management Kernel Services and How Device Drivers are Accessed in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### devswadd Kernel Service

## Purpose

Adds a device entry to the device switch table.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/device.h>
int devswadd ( devno, dswptr)
dev t devno;
struct devsw *dswptr;
```

### **Parameters**

dswptr

Specifies the major and minor device numbers to be associated with the specified entry in the device devno

Points to the device switch structure to be added to the device switch table.

## **Description**

The **devswadd** kernel service is typically called by a device driver's **ddconfig** routine to add or replace the device driver's entry points in the device switch table. The device switch table is a table of device switch (devsw) structures indexed by the device driver's major device number. This table of structures is used by the device driver interface services in the kernel to facilitate calling device driver routines.

The major device number portion of the devno parameter is used to specify the index in the device switch table where the devswadd service must place the specified device switch entry. Before this service copies the device switch structure into the device switch table, it checks the existing entry to determine if any opened device is using it. If an opened device is currently occupying the entry to be replaced, the devswadd service does not perform the update. Instead, it returns an EEXIST error value. If the update is successful, it returns a value of 0.

Entry points in the device switch structure that are not supported by the device driver must be handled in one of two ways. If a call to an unsupported entry point should result in the return of an error code, then the entry point must be set to the **nodev** routine in the structure. As a result, any call to this entry point automatically invokes the nodev routine, which returns an ENODEV error code. The kernel provides the nodev routine.

Otherwise, a call to an unsupported entry point should be treated as a no-operation function. Then the corresponding entry point should be set to the nulldev routine. The nulldev routine, which is also provided by the kernel, performs no operation if called and returns a 0 return code.

On multiprocessor systems, all device driver routines run by default on the first processor started when the system was booted. This ensures compatibility with uniprocessor device drivers. If the device driver being added has been designed to be multiprocessor-safe, set the DEV MPSAFE flag in the d opts field of the devsw structure passed to the devswadd kernel service. The device driver routines will then run on any available processor.

All other fields within the structure that are not used should be set to 0. Some fields in the structure are for kernel use; the devswadd service does not copy these fields into the device switch table. These fields are documented in the /usr/include/device.h file.

#### **Execution Environment**

The **devswadd** kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful operation.

**EEXIST** Indicates that the specified device switch entry is in use and cannot be replaced.

ENOMEM Indicates that the entry cannot be pinned due to insufficient real memory.

EINVAL Indicates that the major device number portion of the devno parameter exceeds the maximum permitted

number of device switch entries.

#### **Related Information**

The **devswchg** kernel service, **devswdel** kernel service, **devswgry** kernel service.

The **ddconfig** device driver entry point.

Kernel Extension and Device Driver Management Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## devswchg Kernel Service

## **Purpose**

Alters a device switch entry point in the device switch table.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/device.h>

int devswchg ( devno, type, newfunc, oldfunc);
dev_t devno;
int type;
int (*newfunc) ();
int (**oldfunc)();
```

### **Parameters**

devno

Specifies the major and minor device numbers of the device to be changed.

type

Specifies the device switch entry point to alter. The type parameter can have one of the following

values:

DSW\_BLOCK

Alters the **ddstrategy** entry point.

DSW\_CONFIG

Alters the ddconfig entry point.

DSW\_CREAD

Alters the **ddread** entry point.

**DSW CWRITE** 

Alters the **ddwrite** entry point.

DSW\_DUMP

Alters the **dddump** entry point.

DSW MPX

Alters the **ddmpx** entry point.

**DSW SELECT** 

Alters the **ddselect** entry point.

DSW\_TCPATH

Alters the ddrevoke entry point.

newfunc S

Specifies the new value for the device switch entry point.

oldfunc

Specifies that the old value of the device switch entry point be returned here.

# **Description**

The **devswchg** kernel service alters the value of a device switch entry point (function pointer) after a device switch table entry has been added by the **devswadd** kernel service. The device switch entry point specified by the *type* parameter is set to the value of the *newfunc* parameter. Its previous value is returned in the memory addressed by the *oldfunc* parameter. Only one device switch entry can be altered per call.

If the **devswchg** kernel service is unsuccessful, the value referenced by the *oldfunc* parameter is not defined.

### **Execution Environment**

The **devswchg** kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful operation.

EINVAL Indicates the Type command was not valid.

ENODEV Indicates the device switch entry specified by the devno parameter is not defined.

### **Related Information**

The devswadd kernel service.

List of Kernel Extension and Device Driver Management Kernel Services and How Device Drivers are Accessed in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### devswdel Kernel Service

## **Purpose**

Deletes a device driver entry from the device switch table.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/device.h>
int devswdel
( devno)
dev t devno;
```

### **Parameter**

Specifies the major and minor device numbers of the device to be deleted. devno

# **Description**

The **devswdel** kernel service is typically called by a device driver's **ddconfig** routine on termination to remove the device driver's entry points from the device switch table. The device switch table is a table of device switch (devsw) structures indexed by the device driver's major device number. The device driver interface services use this table of structures in the kernel to facilitate calling device driver routines.

The major device number portion of the devno parameter is used to specify the index into the device switch table for the entry to be removed. Before the device switch structure is removed, the existing entry is checked to determine if any opened device is using it.

If an opened device is currently occupying the entry to be removed, the devswdel service does not perform the update. Instead, it returns an EEXIST return code. If the removal is successful, a return code of 0 is set.

The devswdel service removes a device switch structure entry from the table by marking the entry as undefined and setting all of the entry point fields within the structure to a **nodev** value. As a result, any callers of the removed device driver return an ENODEV error code. If the specified entry is already marked undefined, the **devswdel** service returns an **ENODEV** error code.

### **Execution Environment**

The **devswdel** kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

EEXIST Indicates that the specified device switch entry is in use and cannot be removed.

ENODEV Indicates that the specified device switch entry is not defined.

EINVAL Indicates that the major device number portion of the devno parameter exceeds the maximum permitted

number of device switch entries.

## **Related Information**

The devswadd kernel service, devswchg kernel service, devswqry kernel service.

Kernel Extension and Device Driver Management Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# devswqry Kernel Service

## **Purpose**

Checks the status of a device switch entry in the device switch table.

## **Syntax**

```
#include <sys/types.h>
#include <svs/errno.h>
#include <sys/device.h>int devswqry ( devno, status, dsdptr)
dev t devno;
uint *status;
caddr t *dsdptr;
```

## **Parameters**

devno Specifies the major and minor device numbers of the device to be queried.

status Points to the status of the specified device entry in the device switch table. This parameter is passed by

Points to device-dependent information for the specified device entry in the device switch table. This dsdptr

parameter is passed by reference.

# **Description**

The devswqry kernel service returns the status of a specified device entry in the device switch table. The entry in the table to query is determined by the major portion of the device number specified in the devno parameter. The status of the entry is returned in the status parameter that is passed by reference on the call. If this pointer is null on entry to the **devswqry** service, then the status is not returned to the caller.

The devswqry service also returns the address of device-dependent information for the specified device entry in the device switch table. This address is taken from the d dsdptr field for the entry and returned in the dsdptr parameter, which is passed by reference. If this pointer is null on entry to the devswqry service, then the service does not return the address from the d dsdptr field to the caller.

### **Status Parameter Flags**

The status parameter comprises a set of flags that can indicate the following conditions:

DSW\_BLOCK Device switch entry is defined by a block device driver. This flag is set when the device

driver has a ddstrategy entry point.

DSW\_CONFIG Device driver in this device switch entry provides an entry point for configuration.

DSW\_CREAD Device driver in this device switch entry is providing a routine for character reads or raw

input. This flag is set when the device driver has a ddread entry point.

**DSW CWRITE** Device driver in this device switch entry is providing a routine for character writes or raw

output. This flag is set when the device driver has a ddwrite entry point.

DSW\_DEFINED Device switch entry is defined.

DSW\_DUMP Device driver defined by this device switch entry provides the capability to support one or

more of its devices as targets for a kernel dump. This flag is set when the device driver has

provided a **dddump** entry point.

DSW\_MPX Device switch entry is defined by a multiplexed device driver. This flag is set when the

device driver has a ddmpx entry point.

DSW\_OPENED Device switch entry is in use and the device has outstanding opens. This flag is set when

the device driver has at least one outstanding open.

Device driver in this device switch entry provides a routine for handling the select or poll DSW\_SELECT

subroutines. This flag is set when the device driver has provided a **ddselect** entry point.

**DSW TCPATH** Device driver in this device switch entry supports devices that are considered to be in the

trusted computing path and provide support for the revoke function. This flag is set when

the device driver has provided a **ddrevoke** entry point.

**DSW TTY** Device switch entry is in use by a tty device driver. This flag is set when the pointer to the

d\_ttys structure is not a null character.

DSW\_UNDEFINED Device switch entry is not defined.

The status parameter is set to the **DSW UNDEFINED** flag when a device switch entry is not in use. This is the case if either of the following are true:

· The entry has never been used. (No previous call to the devswadd service was made.)

· The entry has been used but was later deleted. (A call to the devswadd service was issued, followed by a call to the **devswdel** service.)

No other flags are set when the **DSW UNDEFINED** flag is set.

Note: The status parameter must be a null character if called from the interrupt environment.

### **Execution Environment**

The **devswqry** kernel service can be called from either the process or interrupt environment.

### **Return Values**

Indicates a successful operation.

**EINVAL** Indicates that the major device number portion of the devno parameter exceeds the maximum permitted

number of device switch entries.

#### **Related Information**

The **devswadd** kernel service, **devswchg** kernel service, **devswdel** kernel service.

Kernel Extension and Device Driver Management Kernel Services.

## d\_free\_dmamem Kernel Service

## **Purpose**

Frees an area of memory.

## **Syntax**

```
int d_free_dmamem(d_handle_t device_handle, void * addr, size_t size)
```

## **Description**

Exported, documented kernel service supported on PCI-based systems only. The **d\_free\_dmamem** kernel service frees the area of memory pointed to by the *addr* parameter. This area of memory must be allocated with the **d\_alloc\_dmamem** kernel service using the same *device\_handle*, and the *addr* must be the address returned from the corresponding **d\_alloc\_dmamem** call. Also, the size must be the same size that was used on the corresponding **d\_alloc\_dmamem** call.

#### Notes:

- Any memory allocated in a prior d\_alloc\_dmamem call must be explicitly freed with a d free dmamem call.
- 2. This service can be called from the process environment only.

## **Parameters**

device\_handleIndicates the dma handle.size\_t sizeSpecifies size of area to free.void \* addrSpecifies address of area to free.

### **Return Values**

- 0 Indicates successful completion.
- -1 Indicates underlying free service (xmfree or rmalloc) failed.

### **Related Information**

The d\_alloc\_dmamem kernel service.

# disable\_lock Kernel Service

# **Purpose**

Raises the interrupt priority, and locks a simple lock if necessary.

# **Syntax**

```
#include <sys/lock_def.h>
int disable_lock ( int_pri, lock_addr)
int int_pri;
simple_lock_t lock_addr;
```

#### **Parameters**

int\_pri Specifies the interrupt priority to set.

## **Description**

The **disable lock** kernel service raises the interrupt priority, and locks a simple lock if necessary, in order to provide optimized thread-interrupt critical section protection for the system on which it is executing. On a multiprocessor system, calling the disable lock kernel service is equivalent to calling the i disable and simple\_lock kernel services. On a uniprocessor system, the call to the simple\_lock service is not necessary, and is omitted. However, you should still pass a valid lock address to the disable lock kernel service. Never pass a NULL lock address.

### **Execution Environment**

The disable\_lock kernel service can be called from either the process or interrupt environment.

### Return Values

The **disable\_lock** kernel service returns the previous interrupt priority.

### Related Information

The i\_disable kernel service, simple\_lock\_init kernel service, simple\_lock kernel service, unlock enable kernel service.

Understanding Locking, Locking Kernel Services, Understanding Interrupts, I/O Kernel Services, and Interrupt Environment. in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# disablement checking resume Kernel Service

## **Purpose**

Indicates the end of a disabled code path that was exempted from detection of excessive interrupt disablement.

# **Syntax**

#include <svs/intr.h>

void disablement\_checking\_resume(long prev\_state)

#### **Parameters**

prev\_state

Specifies the disablement detection state to be restored. This value is returned by the disablement\_checking\_suspend kernel service.

# **Description**

The disablement\_checking\_resume service restores the disablement detection state to the value passed as prev\_state. This service must be called after reenabling interrupts at the end of an INTMAX critical section, not within it. This is because, in the case of an INTMAX critical section, the tick counting will have been deferred by the total disablement until the moment of enablement.

This service must be used in conjunction with the disablement\_checking\_suspend kernel service, which temporarily stops disablement detection.

**Note:** Error checking, including that for excessive interrupt disablement, can be enabled or disabled by the **errctrl** command.

### **Execution Environment**

The **disablement\_checking\_resume** service can be called from either the process or the interrupt environments.

## **Related Information**

The "disablement\_checking\_suspend Kernel Service."

The errctrl command.

# disablement\_checking\_suspend Kernel Service

## **Purpose**

Indicates the start of a disabled code path that is exempt from detection of excessive interrupt disablement.

## **Syntax**

#include <sys/intr.h>

long disablement checking suspend(void)

## **Description**

A call to the **disablement\_checking\_suspend** service temporarily disables the detection of excessive disablement for the duration of a portion of a critical section. For base level code, insert this call at the beginning of the exempt critical section immediately after it disables, or as soon as possible within interrupt handling code.

This service must be used in conjunction with the **disablement\_checking\_resume** kernel service, which resumes the prior disablement checking state.

**Note:** Error checking, including that for excessive interrupt disablement, can be enabled or disabled by the **errctrl** command.

### **Execution Environment**

The **disablement\_checking\_suspend** service can be called from either the process or the interrupt environments. Interrupts should be at least partially disabled at the time of the call.

#### Return Values

The **disablement\_checking\_suspend** service returns the previous suspension state to the caller. This value must be passed later to the resume function, which restores that state. This enables nesting of exempt critical sections.

#### **Related Information**

The "disablement\_checking\_resume Kernel Service" on page 80.

The errctrl command.

## d\_map\_attr Kernel Service

## **Purpose**

Changes the attributes associated with a DMA handle.

## **Syntax**

```
#include <sys/dma.h>
kerrno_t d_map_attr (handle, cmd, attr, attr size)
d handle t handle;
ulong cmd;
void * attr;
size t attr size;
```

## **Parameters**

handle Indicates the unique handle returned by the d\_map\_init\_ext kernel service.

Specifies one of the following flags: cmd

D\_ATTR\_SET\_MIN\_MAPMEM

Sets the minimum amount of I/O mappable memory. This is the logical memory change

and not the DMA bus memory change.

D\_ATTR\_SET\_DES\_MAPMEM

Sets the desired amount of I/O mappable memory. This is the logical memory change and

not the DMA bus memory change.

attr You must set this parameter to the value of size64\_t \*. This parameter sets the minimum or the

desired amount of I/O mappable memory depending on the specified value of the cmd parameter.

You must set this parameter to the value of sizeof(size64 t). This parameter sets the minimum or attr size

the desired amount of I/O mappable memory depending on the specified value of the cmd

parameter.

# **Description**

The d\_map\_attr kernel service can change certain attributes of the d\_handle\_t structure in case the needs of a device driver change during runtime. For example, if a device driver needs more DMA space at runtime, it can call the d map attr kernel service to request an increase in the map space. The d map attr kernel service is not an exported kernel service, but a bus specific utility routine determined by the d map init ext kernel service and provided to the caller through the d handle structure.

### **Execution Environment**

The d map attr kernel service can be called from the process environment at INTBASE. Serialization with other DMA services like the **d\_map\_page** service and the **d\_unmap\_page** service is the caller's responsibility.

#### **Return Values**

DMA\_SUCC Indicates a successful completion.

EINVAL D MAP ATTR Indicates that the specified cmd parameter is not valid.

ENOMEM\_D\_MAP\_ATTR Indicates that it is unable to change the minimum or desired I/O mappable memory.

### **Related Information**

The d map init ext kernel service.

# d\_map\_clear Kernel Service

## **Purpose**

Deallocates resources previously allocated on a d\_map\_init call.

## **Syntax**

```
#include <sys/dma.h>
void d_map_clear (*handle)
struct d_handle *handle
```

#### **Parameters**

handle Indicates the unique handle returned by the d\_map\_init kernel service.

## **Description**

The **d\_map\_clear** kernel service is a bus-specific utility routine determined by the **d\_map\_init** service that deallocates resources previously allocated on a **d\_map\_init** call. This includes freeing the **d\_handle** structure that was allocated by **d\_map\_init**.

Note: You can use the **D\_MAP\_CLEAR** macro provided in the /usr/include/sys/dma.h file to code calls to the **d\_map\_clear** kernel service.

### **Related Information**

The d\_map\_init kernel service.

# d\_map\_disable Kernel Service

# **Purpose**

Disables DMA for the specified handle.

# **Syntax**

#include <sys/dma.h>
int d\_map\_disable(\*handle)
struct d\_handle \*handle;

#### **Parameters**

handle Indicates the unique handle returned by **d\_map\_init**.

# **Description**

The **d\_map\_disable** kernel service is a bus-specific utility routine determined by the **d\_map\_init** kernel service that disables DMA for the specified *handle* with respect to the platform.

**Note:** You can use the **D\_MAP\_DISABLE** macro provided in the **/usr/include/sys/dma.h** file to code calls to the **d\_map\_disable** kernel service.

### **Return Values**

**DMA\_SUCC** Indicates the DMA is successfully disabled.

**DMA\_FAIL** Indicates the DMA could not be explicitly disabled for this device or bus.

### **Related Information**

The d map init kernel service.

## d\_map\_enable Kernel Service

## **Purpose**

Enables DMA for the specified handle.

## **Syntax**

#include <sys/dma.h>
int d\_map\_enable(\*handle)
struct d\_handle \*handle;

### **Parameters**

handle Indicates the unique handle returned by d\_map\_init.

## **Description**

The **d\_map\_enable** kernel service is a bus-specific utility routine determined by the **d\_map\_init** kernel service that enables DMA for the specified *handle* with respect to the platform.

Note: You can use the **D\_MAP\_ENABLE** macro provided in the /usr/include/sys/dma.h file to code calls to the **d\_map\_enable** kernel service.

### **Return Values**

**DMA\_SUCC** Indicates the DMA is successfully enabled.

**DMA\_FAIL** Indicates the DMA could not be explicitly enabled for this device or bus.

#### **Related Information**

The d\_map\_init kernel service.

# d\_map\_init Kernel Service

# **Purpose**

Allocates and initializes resources for performing DMA with PCI and ISA devices.

# **Syntax**

```
#include <sys/dma.h>
```

```
struct d_handle* d_map_init (bid, flags, bus_flags, channel)
```

```
int bid;
int flags;
int bus_flags;
uint channel;
```

#### **Parameters**

bid Specifies the bus identifier.flags Describes the mapping.bus\_flags Specifies the target bus flags.

channel Indicates the channel assignment specific to the bus.

## **Description**

The **d\_map\_init** kernel service allocates and initializes resources needed for managing DMA operations and returns a unique *handle* to be used on subsequent DMA service calls. The *handle* is a pointer to a **d\_handle** structure allocated by **d\_map\_init** from the pinned heap for the device. The device driver uses the function addresses provided in the *handle* for accessing the DMA services specific to its host bus. The **d\_map\_init** service returns a **DMA\_FAIL** error when resources are unavailable or cannot be allocated.

The *channel* parameter is the assigned channel number for the device, if any. Some devices and or buses might not have the concept of *channels*. For example, an ISA device driver would pass in its assigned DMA channel in the *channel* parameter.

**Note:** The possible flag values for the *flags* parameter can be found in **/usr/include/sys/dma.h**. These flags can be logically ORed together to reflect the desired characteristics.

### **Execution Environment**

The d\_map\_init kernel service should only be called from the process environment.

#### Return Values

**DMA\_FAIL** Indicates that the resources are unavailable. No registration was completed.

**struct d\_handle** \* Indicates successful completion.

#### Related Information

The d\_map\_clear kernel service, d\_map\_page kernel service, d\_unmap\_page kernel service, d\_map\_list kernel service, d\_unmap\_list kernel service, d\_map\_slave kernel service, d\_map\_disable kernel service, d\_map\_enable kernel service.

# d\_map\_init\_ext Kernel Service

# **Purpose**

Allocates and initializes resources for performing DMA with PCI and VDEVICE devices.

# **Syntax**

```
#include <sys/types.h>
#include <sys/dma.h>
#include <sys/kerrno.h>
kerrno_t d_map_init_ext (dma_input, info_size, handle_ptr)
d_info_t * dma_input;
size_t info_size;
d_handle_t * handle_ptr;
```

### **Parameters**

dma\_input Contains information like the bus identifier, flags, and so on. info\_size Specifies the size of the *dma\_input* parameter in bytes. handle\_ptr Contains the DMA handle returned upon success.

## **Description**

The d\_map\_init\_ext kernel service is very similar to the d\_map\_init kernel service. Unlike the d map init kernel service, the input argument list of the d map init ext kernel service is not limited and can be extended without breaking binary compatibility. Also, the d map init ext kernel service returns a **kerrno** t type return code which contains more RAS information rather than just the **DMA FAIL** value.

The caller of the d map init ext kernel service initializes the d info t structure and passes it into the d map init ext kernel service by reference. The size of the d info t type must match the info size parameter. This allows future expansion of the d info t type safely. If there is a size mismatch, the d map init ext kernel service fails. The d map init ext kernel service also creates a new private pool of I/O memory entitlement that can be used for DMA. The private pool is created by carving out a chunk of total I/O memory entitlement for the AIX® partition. Thus, in order to create a d handle t type successfully, there must be sufficient DMA PCI space and I/O memory entitlement.

The following structure is defined in the sys/dma.h file:

```
#define DMA MAX MAPPER NAME
                                32
typedef struct d info
     uint64 t
                 di_bid;
     uint64 t
                 di_flags;
                 di bus flags;
     uint64 t
                 di channel;
     uint64 t
     uint64 t
                 di min mapmem;
     uint64 t
                 di des mapmem:
     uint64 t
                 di max mapmem;
                  di_mapper_name[DMA_MAX_MAPPER NAME];
      char
} d info t;
```

Note: The first four fields of the d\_info\_t type match the four arguments of the d\_map\_init kernel service. Therefore, all flags and bus flags on the d map init kernel service are honored by the d\_map\_init\_ext kernel service except the DMA\_MAXMIN\_\* flags. The DMA\_MAXMIN\_\* flags are replaced with the di min mapmem, di des mapmem, and di max mapmem fields. They not only specify the required amount of DMA space, but also the necessary I/O memory entitlement for the device.

The di min mapmem parameter is the minimum amount of memory that the driver must be able to map for DMA in order to ensure the forward progress. The d\_map\_init\_ext kernel service fails if the minimum I/O memory entitlement requirement cannot be satisfied.

The di des mapmem parameter is the required amount of memory that the driver wants to be able to I/O map in order to have good throughput. In most cases, this is a value that a driver specifies through the DMA MAXMIN\_\* flag.

The di\_max\_mapmem parameter is the maximum amount of memory that the driver can ever map for DMA. This is the amount of DMA space that the d map init ext kernel service can allocate.

Note: While the I/O memory entitlement for a d handle t type can be changed at runtime through the **d map attr** kernel service, the DMA space cannot be changed dynamically.

The <u>di\_mapper\_name</u> parameter contains the name of the device instance using the DMA resources (for example, ent0, scsi1, and so on).

### **Execution Environment**

The d\_map\_init\_ext kernel service can be called from the process environment only.

### **Return Values**

0	Indicates a successful completion.
struct d_handle *	Indicates a successful completion.
ENOMEM_D_MAP_INIT_EXT_1	Indicates that the memory allocation failed. An AIX® error is logged.
ENOMEM_D_MAP_INIT_EXT_2	Cannot reserve I/O memory entitlement with the least amount specified by the <i>di_min_mapmem</i> parameter. An AIX® error is logged.
ENOMEM_D_MAP_INIT_EXT_3	Cannot allocate enough DMA space. An AIX® error is logged.
EINVAL_D_MAP_INIT_EXT_1	Indicates that some input argument is not valid. An AIX® error is logged in some cases.
EINVAL_D_MAP_INIT_EXT_2	Indicates that the combination of input arguments and system configuration is not valid. No AIX® error is logged.
EINVAL_D_MAP_INIT_EXT_3	Indicates that the RAS initialization failed. No AIX® error is logged.

### **Related Information**

The d\_map\_clear kernel service, d\_map\_page kernel service, d\_unmap\_page kernel service, d\_map\_list kernel service, d\_unmap\_list kernel service, d\_map\_slave kernel service, d\_unmap\_slave kernel service, d\_map\_disable kernel service, d\_map\_enable kernel service.

## d\_map\_list Kernel Service

## **Purpose**

Performs platform-specific DMA mapping for a list of virtual addresses.

# **Syntax**

```
#include <sys/dma.h>
int d_map_list (*handle, flags, minxfer, *virt_list, *bus_list)
struct d_handle *handle;
int flags;
int minxfer;
struct dio *virt_list;
struct dio *bus_list;
```

Note: The following is the interface definition for d\_map\_list when the DMA\_ADDRESS\_64 and DMA\_ENABLE 64 flags are set on the d map init call.

```
int d_map_list (*handle, flags, minxfer, *virt_list, *bus_list)
struct d_handle *handle;
int flags;
int minxfer;
struct dio_64 *virt_list;
struct dio_64 *bus list;
```

#### **Parameters**

handle Indicates the unique handle returned by the **d\_map\_init** kernel service.

flags Specifies one of the following flags:

DMA\_READ

Transfers from a device to memory.

**BUS DMA** 

Transfers from one device to another device.

DMA\_BYPASS

Do not check page access.

**DMA STMAP** 

Indicates a short-term mapping.

minxfer Specifies the minimum transfer size for the device. Specifies a list of virtual buffer addresses and lengths. virt\_list

Specifies a list of bus addresses and lengths. bus list

## **Description**

The d map list kernel service is a bus-specific utility routine determined by the d map init kernel service that accepts a list of virtual addresses and sizes and provides the resulting list of bus addresses. This service fills out the corresponding bus address list for use by the device in performing the DMA transfer. This service allows for scatter/gather capability of a device and also allows the device to combine multiple requests that are contiguous with respect to the device. The lists are passed via the dio structure. If the d\_map\_list service is unable to complete the mapping due to exhausting the capacity of the provided dio structure, the DMA DIOFULL error is returned. If the d map list service is unable to complete the mapping due to exhausting resources required for the mapping, the DMA\_NORES error is returned. In both of these cases, the bytes\_done field of the dio virtual list is set to the number of bytes successfully mapped. This byte count is a multiple of the minxfer size for the device as provided on the call to **d\_map\_list**. The *resid\_iov* field is set to the index of the remaining *d\_iovec* fields in the list. Unless the **DMA BYPASS** flag is set, this service verifies access permissions to each page. If an access violation is encountered on a page with the list, the DMA\_NOACC error is returned, and the bytes\_done field is set to the number of bytes preceding the faulting *iovec*. If the mapping is for short term (that is, it is unmapped as soon as the I/O is complete), you must set the DMA\_STMAP flag.

### Note:

- 1. When the **DMA NOACC** return value is received, no mapping is done, and the bus list is undefined. In this case, the *resid\_iov* field is set to the index of the *d\_iovec* that encountered the access violation.
- 2. You can use the **D MAP LIST** macro provided in the /usr/include/sys/dma.h file to code calls to the d map list kernel service.

#### **Return Values**

**DMA NORES** Indicates that resources were exhausted during mapping.

Note: d map list possible partial transfer was mapped. Device driver may continue with partial transfer and submit the remainer on a subsequent d\_map\_list call, or call d\_unmap\_list to undo the partial mapping. If a partial transfer is issued, then the driver must call **d unmap list** when the I/O is complete.

DMA DIOFULL Indicates that the target bus list is full. **Note: d\_map\_list** possible partial transfer was mapped. Device driver may continue with partial transfer and submit the remainder on a subsequent **d\_map\_list** call, or call **d\_unmap\_list** to undo the partial mapping. If a partial transfer is issued, then the driver must call **d\_unmap\_list** when the I/O is complete.

**DMA\_NOACC** Indicates no access permission to a page in the list.

.

**Note: d\_map\_list** no mapping was performed. No need for the device driver to call **d\_unmap\_list**, but the driver must fail the faulting I/O request, and resubmit any remainder in a subsequent **d\_map\_list** call.

**DMA\_SUCC** Indicates that the entire transfer successfully mapped.

**Note:** d\_map\_list successful mapping was performed. Device driver must call d\_unmap\_list when the I/O is complete. In the case of a long-term mapping, the driver must call d\_unmap\_list when the long-term mapping is no longer needed.

#### **Related Information**

The **d\_map\_init** kernel service, **d\_map\_init\_ext** kernel service.

## d\_map\_page Kernel Service

## **Purpose**

Performs platform-specific DMA mapping for a single page.

# **Syntax**

```
#include <sys/dma.h>
#include <sys/xmem.h>

int d_map_page(*handle, flags, baddr, *busaddr, *xmp)
struct d_handle *handle;
int flags;
caddr_t baddr;
uint *busaddr;
struct xmem *xmp;
```

Note: The following is the interface definition for d\_map\_page when the DMA\_ADDRESS\_64 and DMA\_ENABLE\_64 flags are set on the d\_map\_init call.

```
int d_map_page(*handle, flags, baddr, *busaddr, *xmp)
struct d_handle *handle;
int flags;
unsigned long long baddr;
unsigned long long *busaddr;
struct xmem *xmp;
```

#### **Parameters**

handle Indicates the unique handle returned by the **d\_map\_init** kernel service.

flags Specifies one of the following flags:

DMA\_READ

Transfers from a device to memory.

**BUS DMA** 

Transfers from one device to another device.

DMA\_BYPASS

Do not check page access.

**DMA STMAP** 

Indicates a short-term mapping.

baddr Specifies the buffer address. busaddr Points to the busaddr field.

Cross-memory descriptor for the buffer. xmp

## **Description**

The d map page kernel service is a bus-specific utility routine determined by the d map init or d map init ext kernel service that performs platform specific mapping of a single 4KB or less transfer for DMA master devices. The d map page kernel service is a fast-path version of the d map list service. The entire transfer amount must fit within a single page in order to use this service. This service accepts a virtual address and completes the appropriate bus address for the device to use in the DMA transfer. Unless the **DMA BYPASS** flag is set, this service also verifies access permissions to the page. If the mapping is for short term (that is, it is unmapped as soon as the I/O is complete), you must set the DMA\_STMAP flag.

If the buffer is a global kernel space buffer, the cross-memory descriptor can be set to point to the exported **GLOBAL** cross-memory descriptor, *xmem\_global*.

If the transfer is unable to be mapped due to resource restrictions, the **d\_map\_page** service returns DMA\_NORES. If the transfer is unable to be mapped due to page access violations, this service returns DMA\_NOACC.

Note: You can use the D\_MAP\_PAGE macro provided in the /usr/include/sys/dma.h file to code calls to the d map page kernel service.

### **Return Values**

DMA\_NORES Indicates that resources are unavailable.

Note: d\_map\_page no mapping is done, device driver must wait until resources are freed and attempt the **d\_map\_page** call again.

DMA NOACC Indicates no access permission to the page.

Note: d map page no mapping is done, device driver must fail the corresponding I/O request.

**DMA SUCC** Indicates that the busaddr parameter contains the bus address to use for the device transfer.

Note: d\_map\_page successful mapping was done, device driver must call d\_unmap\_page when I/O is complete, or when device driver is finished with the mapped area in the case of a long-term mapping.

### **Related Information**

The **d\_alloc\_dmamem** kernel service, **d\_map\_init** kernel service, **d\_map\_list** kernel service, **d\_map\_init\_ext** kernel service.

# d\_map\_slave Kernel Service

# **Purpose**

Accepts a list of virtual addresses and sizes and sets up the slave DMA controller.

# **Syntax**

```
#include <sys/dma.h>
int d_map_slave (*handle, flags, minxfer, *vlist, chan_flag)
struct d_handle *handle;
int flags;
int minxfer;
struct dio *vlist;
uint chan flag;
```

#### **Parameters**

handle Indicates the unique handle returned by the **d\_map\_init** kernel service.

flags Specifies one of the following flags:

DMA\_READ

Transfers from a device to memory.

**BUS DMA** 

Transfers from one device to another device.

**DMA BYPASS** 

Do not check page access.

minxfer Specifies the minimum transfer size for the device.

Vlist Specifies a list of buffer addresses and lengths.

chan\_flag Specifies the device and bus specific flags for the transfer.

# **Description**

The **d\_map\_slave** kernel service accepts a list of virtual buffer addresses and sizes and sets up the slave DMA controller for the requested DMA transfer. This includes setting up the system address generation hardware for a specific slave channel to indicate the specified data buffers, and enabling the specific hardware channel. The **d\_map\_slave** kernel service is not an exported kernel service, but a bus-specific utility routine determined by the **d\_map\_init** kernel service and provided to the caller through the **d\_handle** structure.

This service allows for scatter/gather capability of the slave DMA controller and also allows the device driver to coalesce multiple requests that are contiguous with respect to the device. The list is passed with the **dio** structure. If the **d\_map\_slave** kernel service is unable to complete the mapping due to resource, an error, **DMA\_NORES** is returned, and the **bytes\_done** field of the **dio** list is set to the number of bytes that were successfully mapped. This byte count is guaranteed to be a multiple of the *minxfer* parameter size of the device as provided to **d\_map\_slave**. Also, the *resid\_iov* field is set to the index of the remaining *d\_iovec* that could not be mapped. Unless the **DMA\_BYPASS** flag is set, this service will verify access permissions to each page. If an access violation is encountered on a page within the list, an error, **DMA\_NOACC** is returned and no mapping is done. The *bytes\_done* field of the virtual list is set to the number of bytes preceding the faulting *iovec*. Also in this case, the *resid\_iov* field is set to the index of the *d\_iovec* entry that encountered the access violation.

The virtual addresses provided in the *vlist* parameter can be within multiple address spaces, distinguished by the cross-memory structure pointed to for each element of the dio list. Each cross-memory pointer can point to the same cross-memory descriptor for multiple buffers in the same address space, and for global space buffers, the pointers can be set to the address of the exported GLOBAL cross-memory descriptor, xmem\_global.

The *minxfer* parameter specifies the absolute minimum data transfer supported by the device (the device blocking factor). If the device supports a minimum transfer of 512 bytes (floppy and disks, for example), the minxfer parameter would be set to 512. This allows the underlying services to map partial transfers to a correct multiple of the device block size.

#### Note:

- 1. The d map slave kernel service does not support more than one outstanding DMA transfer per channel. Attempts to do multiple slave mappings on a single channel will corrupt the previous mappings.
- 2. You can use the D MAP SLAVE macro provided in the /usr/include/sys/dma.h file to code calls to the d map clear kernel service.
- 3. The possible flag values for the chan flag parameter can be found in /usr/include/sys/dma.h. These flags can be logically ORed together to reflect the desired characteristics of the device and channel.
- 4. If the CH AUTOINIT flag is used then the transfer described by the vlist pointer is limited to a single buffer address with a length no greater than 4K bytes.

#### **Return Values**

DMA\_NORES Indicates that resources were exhausted during the mapping.

DMA\_NOACC Indicates no access permission to a page in the list.

DMA BAD MODE Indicates that the mode specified by the *chan\_flag* parameter is not supported.

#### **Related Information**

The d\_map\_init kernel service.

# dmp\_add Kernel Service

# **Purpose**

Specifies data to be included in a system dump by adding an entry to the master dump table. Callers should use the "dmp\_ctl Kernel Service" on page 96. This service is provided for compatibility purposes.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/dump.h>
int dmp add
( cdt func)
struct cdt * ( (*cdt func) ( ));
```

# **Description**

Kernel extensions use the dmp add service to register data areas to be included in a system dump. The dmp\_add service adds an entry to the master dump table. A master dump table entry is a pointer to a

function provided by the kernel extension that will be called by the kernel dump routine when a system dump occurs. The function must return a pointer to a component dump table structure.

When a dump occurs, the kernel dump routine calls the function specified by the cdt\_func parameter twice. On the first call, an argument of 1 indicates that the kernel dump routine is starting to dump the data specified by the component dump table. On the second call, an argument of 2 indicates that the kernel dump routine has finished dumping the data specified by the component dump table. Kernel extensions should allocate and pin their component dump tables and call the dmp add service during initialization. The entries in the component dump table can be filled in later. The cdt\_func routine must not attempt to allocate memory when it is called.

**Note:** In AIX® Version 7.1, this function automatically serializes CDT functions with I/O during dump time. The need for this function is device specific. Only the developer of the device can determine if this routine needs to be used. It is only recommended for devices that can be on the dump I/O path. Serializing I/O during dump time might degrade dump performance. Devices that are not on the dump path must either use the dmp ctl routine or the RAS system dump interface.

### The Component Dump Table

The component dump table structure specifies memory areas to be included in the system dump. The structure type (struct cdt) is defined in the /usr/include/sys/dump.h file. A cdt structure consists of a fixed-length header (cdt\_head structure) and an array of one or more cdt\_entry structures. The cdt\_head structure contains a component name field, which should be filled in with the name of the kernel extension, and the length of the component dump table. Each cdt entry structure describes a contiguous data area, giving a pointer to the data area, its length, a segment register, and a name for the data area.

### **Use of the Formatting Routine**

Each kernel extension that includes data in the system dump can install a unique formatting routine in the /var/adm/ras/dmprtns directory. The name of the formatting routine must match the component name field of the corresponding component dump table.

The dump image file includes a copy of each component dump table used to dump memory. A sample dump formatter is shipped with bos.sysmgt.serv aid in the /usr/samples/dumpfmt directory.

### Organization of the Dump Image File

Memory dumped for each kernel extension is laid out as follows in the dump image file. The component dump table is followed by a bit map for the first data area, then the first data area itself, then a bit map for the next data area, the next data area itself, and so on.

The bit map for a given data area indicates which pages of the data area are actually present in the dump image and which are not. Pages that were not in memory when the dump occurred were not dumped. The least significant bit of the first byte of the bit map is set to 1 (one) if the first page is present. The next least significant bit indicates the presence or absence of the second page and so on.

A macro for determining the size of a bit map is provided in the /usr/include/sys/dump.h file.

#### **Parameters**

cdt\_func

Specifies a function that returns a pointer to a component dump table entry. The function and the component dump table entry both must reside in pinned global memory.

#### **Execution Environment**

The **dmp\_add** kernel service can be called from the process environment only.

### **Return Values**

0 Indicates a successful operation.

-1 Indicates that the function pointer to be added is already present in the master dump table.

### **Related Information**

"dmp del Kernel Service" on page 101, and "dmp ctl Kernel Service" on page 96.

The exec: execl, execle, execlp, execv, execve, execvp, or exect Subroutine in AIX® Version 7.1 Technical Reference: Base Operating System and Extensions, Volume 1.

RAS Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# dmp\_compspec and dmp\_compext Kernel Services

# **Purpose**

Specifies a component and callback parameters to be included in the dump.

# **Syntax**

```
#include <sys/livedump.h>
kerrno_t dmp_compspec (flags, comp, anchor, extid, p1, p2, ..., NULL)
long flags;
long comp;
void *anchor;
dmp_extid_t *extid;
char *p1;
char *p2;
. . .
kerrno t dmp compext (extid, p1, p2, ..., NULL)
dmp extid t extid;
char *p1;
char *p2;
. . .
```

#### **Parameters**

anchor comp extid

Points to the associated Idmp\_parms\_t data structure or to an Idmp\_prepare\_t data structure. Specifies the component, specified as indicated by the flags.

Points to an item of dmp extid t type, for the dmp compspec kernel service, where an identifier is returned, if you use the dmp\_compext kernel service to provide additional parameters for the component being dumped. This identifier might then be specified to add additional parameters to the component using the **dmp compext** kernel service. The *extid* parameter can be NULL.

flags

You can specify the following values:

#### DCF\_FAILING

Indicates that this is the failing component. You can only specify one failing component.

#### DCF FIRST

Indicates that this component is to be dumped first. Normally components are dumped in the order specified.

#### Note:

- The DCF\_FIRST value is only valid when the anchor refers to an Idmp\_parms\_t data item. It is not valid when the callback receives the RASCD\_LDMP\_PREPARE command.
- The last component specified to be dumped first is the one dumped first.

#### DCF LEVEL0 - DCF LEVEL9

Indicates the detail level, 0 through 9, to dump this component. If none of these flags are set, the component is dumped at its current level.

#### DCF MINIMAL

Indicates the DCF\_LEVEL1 level.

#### DCF\_NORMAL

Indicates the DCF\_LEVEL3 level.

#### DCF DETAIL

Indicates the DCF LEVEL7 level.

#### DCF\_LONG

Indicates that the parameters are two parameters of long type. Rather than passing in an unlimited number of strings, a component can be passed in two long data items, as in the case with pseudo-components.

One and only one of the following component specification flags must be given. They specify how the component is specified in the dc\_component field:

#### DCF BYPNAME

Indicates that the component is specified by path name.

#### DCF BYLNAME

Indicates that the component is specified by logical alias.

#### DCF BYTYPE

Indicates that the component is specified by type.

#### DCF\_BYCB

Indicates that the component is specified by ras\_block\_t.

Specifies the component's parameters, the last of which must be NULL. If keyword parameters are being specified, The parameters must be strings, and contain the keyword and its values. If multiple keyword and value pairs appear in a single parameter, they are separated with blanks. For example, the p1 parameter can be foo=1234, and the p2 parameter can be bar=5678,16. Also, the p1 parameter can be foo=1234 bar=5678.

If the **DCF\_LONG** flag is set, two parameters of long type are passed in. In this case, the *p1* and *p2* parameters contain the values of long type, and no more parameters can be specified.

# **Description**

p1, p2 ...

The **dmp\_compspec** and **dmp\_compext** kernel services provide components and their callback parameters for a dump. You can only use these kernel services in a live dump.

The **dmp\_compspec** kernel service is used before you start a live dump with the **livedump** kernel service. You can also use this kernel service when a component's callback wants to include another component in a live dump, that is, when the callback receives the **RASCD\_LDMP\_PREPARE** command.

Multiple components can be included in a live dump.

The dmp\_compext function is used to provide additional parameters for a component.

### **Return Values**

Indicates a successful completion. EINVAL\_RAS\_DMP\_COMPSPEC\_FLAGS Indicates that the flags specification is not valid. EINVAL\_RAS\_DMP\_COMPSPEC\_COMP Indicates that the component specification is not valid. EINVAL RAS DMP\_COMPSPEC\_NOTAWARE Indicates that the specified component must support live EINVAL RAS DMP COMPSPEC ANCHOR Indicates that the anchor specification is not valid. EFAULT\_RAS\_DMP\_COMPSPEC\_ANCHOR Indicates that the storage the anchor parameter refers to is EFAULT RAS DMP\_COMPSPEC\_EXTID Indicates that the storage the extid parameter refers to is not valid. EFAULT\_RAS\_DMP\_COMPSPEC\_PARMS Indicates that a parameter address is not valid. EINVAL\_RAS\_LDMP\_ESTIMATE Indicates that the anchor parameter indicates a dump size estimate request, but the dmp\_compspec call was not made from the process environment. EINVAL RAS DMP COMPSPEC NOADD Indicates that components cannot be added to this dump, that is, the dump type flags, ldpr\_flags, have the LDT\_NOADD bit EINVAL RAS DMP COMPSPEC FAILING Indicates that the failing component has already been specified. ENOMEM\_RAS\_DMP\_COMPSPEC Indicates that no storage is available. EINVAL\_RAS\_DMP\_COMPEXT\_EXTID Indicates that the extid parameter does not refer to a valid component. EFAULT\_RAS\_DMP\_COMPEXT\_EXTID Indicates that the storage the extid parameter refers to is not valid. EFAULT\_RAS\_DMP\_COMPEXT\_PARMS Indicates that the storage a parameter refers to is not valid.

**EBUSY RAS DMP COMPEXT** Indicates that the specification of this component is complete. and no more parameters can be added. This happens if the component the *extid* parameter referred to has already completed its RASCD\_LDMP\_PREPARE processing.

**ENOMEM RAS DMP COMPEXT** Indicates that no storage is available.

### **Related Information**

The livedump kernel service, Idmp\_setupparms kernel service, and ras\_ret\_query\_parms kernel service.

# dmp\_ctl Kernel Service

# **Purpose**

Adds and removes entries to the master dump table.

# **Syntax**

```
#include <sys/types.h>
     #include <errno.h>
     #include <sys/dump.h>
     int dmp ctl(op, parmp)
     int op;
     struct dmpctl data *parmp;
```

# **Description**

The dmp ctl kernel service is used to manage dump routines. It replaces the dmp\_add and dmp\_del kernel services which are still supported for compatibility reasons. The major differences between routines added with the dmp\_add() command and those added with the dmp\_ctl() command are:

- The routines are invoked differently from routines added with the dmp\_add kernel service. Routines added using the dmp\_ctl kernel service return a void pointer, to a dump table or to a dump size estimate.
- · Routines added with the dmp\_ctl kernel service are expected to ignore functions they don't support. For example, they should not trap if they receive an unrecognized request. This allows future functionality to be added without all users needing to change.

The dmp\_ctl kernel service is used to request that an amount of memory be set aside in a global buffer. This will then be used by the routine to store data not resident in memory. An example of such data is dump data provided by an adapter. Without a global buffer, the data would need to be placed into a pinned buffer allocated at configuration time. Each component would need to allocate its own pinned buffer.

The system dump facility maintains a global buffer for such data. This buffer is allocated when it is first requested, with the requested size. Another dump routine requesting more data causes the buffer to be reallocated with the larger size. Since this buffer must be maintained in pinned storage for the life of the system, only ask for as much memory as is required. Asking for an excessive amount of storage will compromise system performance by reserving too much pinned storage.

Any dump routine using the global buffer is called whenever dump data is required. Routines are only called once to provide such data. Their dump table addresses are saved and used if the dump is restarted.

**Note:** The **dmp ctl** kernel service can also be used by a dump routine to report a routine failure. This may be necessary if the routine detects that it can't dump what needs to be dumped for some reason such as corruption of a data structure.

Note: Beginning with AIX® 6.1 with the 6100-02 Technology Level, the dmp\_ctl kernel service supports that DMPFUNC SERIALIO operation flag.

#### **Dump Tables**

A dump routine returns a component dump table that begins with DMP MAGIC, which is the magic number for the 32- or 64-bit dump table. If the unlimited sized dump table is used, the magic number is DMP\_MAGIC\_U and the cdt\_u structure is used. If this is the case, the dump routine is called repeatedly until it returns a null cdt u pointer. The purpose of the unlimited size dump table is to provide a way to dump an unknown number of data areas without having to preallocate the largest possible array of cdt entry elements as is required for the classic dump table. The definitions for dump tables are in the sys/dump.h include file.

### **Parameters**

dmp ctl operations and the dmpctl data structure are defined in the dump.h text file.

op Specifies the operation to perform.
--

```
parmp
           Points to a dmpctl_data structure containing values for the specified operation. The dmpctl_data
           structure is defined in the /usr/include/sys/dump.h file as follows:
           /* Dump Routine failures data. */
           struct rtnf {
                  int rv;
                                            /* error code. */
                  ulong vaddr;
                                           /* address. */
                  vmhandle t handle;
                                            /* handle */
           };
                         void *((*__CDTFUNCENH)(int op, void *buf));
           typedef
           struct dmpctl data {
                  int dmpc magic;
                                             /* magic number
                                            /* dump
                                                                        flags. */
                  int dmpc_flags;
                                                          routine
                  CDTFUNCENH dmpc func;
                  union {
                         u longlong t bsize; /* Global buffer size requested. */
                         struct __rtnf rtnf;
                  } dmpc_u;
           };
           #define
                         DMPC MAGIC1 0xdcdcdc01
           #define
                         DMPC MAGIC DMPC MAGIC1
           #define
                         dmpc bsize dmpc u.bsize
           #define dmpcf_rv dmpc_u.rtnf.rv
           #define dmpcf_vaddr dmpc_u.rtnf.vaddr
           #define dmpcf_handle dmpc_u.rtnf.handle
```

The supported operations and their associated data are:

DMPCTL_ADD	Adds the specified dump routine to the master dump table. This requires a pointer to the function and function type flags. Supported type flags are:
	DMPFUNC_CALL_ON_RESTART  Calls this function again if the dump is restarted. A dump function is only called once to provide dump data. If the function must be called and the dump is restarted on the secondary dump device, then this flag must be set. The DMPFUNC_CALL_ON_RESTART flag must be set if this function uses the global dump buffer. It also must be set if the function uses an unlimited size dump table, a table with DMP_MAGIC_U as the magic number.
	DMPFUNC_GLOBAL_BUFFER  This function uses the global dump buffer. The size is specified using the dmpc_bsize field.
	DMPFUNC_SERIALIO  Enables serialized I/O during dump time. The need for this flag is device specific. Only the developer of the device can determine if this flag needs to be set. It is only recommended for devices that can be on the dump I/O path. Serializing I/O during dump time can degrade dump performance. The default, without this flag, is to allow I/O to occur in parallel with CDT function calls.
DMPCTL_DEL	Deletes the specified dump function from the master dump table.
DMPCTL_RTNFAILURE	Reports an inability to dump required data. The routine must set the dmpc_func, dmpcf_rV, dmpcf_vaddr, and dmpcf_handle fields.

Dump function invocation parameters:

operation code	Specifies the operation the routine is to perform. Operation codes are:
	DMPRTN_START The dump is starting for this dump table. Provide data.
	DMPRTN_DONE  The dump is finished. This call is provided so that a dump routine can do any cleanup required after a dump. This is specific to a device for which information was gathered. It does not free memory, since such memory must be allocated before the dump is taken.
	DMPRTN_AGAIN  Provide more data for this unlimited dump table. The routine must have first passed back a dump table beginning with DMP_MAGIC_U. When finished, the function must return a NULL.
	DMPRTN_ESTIMATE  Provide a size estimate. The function must return a pointer to an item of type dmp_sizeest_t. See the examples later in this article.
buffer pointer	This is a pointer to the global buffer, or NULL if no global buffer space was requested.

# **Return Values**

0	Returned if successful.
EINVAL	Returned if one or more parameter values are invalid.
ENOMEM	Returned if the global buffer request can't be satisfied.
EEXIST	Returned if the dump function has already been added.

# **Examples**

1. To add a dump routine (dmprtn) that can be called once to provide data, type:

```
void *dmprtn(int op, void *buf);
          struct cdt cdt;
          dmp_sizeest_t estimate;
          config()
                  struct dmpctl_data parm;
                  parm.dmpc_magic = DMPC_MAGIC1;
                  parm.dmpc_func = dmprtn;
                 parm.dmpc_flags = 0;
                  ret = dmp ctl(DMPCTL ADD, &parm);
          }
          * Dump routine.
          * input:
             op - dump routine operation.
             buf - NULL since no global buffer is used.
          * returns:
              A pointer to the component dump table.
          */
          void *
          dmprtn(int op, void *buf)
```

```
void *ret;
                       switch(op) {
                       case DMPRTN_START: /* Provide dump data. */
                               ret = (void *)&cdt;
                               break;
                       case DMPRTN ESTIMATE:
                               ret = (void *)&estimate;
                               break;
                       default:
                                       break;
                       return(ret);
2. To add a dump routine (dmprtn) that requests 16 kb of global buffer space, type:
              #define BSIZ 16*1024
              dmp_sizeest_t estimate;
              config()
              {
                       parm.dmpc_magic = DMPC_MAGIC1;
                      parm.dmpc_func = dmprtn;
parm.dmpc_flags = DMPFUNC_CALL_ON_RESTART|DMPC_GLOBAL_BUFFER;
                       parm.dmpc bsize = BSIZ;
                       ret = dmp_ctl(DMPCTL_ADD, &parm);
              }
              /*
               * Dump routine.
               * input:
                   op - dump routine operation.
                  buf - points to the global buffer.
                   Return a pointer to the dump table or to the estimate.
               */
              void *
              dmprtn(int op, void *buf)
                       void *ret;
                       switch(op) {
                       case DMPRTN_START: /* Provide dump data. */
                               (Put data in buffer at buf.)
                               ret = (void *)&cdt;
                               break;
                       case DMPRTN ESTIMATE:
                               ret = (void *)&estimate;
                               break;
                      default:
                                       break;
```

return(ret);

### **Related Information**

The Dump Special File in AIX Version 7.1 Files Reference.

RAS Kernel Services and System Dump Facility in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# dmp\_del Kernel Service

# **Purpose**

Deletes an entry from the master dump table. Callers should use the "dmp ctl Kernel Service" on page 96. This service is provided for compatibility purposes.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/dump.h>
dmp_del ( cdt_func_ptr)
struct cdt * ( (*cdt func ptr) ( ));
```

# **Description**

Kernel extensions use the **dmp del** kernel service to unregister data areas previously registered for inclusion in a system dump. A kernel extension that uses the "dmp\_add Kernel Service" on page 92 to register such a data area can use the dmp del service to remove this entry from the master dump table.

#### **Parameters**

cdt\_func\_ptr

Specifies a function that returns a pointer to a component dump table. The function and the component dump table must both reside in pinned global memory.

#### **Execution Environment**

The **dmp del** kernel service can be called from the process environment only.

#### **Return Values**

- Indicates a successful operation.
- -1 Indicates that the function pointer to be deleted is not in the master dump table.

#### **Related Information**

long unused;

kerrno_t dmp_ct (flags, anchor, name, rasb, sz)
long flags;
void *anchor;
char *name;
ras_block_t rasb;
size t sz;
```

#### **Parameters**

anchor Points to the associated <code>Idmp\_parms\_t</code> data structure or to an <code>Idmp\_prepare\_t</code> data structure.

flags The flags parameter can be one or more of the following values:

**DCF FIRST** 

Specifies that this component is to be dumped first. Normally components are dumped in the order specified.

Note: The last component specified to be dumped first is the one dumped first.

DCF LEVEL0 - DCF LEVEL9

Dumps the component at the specified detail level, 0 through 9. If none of these flags are

set, the component is dumped at CD\_LVL\_NORMAL, detail level 3.

Specifies the name of the pseudo-component's dump table in the dump. The *name* parameter is only valid for the **dmp\_eaddr** kernel service. You must specify the *name* parameter to NULL for the **dmp\_context**, **dmp\_tid**, **dmp\_pid**, **dmp\_errbuf**, **dmp\_mtrc**, **dmp\_systrace**, and **dmp\_ct** kernel

services.

*unused* You must specify this parameter to NULL or 0. The remaining parameters are pseudo-component dependent:

dmp\_eaddr

name

addr Specifies the effective address of the memory to be dumped.

sz Specifies the length of the memory in bytes.

dmp\_context

ctx\_type Specifies the context to dump. It can be one of the following values:

DMP\_CTX\_CUR

To dump the current context.

**DMP CTX PREV** 

To dump the previous context.

DMP\_CTX\_SPEC

To dump the context specified by the *p2* parameter. The *p2* parameter must contain the address of the **ksmtsave** structure for the context.

DMP\_CTX\_RWA

To dump the context from the supplied recovery work area. The *p2* parameter must contain the address of the recovery work area, rwa.

DMP\_CTX\_BID or DMP\_CTX\_LCPUID

To dump the context for the processor specified by the p2 parameter. You can specify the processor either by the bind ID or by the logical ID.

DMP CTX TID

To dump the context of the thread specified by the *p2* parameter, which must contain the thread ID.

Specifies the address of the context, the logical processor ID, the bind ID, or the thread ID dependent on the value of the *ctx\_type* parameter.

dependent on the value of the

dmp\_tid

p2

tid Specifies the ID of the thread to dump.

dmp\_pid

pid Specifies the ID of the process to dump.

dmp\_errbuf

Specifies the kernel workload partition (WPAR) ID of the partition's error logging buffer to dump. erridx

The value of 0 stands for the global buffer.

dmp mtrc

Specifies the amount of common to dump. com\_sz Specifies the amount of rare data to dump. rare\_sz

dmp\_systrace

Specifies the amount of system trace data to dump. If the sz parameter is set to 0, all the buffered

trace data is dumped, up to the amount allowed by the detail level.

dmp\_ct

rasb Specifies the ras\_block\_t of the component whose component trace is to be dumped.

Specifies the amount of data to dump. If the sz parameter is set to 0, all the components' trace SZ

data is dumped, up to the limit for the detail level.

# **Description**

The **dmp eaddr** kernel service dumps memory by effective address.

The **dmp\_context** kernel service dumps the specified thread context.

The **dmp\_tid** kernel service dumps the kernel data for a thread.

The **dmp pid** kernel service dumps the kernel data for a process.

The **dmp errbuf** kernel service dumps the error logging buffer for the specified partition.

The dmp\_mtrc kernel service dumps entries from the lightweight memory trace buffers.

The **dmp systrace** dumps entries from the system trace buffers.

The **dmp** ct dumps component trace entries.

#### **Execution Environment**

EINVAL RAS DMP COMPSPEC NOADD

ENOMEM\_RAS\_DMP\_COMPSPEC

**EINVAL RAS DMP EADDR** 

EINVAL RAS DMP CONTEXT

The dmp\_eaddr, dmp\_context, dmp\_tid, dmp\_pid, dmp\_errbuf, dmp\_mtrc, dmp\_systrace, and **dmp** ct kernel services can be called from either the process or interrupt environment.

#### **Return Values**

Indicates a successful completion.

EINVAL\_DMP\_PSEUDO Indicates that the name parameter is not valid. EINVAL\_DMP\_CHECK\_ANCHOR Indicates that no anchor was specified, or the anchor parameter does not point to an area of Idmp\_parms\_t or

ldmp\_prepare\_t type.

EFAULT DMP\_CHECK\_ANCHOR Indicates that the storage specified by the anchor parameter

is not valid.

EINVAL\_RAS\_DMP\_COMPSPEC\_FLAGS Indicates that the flags specification is not valid. This error

also occurs if the DCF\_FIRST flag is specified when the

anchor is an Idmp\_prepare\_t data item.

Indicates that components cannot be added to this dump.

Indicates that the storage is not sufficient. Indicates that the flags parameter is not valid.

Indicates that the parameter of the dmp\_context kernel service is not valid. This is also returned if the p2 parameter is

not used, but is not NULL.

ENOENT\_RAS\_DMP\_CONTEXT\_CTX\_NOTFOUND

EFAULT\_RAS\_DMP\_CONTEXT

Indicates that the specified context was not found.

Indicates that the storage the specified context pointer points

to is not valid.

EINVAL\_RAS\_DMP\_TID Indicates that the parameter of the dmp\_tid kernel service is

not valid.

EINVAL RAS DMP PID Indicates that the parameter of the dmp\_pid kernel service is

not valid

EINVAL\_RAS\_DMP\_ERRBUF Indicates that the parameter of the dmp\_errbuf kernel service

is not valid.

ECHRNG RAS DMP ERRBUF Indicates that the erridx parameter is out of range.

EINVAL RAS DMP MTRC Indicates that the parameter of the dmp\_mtrc kernel service

is not valid.

ENOENT\_RAS\_DMP\_MTRC Indicates that the lightweight memory trace is not active. EINVAL\_RAS\_DMP\_SYSTRACE Indicates that the parameter of the dmp systrace kernel

service is not valid.

ENOENT\_RAS\_DMP\_SYSTRACE Indicates that the system trace is not active.

Indicates that the parameter of the dmp\_ct kernel service is EINVAL RAS DMP\_CT

ENOMEM RAS DMP\_CT Indicates that the storage is not sufficient.

EINVAL RAS DMP CT GETPATH Indicates that the specified component is not valid. EINVAL\_RAS\_DMP\_CT\_LOOKUP

Indicates that an error occurred while this component was

being validated.

**ENOTSUP RAS DMP CT** Indicates that the specified component does not have a

component trace.

#### **Related Information**

The **livedump** kernel service and **dmp kernext** kernel service.

# dmp\_kernext Kernel Service

# Purpose

Causes the specified kernel extension to be shipped with the live dump for symbol resolution.

# **Syntax**

#include <sys/dump.h>

kerrno t dmp kernext (anchor, ptr)void \*anchor; void \*ptr:

#### **Parameters**

anchor Points to either an <a href="mailto:ldmp\_prepare\_t">ldmp\_prepare\_t</a> structure.

Specifies an address within the kernel extension. If the value is 0, the dump includes information ptr

for all loaded kernel extensions.

# Description

The dmp kernext kernel service causes snap to package the specified kernel extension with the current live dump. This also includes loader information for the extension in the dump. You can specify the extension by setting the ptr parameter to a text or data address within the extension. The extension's file name is noted in the dump, and snap can be used to cause this file to be bundled with the snap data when the dump is collected for sending to IBM<sup>®</sup>.

### **Execution Environment**

The dmp\_kernext kernel service can be called from either the process or interrupt environment.

### **Return Values**

Indicates a successful completion.

EINVAL RAS DMP\_KERNEXT Indicates that the anchor parameter is not valid.

#### **Related Information**

The livedump kernel service.

The snap command in AIX Version 7.1 Commands Reference, Volume 5.

# d\_roundup Kernel Service

# **Purpose**

Rounds the value length up to a given number of cache lines.

# **Syntax**

int d roundup(length)

int length;

### **Parameter**

Specifies the size in bytes to be rounded. length

# **Description**

To maintain cache consistency, buffers must occupy entire cache lines. The **d\_roundup** service helps provide that function by rounding the value length up to a given number in integer form.

### **Execution Environment**

The **d** roundup service can be called from either the process or interrupt environment.

#### **Related Information**

The d\_align kernel service, d\_cflush kernel service.

Understanding Direct Memory Access (DMA) Transfers in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# d\_sync\_mem Kernel Service

# **Purpose**

Allows a device driver to indicate that previously mapped buffers may need to be refreshed.

# **Syntax**

int d\_sync\_mem(d\_handle\_t handle, dio\_t blist)

# **Description**

The **d sync mem** service allows a device driver to indicate that previously mapped buffers may need to be refreshed, either because a new DMA is about to start or a previous DMA has now completed. d\_sync\_mem is not an exported kernel service, but a bus-specific utility determined by d\_map\_init based on platform characteristics and provided to the caller through the d handle structure. d sync mem allows the driver to identify additional coherency points beyond those of the initial mapping (d\_map\_list) and termination of the mapping (d\_unmap\_list). Thus d\_sync\_mem provides a way to long-term map buffers and still handle potential data consistency problems.

The blist parameter is a pointer to the **dio** structure that describes the initial mapping, as returned by d map list. Note that for bounce buffering, the data direction is also implicitly defined by this initial mapping.

- If the map list call describes a transfer from system memory to a device, subsequent d sync mem calls using the corresponding blist will synchronize the memory view. This assumes that the original system memory pages contain the correct data.
- · If the map list call describes a transfer from a device to system memory, then subsequent d sync mem calls will synchronize the memory view. This assumes that the bounce pages the device directly accessed contained the correct data.

Note: You can use the D SYNC MEM macro provided in the /usr/include/sys/dma.h file to code calls to the d sync mem kernel service.

#### **Parameters**

d\_handle\_t Indicates the unique dma handle returned by d\_map\_init.

List of vectors returned by original d\_map\_list. dio\_t blist

#### **Return Values**

DMA\_SUCC Buffers described by the blist have been synchronized.

Buffers could not be synchronized. DMA FAIL

#### **Related Information**

### **DTOM Macro for mbuf Kernel Services**

# **Purpose**

Converts an address anywhere within an **mbuf** structure to the head of that **mbuf** structure.

# **Syntax**

#include <sys/mbuf.h>

**DTOM** ( bp);

#### **Parameter**

bp Points to an address within an mbuf structure.

# **Description**

The DTOM macro converts an address anywhere within an mbuf structure to the head of that mbuf structure. This macro is valid only for mbuf structures without an external buffer (that is, with the M\_EXT flag not set).

This macro can be viewed as the opposite of the MTOD macro, which converts the address of an mbuf structure into the address of the actual data contained in the buffer. However, the DTOM macro is more general than this view implies. That is, the input parameter can point to any address within the mbuf structure, not merely the address of the actual data.

# **Example**

The **DTOM** macro can be used as follows:

```
*bp;
char
struct mbuf
                    *m;
m = DTOM(bp);
```

### **Related Information**

The MTOD macro for mbuf Kernel Services.

I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# d unmap list Kernel Service

# **Purpose**

Deallocates resources previously allocated on a d map list call.

# **Syntax**

```
#include <sys/dma.h>
void d unmap list (*handle, *bus list)
struct d handle *handle
struct dio *bus list
```

Note: The following is the interface definition for d unmap list when the DMA ADDRESS 64 and DMA ENABLE 64 flags are set on the d map init call.

```
void d unmap list (*handle,
*bus l\bar{i}st)
struct d handle *handle;
struct dio 64 *bus list;
```

#### **Parameters**

handle Indicates the unique handle returned by the d map init kernel service.

bus\_list Specifies a list of bus addresses and lengths.

# **Description**

The d\_unmap\_list kernel service is a bus-specific utility routine determined by the d\_map\_init kernel service that deallocates resources previously allocated on a d map list call.

The **d unmap list** kernel service must be called after I/O completion involving the area mapped by the prior d\_map\_list call. Some device drivers might choose to leave pages mapped for a long-term mapping of certain memory buffers. In this case, the driver must call dunmap\_list when it no longer needs the long-term mapping.

Note: You can use the D\_UNMAP\_LIST macro provided in the /usr/include/sys/dma.h file to code calls to the d unmap list kernel service. If not, you must ensure that the d unmap list function pointer is non-NULL before attempting the call. Not all platforms require the unmapping service.

### **Related Information**

The **d\_map\_init** kernel service, **d\_map\_list** kernel service.

# d\_unmap\_slave Kernel Service

## **Purpose**

Deallocates resources previously allocated on a d\_map\_slave call.

# **Syntax**

#include <sys/dma.h> int d unmap slave (\*handle) struct d\_handle \*handle;

### **Parameters**

handle Indicates the unique handle returned by the **d\_map\_init** kernel service.

# **Description**

The d unmap slave kernel service deallocates resources previously allocated on a d map slave call, disables the physical DMA channel, and returns error and status information following the DMA transfer. The d unmap slave kernel service is not an exported kernel service, but a bus-specific utility routine that is determined by the **d** map init kernel service and provided to the caller through the **d** handle structure.

Note: You can use the D UNMAP SLAVE macro provided in the /usr/include/sys/dma.h file to code calls to the d unmap slave kernel service. If not, you must ensure that the d unmap slave function pointer is non-NULL before attempting to call. No all platforms require the unmapping service.

The device driver must call dunmap\_slave when the I/O is complete involving a prior mapping by the d map slave kernel service.

Note: The d\_unmap\_slave kernel should be paired with a previous d\_map\_slave call. Multiple outstanding slave DMA transfers are not supported. This kernel service assumes that there is no DMA in progress on the affected channel and deallocates the current channel mapping.

#### **Return Values**

DMA\_SUCC Indicates successful transfer. The DMA controller did not report any errors and that

the Terminal Count was reached.

DMA\_TC\_NOTREACHED Indicates a successful partial transfer. The DMA controller reported the Terminal

Count reached for the intended transfer as set up by the d\_map\_slave call. Block devices consider this an erro; however, for variable length devices this may not be

an error.

DMA\_FAIL Indicates that the transfer failed. The DMA controller reported an error. The device

driver assumes the transfer was unsuccessful.

### **Related Information**

The **d\_map\_init** kernel service.

# d\_unmap\_page Kernel Service

# **Purpose**

Deallocates resources previously allocated on a d\_unmap\_page call.

# **Syntax**

```
#include <sys/dma.h>
void d_unmap_page (*handle, *busaddr)
struct d handle *handle
uint *busaddr
```

Note: The following is the interface definition for d unmap page when the DMA ADDRESS 64 and DMA ENABLE 64 flags are set on the d map init call.

```
int d unmap page(*handle,
*busaddr)
struct d handle *handle;
unsigned long long *busaddr;
```

### **Parameters**

handle Indicates the unique handle returned by the **d\_map\_init** kernel service.

Points to the busaddr field. busaddr

# **Description**

The d unmap page kernel service is a bus-specific utility routine determined by the d map init kernel service that deallocates resources previously allocated on a d map page call for a DMA master device.

The d\_unmap\_page service must be called after I/O completion involving the area mapped by the prior d\_map\_page call. Some device drivers might choose to leave pages mapped for a long-term mapping of certain memory buffers. In this case, the driver must call d\_unmap\_page when it no longer needs the long-term mapping.

Note: You can use the D\_UNMAP\_PAGE macro provided in the /usr/include/sys/dma.h file to code calls to the **d\_unmap\_page** kernel service. If not, you must ensure that the **d\_unmap\_page** function pointer is non-NULL before attempting the call. Not all platforms require the unmapping service.

## **Related Information**

The d map init kernel service.

# dr\_reconfig System Call

# **Purpose**

Determines the nature of the DLPAR request.

# **Syntax**

```
#include <sys/dr.h>
int dr reconfig (flags, dr info)
int flags;
dr_info_t *dr_info;
```

# **Description**

The dr\_reconfig system call is used by DLPAR-aware applications to adjust their use of resources in relation to a DLPAR request. Applications are notified about the usage through the SIGRECONFIG signal, which is generated three times for each DLPAR event.

The first time is to check with the application whether the DLPAR event should be continued. Using the DR\_EVENT\_FAIL flag, an application can indicate that the operation should be aborted, if it is not DLPAR-safe and its operation is considered vital to the system.

The application is notified the second time before the resource is added or removed, and the third time afterwards. Applications must attempt to control their scheduling priority and policy to guarantee timely delivery of signals. The system does not guarantee that every signal that is sent is delivered before advancing to the next step in the algorithm.

The dr\_reconfig system call can also be used to notify applications about the changes to the workload partition that they are running. Applications are notified about changes to the CPU, memory capacity, and resources set.

The **dr reconfig** interface is signal-handler safe and can be used by multi-threaded programs.

The **dr** info structure is declared within the address space of the application. The kernel fills out data in this structure relative to the current DLPAR request. The user passes this structure identifying the current DLPAR request, as a parameter to the kernel when the DR RECONFIG DONE flag is used. The DR RECONFIG DONE flag is used by the application to notify the kernel that necessary action to adjust their use of resources has been taken in response to the SIGRECONFIG signal sent to them. It is expected that the signal handler associated with the SIGRECONFIG signal calls the interface with the DR QUERY flag to identify the phase of the DLPAR event, takes the appropriate action, and calls the interface with the DR RECONFIG DONE flag to indicate to the kernel that the signal has been handled. This type of acknowledgment to the kernel in each of the DLPAR phases enables a DLPAR event to perform efficiently.

With the addition of new fields to the **dr info** structure, DR-aware applications can support Micro-Partitioning<sup>™</sup>.

The bindproc, softpset, and hardpset bits are only set, if the request is to remove a cpu. If the bindproc is set, the process or one of its threads has a bindprocessor attachment, which must be resolved. If the softpset bit is set, the process has a Workload Manager (WLM) attachment, which can be changed by calling the appropriate WLM interface or by invoking the appropriate WLM command. If the hardpset bit is set, the appropriate **pset** API must be used.

**Note:** The bcpu and lcpu fields identify the cpu being removed and do not necessarily indicate that the process has a dependency that must be resolved. The bindproc, softpset, and hardpset bits are provided for that purpose.

The plock and pshm bits are only set, if the request is to remove memory and the process has plock memory or is attached to a pinned shared memory segment. If the plock bit is set, the process callsplock to unpin itself. If the pshm bit is set, the application has pinned shared memory segments, which may need to be detached. The memory remove request can succeed in any case, if there is enough pinnable memory in the system, so an action in this case is not necessarily required. The field sys pinnable frames provides this information, however, this value and other statistical values are just approximations. They reflect the state of the system at the time of the request. They are not updated during the request. The current size of physical memory can be determined by referencing the \_system\_configuration.physmem field.

To provide support for virtual real memory related DR operations, a new field, dr op, has been added to the **dr\_info** structure. The  $dr_{op}$  field provides information about the current DR operation. Additionally, all future DR operations use this field and the previously used resource bits will no longer be extended.

#### dr wlm info Structure

```
typedef struct dr wlm info {
  unsigned int cpu\_ad\overline{d}: 1; // cpu wlm resource add for the WPAR
  unsigned int cpu rem : 1; // cpu wlm resource remove for the WPAR

                                          current variable capacity weight
                                          if var_wgt bit is set.
   int
         delta_cap;
                         // delta capacity added/removed to
                                          current value depending on add/rem
                                          bit flag value above
                                       //
    dr wlm info t dr wlm;
                               // DR info for the WPAR
    ushort
             dr_op; // type of DR operation
   ushort
              dr pad;
                          // reserved pad field
                mem_capacity; // partition's entitled I/O memory or variable capacity.
   size64 t
    ssize64 t
               delta mem capacity; // amount of I/O being added/removed
    int reserved[2];
} dr info t;
```

### **Parameters**

flags

The following values are supported:

#### DR QUERY

Identifies the current DLPAR request and the actions that the application must take to comply with the current DLPAR request. This information is returned to the caller in the structure identified by the *dr\_info* parameter.

#### DR EVENT FAIL

Fail the current DLPAR event. Root authority is required.

#### DR RECONFIG DONE

This flag is used with the DR\_QUERY flag. The application notifies the kernel that the actions it took to comply with the current DLPAR request are now complete. The dr\_info structure identifying the DLPAR request that was returned is passed as an input parameter.

Contains the address of a dr\_info structure, which is declared with the address space of the application.

dr\_info

### **Return Values**

Upon success, the dr reconfig system call returns a zero. If unsuccessful, it returns negative one and sets the **errno** variable to the appropriate error value.

#### **Error Codes**

**EINVAL ENXIO EPERM EINPROGRESS**  Invalid flags.

No DLPAR event in progress.

Root authority required for DR\_EVENT\_FAIL.

Cancellation of DLPAR event may only occur in the check phase.

### **Related Information**

Making Programs DLPAR-Aware Using DLPAR APIs in AIX® Version 7.1 General Programming Concepts: Writing and Debugging Programs.

## e\_assert\_wait Kernel Service

# **Purpose**

Asserts that the calling kernel thread is going to sleep.

# **Syntax**

```
#include <sys/sleep.h>
void e_assert_wait ( event word, interruptible)
tid t *event word;
boolean_t interruptible;
```

#### **Parameters**

Specifies the shared event word. The kernel uses the event word parameter as the anchor event\_word

to the list of threads waiting on this shared event.

interruptible Specifies if the sleep is interruptible.

# **Description**

The e assert wait kernel service asserts that the calling kernel thread is about to be placed on the event list anchored by the event word parameter. The interruptible parameter indicates wether the sleep can be interrupted.

This kernel service gives the caller the opportunity to release multiple locks and sleep atomically without losing the event should it occur. This call is typically followed by a call to either the e\_clear\_wait or e block thread kernel service. If only a single lock needs to be released, then the e sleep thread kernel service should be used instead.

The e assert wait kernel service has no return values.

#### **Execution Environment**

The e\_assert\_wait kernel service can be called from the process environment only.

### **Related Information**

The e\_clear\_wait kernel service, e\_block\_thread kernel service, e\_sleep\_thread kernel service

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# e\_block\_thread Kernel Service

# **Purpose**

Blocks the calling kernel thread.

# **Syntax**

```
#include <sys/sleep.h>
int e_block_thread ()
```

# **Description**

The e\_block\_thread kernel service blocks the calling kernel thread. The thread must have issued a request to sleep (by calling the e assert wait kernel service). If it has been removed from its event list, it remains runnable.

### **Execution Environment**

The e\_block\_thread kernel service can be called from the process environment only.

#### **Return Values**

The e block thread kernel service return a value that indicate how the thread was awakened. The following values are defined:

THREAD AWAKENED Denotes a normal wakeup; the event occurred.

THREAD\_INTERRUPTED Denotes an interruption by a signal. THREAD\_TIMED\_OUT Denotes a timeout expiration.

THREAD\_OTHER Delineates the predefined system codes from those that need to be defined at the

subsystem level. Subsystem should define their own values greater than or equal

to this value.

### **Related Information**

The e assert wait kernel service.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# e clear wait Kernel Service

# **Purpose**

Clears the wait condition for a kernel thread.

# **Syntax**

```
#include <sys/sleep.h>
void e clear wait ( tid, result)
tid t tid;
int result;
```

#### **Parameters**

tid Specifies the kernel thread to be awakened. result

Specifies the value returned to the awakened kernel thread. The following values can be used:

#### THREAD\_AWAKENED

Usually generated by the e\_wakeup or e\_wakeup\_one kernel service to indicate a normal wakeup.

#### THREAD INTERRUPTED

Indicates an interrupted sleep. This value is usually generated by a signal delivery when the INTERRUPTIBLE flag is set.

#### THREAD TIMED OUT

Indicates a timeout expiration.

#### THREAD OTHER

Delineates the predefined system codes from those that need to be defined at the subsystem level. Subsystem should define their own values greater than or equal to this value.

# Description

The e clear wait kernel service clears the wait condition for the kernel thread specified by the tid parameter, and the thread is made runnable.

This kernel service differs from the e\_wakeup, e\_wakeup\_one, and e\_wakeup\_w\_result kernel services in the fact that it assumes the identity of the thread to be awakened. This kernel service should be used to handle exceptional cases, where a special action needs to be taken. The result parameter is used to specify the value returned to the awakened thread by the e\_block\_thread or e\_sleep\_thread kernel service.

The e\_clear\_wait kernel service has no return values.

### **Execution Environment**

The e\_clear\_wait kernel service can be called from either the process environment or the interrupt environment.

#### **Related Information**

The e\_wakeup, e\_wakeup\_one, or e\_wakeup\_w\_result kernel services, e\_block\_thread kernel servic, e\_sleep\_thread kernel service.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# e\_sleep Kernel Service

# **Purpose**

Forces the calling kernel thread to wait for the occurrence of a shared event.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/sleep.h> int e\_sleep ( event\_word, flags) tid t \*event word; int flags;

#### **Parameters**

Specifies the shared event word. The kernel uses the event\_word parameter to anchor the list of event\_word

processes sleeping on this event. The event\_word parameter must be initialized to EVENT\_NULL

before its first use.

flags Specifies the flags that control action on occurrence of signals. These flags can be found in the /usr/include/sys/sleep.h file. The flags parameter is used to control how signals affect waiting

for an event. The following flags are available to the **e\_sleep** service:

Indicates the termination of the wait for the event by an unmasked signal. The return

value is set to EVENT SIG.

**EVENT SIGWAKE** 

Indicates the termination of the event by an unmasked signal. This flag results in the transfer of control to the return from the last setimpx service with the return value set to

EINTR.

**EVENT SHORT** 

Prohibits the wait from being terminated by a signal. This flag should only be used for short, guaranteed-to-wakeup sleeps.

# **Description**

The e sleep kernel service is used to wait for the specified shared event to occur. The kernel places the current kernel thread on the list anchored by the event\_word parameter. This list is used by the e\_wakeup service to wake up all threads waiting for the event to occur.

The anchor for the event list, the event word parameter, must be initialized to **EVENT NULL** before its first use. Kernel extensions must not alter this anchor while it is in use.

The **e wakeup** service does not wake up a thread that is not currently sleeping in the **e sleep** function. That is, if an e wakeup operation for an event is issued before the process calls the e sleep service for the event, the thread still sleeps, waiting on the next e\_wakeup service for the event. This implies that routines using this capability must ensure that no timing window exists in which events could be missed due to the e\_wakeup service being called before the e\_sleep operation for the event has been called.

Note: The e sleep service can be called with interrupts disabled only if the event or lock word is pinned.

#### **Execution Environment**

The **e\_sleep** kernel service can be called from the process environment only.

#### **Return Values**

**EVENT SUCC** Indicates a successful operation.

EVENT\_SIG Indicates that the EVENT\_SIGRET flag is set and the wait is terminated by a signal.

#### **Related Information**

The **e\_sleep!** kernel service, **e\_wakeup** kernel service.

Process and Exception Management Kernel Services and Understanding Execution Environments in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# e\_sleepl Kernel Service

# **Purpose**

Forces the calling kernel thread to wait for the occurrence of a shared event.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/sleep.h> int e sleepl ( lock word, event word, flags) int \*lock word; tid t \*event word; int flags:

#### **Parameters**

lock\_word Specifies the lock word for a conventional process lock.

event\_word Specifies the shared event word. The kernel uses this word to anchor the list of kernel threads

sleeping on this event. This event word must be initialized to EVENT\_NULL before its first use.

Specifies the flags that control action on occurrence of a signal. These flags are found in the flags

/usr/include/sys/sleep.h file.

# **Description**

Note: The e\_sleepI kernel service is provided for porting old applications written for previous versions of the operating system. Use the e sleep thread kernel service when writing new applications.

The e sleepl kernel service waits for the specified shared event to occur. The kernel places the current kernel thread on the list anchored by the event\_word parameter. The e\_wakeup service wakes up all threads on the list.

The e\_wakeup service does not wake up a thread that is not currently sleeping in the e\_sleepI function. That is, if an e wakeup operation for an event is issued before the thread calls the e sleep! service for the event, the thread still sleeps, waiting on the next e\_wakeup operation for the event. This implies that routines using this capability must ensure that no timing window exists in which events could be missed due to the e\_wakeup service being called before the e\_sleepI service for the event has been called.

The e\_sleepI service also unlocks the conventional lock specified by the lock\_word parameter before putting the thread to sleep. It also reacquires the lock when the thread wakes up.

The anchor for the event list, specified by the event\_word parameter, must be initialized to EVENT\_NULL before its first use. Kernel extensions must not alter this anchor while it is in use.

Note: The e sleepl service can be called with interrupts disabled, only if the event or lock word is pinned.

#### Values for the flags Parameter

The *flags* parameter controls how signals affect waiting for an event. There are three flags available to the e\_sleepl service:

**EVENT SIGRET** Indicates the termination of the wait for the event by an unmasked signal. The return value

is set to EVENT\_SIG.

**EVENT\_SIGWAKE** Indicates the termination of the event by an unmasked signal. This flag also indicates the

transfer of control to the return from the last setimpx service with the return value set to

EINTR.

**EVENT\_SHORT** Indicates that signals cannot terminate the wait. Use the EVENT\_SHORT flag for only

short, guaranteed-to-wakeup sleeps.

Note: The EVENT SIGRET flag overrides the EVENT SIGWAKE flag.

### **Execution Environment**

The **e\_sleepl** kernel service can be called from the process environment only.

### **Return Values**

EVENT\_SUCC Indicates successful completion.

EVENT\_SIG Indicates that the EVENT\_SIGRET flag is set and the wait is terminated by a signal.

#### **Related Information**

The **e** sleep kernel service, **e** wakeup kernel service.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

Interrupt Environment in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# e\_sleep\_thread Kernel Service

# **Purpose**

Forces the calling kernel thread to wait for the occurrence of a shared event.

# **Syntax**

```
#include <sys/sleep.h>
int e_sleep_thread ( event word, lock word, flags)
tid t *event word;
void *lock word;
int flags;
```

#### **Parameters**

event\_word Specifies the shared event word. The kernel uses the event\_word parameter as the anchor to the

list of threads waiting on this shared event.

lock word Specifies simple or complex lock to unlock. Specifies lock and signal handling options. flags

# **Description**

The e\_sleep\_thread kernel service forces the calling thread to wait until a shared event occurs. The kernel places the calling thread on the event list anchored by the event word parameter. This list is used by the e wakeup, e wakeup one, and e wakeup w result kernel services to wakeup some or all threads waiting for the event to occur.

A lock can be specified; it will be unlocked when the kernel service is entered, just before the thread blocks. This lock can be a simple or a complex lock, as specified by the flags parameter. When the kernel service exits, the lock is re-acquired.

# **Flags**

The *flags* parameter specifies options for the kernel service. Several flags can be combined with the bitwise OR operator. They are described below.

The four following flags specify the lock type. If the lock\_word parameter is not NULL, exactly one of these flags must be used.

Description Flag

LOCK\_HANDLER lock\_word specifies a simple lock protecting a thread-interrupt or interrupt-interrupt critical

section.

LOCK SIMPLE lock\_word specifies a simple lock protecting a thread-thread critical section.

LOCK\_READ lock\_word specifies a complex lock in shared-read mode. LOCK\_WRITE lock\_word specifies a complex lock in exclusive write mode.

The following flag specify the signal handling. By default, while the thread sleeps, signals are held pending until it wakes up.

INTERRUPTIBLE The signals must be checked while the kernel thread is sleeping. If a signal needs to be

delivered, the thread is awakened.

#### **Return Values**

The e sleep thread kernel service return a value that indicate how the kernel thread was awakened. The following values are defined:

THREAD\_AWAKENED Denotes a normal wakeup; the event occurred.

THREAD INTERRUPTED Denotes an interruption by a signal. This value can be returned even if the

**INTERRUPTIBLE** flag is not set since it may be also generated by the

e\_clear\_wait or e\_wakeup\_w\_result kernel services.

THREAD TIMED OUT Denotes a timeout expiration. The e sleep thread has no timeout. However, the

e\_clear\_wait or e\_wakeup\_w\_result kernel services may generate this return

value.

THREAD\_OTHER Delineates the predefined system codes from those that need to be defined at the

subsystem level. Subsystem should define their own values greater than or equal

to this value.

### **Execution Environment**

The e sleep thread kernel service can be called from the process environment only.

Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

# et\_post Kernel Service

# **Purpose**

Notifies a kernel thread of the occurrence of one or more events.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/sleep.h> void et\_post ( events, tid) unsigned long events; tid t tid;

#### **Parameters**

events Identifies the masks of events to be posted.

tid Specifies the thread identifier of the kernel thread to be notified.

# **Description**

The et\_post kernel service is used to notify a kernel thread that one or more events occurred.

The et\_post service provides the fastest method of interprocess communication, although only the event numbers are passed.

The event numbers must be known by the cooperating components, either through programming convention or the passing of initialization parameters.

The et\_post service is performed automatically when sending a request to a device queue serviced by a kernel thread or when sending an acknowledgment.

The EVENT\_KERNEL mask defines the event bits reserved for use by the kernel. For example, a bit with a value of 1 indicates an event bit reserved for the kernel. Kernel extensions should assign their events starting with the most significant bits and working down. If threads using the et\_post service are also using the device gueue management kernel extensions, care must be taken not to use the event bits registered for device queue management.

The et\_wait service does not sleep but returns immediately if a specified event has already been posted by the **et post** service.

### **Execution Environment**

The et post kernel service can be called from either the process or interrupt environment.

### **Return Values**

The et\_post service has no return values.

#### **Related Information**

The et\_wait kernel service.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## et wait Kernel Service

# **Purpose**

Forces the calling kernel thread to wait for the occurrence of an event.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/sleep.h> unsigned long et\_wait ( wait\_mask, clear\_mask, flags) unsigned long wait mask; unsigned long clear mask; int flags;

#### **Parameters**

wait\_mask Specifies the mask of events to await. Specifies the mask of events to clear. clear\_mask

flags Specifies the flags controling actions on occurrence of a signal.

> The flags parameter is used to control how signals affect waiting for an event. There are two flag values:

#### **EVENT\_SIGRET**

Causes the wait for the event to be ended by an unmasked signal and the return value set to **EVENT\_SIG**.

#### **EVENT SIGWAKE**

Causes the event to be ended by an unmasked signal and control transferred to the return from the last setjmpx call, with the return value set to EXSIG.

#### **EVENT SHORT**

Prohibits the wait from being terminated by a signal. This flag should only be used for short, guaranteed-to-wakeup sleeps.

Note: The EVENT\_SIGRET flag overrides the EVENT\_SIGWAKE flag.

# **Description**

The et\_wait kernel service forces the calling kernel thread to wait for specified events to occur.

The wait\_mask parameter indicates a mask, where each bit set equal to 1 represents an event for which the thread must wait. The clear\_mask parameter indicates a mask of events that must clear when the wait is complete. Subsequent calls to the et\_wait service return immediately unless you clear the bits, which ends the wait.

Note: The et\_wait service can be called with interrupts disabled only if the event or lock word is pinned.

#### Strategies for Using et wait

Calling the et\_wait kernel service with the EVENT\_SIGRET flag clears the the pending events field when the signal is received. If et wait is called again by the same kernel thread, the thread waits indefinitely for an event that has already occurred. When this happens, the thread does not run to completion. This problem occurs only if the event and signal are posted at the same time.

To avoid this problem, use one of the following programming methods:

- Use the EVENT\_SHORT flag to prevent signals from waking the thread up.
- · Mask signals prior to the call of et wait by using the limit sigs kernel service. Then call et wait. Invoke the sigprocmask call to restore the signal mask by using the mask returned previously by limit\_sigs.

The et\_wait service is also used to clear events without waiting for them to occur. This is accomplished by doing one of the following:

- Set the wait\_mask parameter to EVENT\_NDELAY.
- Set the bits in the clear\_mask parameter that correspond with the events to be cleared to 1.

Because the et\_wait service returns an event mask indicating those events that were actually cleared, these methods can be used to poll the events.

### **Execution Environment**

The et wait kernel service can be called from the process environment only.

#### **Return Values**

Upon successful completion, the et wait service returns an event mask indicating the events that terminated the wait. If an EVENT NDELAY value is specified, the returned event mask indicates the pending events that were cleared by this call. Otherwise, it returns the following error code:

EVENT\_SIG Indicates that the EVENT\_SIGRET flag is set and the wait is terminated by a signal.

#### Related Information

The et\_post kernel service, setjmpx kernel service.

# e wakeup, e wakeup one, or e wakeup w result Kernel Service

# Purpose

Notifies kernel threads waiting on a shared event of the event's occurrence.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/sleep.h>
void e wakeup ( event word)
tid t *event word;
void e wakeup one ( event word)
tid t *event word;
void e_wakeup_w_result ( event word, result)
tid_t *event word;
int result;
```

#### **Parameters**

event\_word

Specifies the shared event designator. The kernel uses the event\_word parameter as the anchor to the list of threads waiting on this shared event.

result

Specifies the value returned to the awakened kernel thread. The following values can be used:

#### THREAD\_AWAKENED

Indicates a normal wakeup. This is the value automatically generated by the e\_wakeup or e\_wakeup\_one kernel services.

#### THREAD INTERRUPTED

Indicates an interrupted sleep. This value is usually generated by a signal delivery when the INTERRUPTIBLE flag is set.

#### THREAD TIMED OUT

Indicates a timeout expiration.

#### THREAD OTHER

Delineates the predefined system codes from those that need to be defined at the subsystem level. Subsystem should define their own values greater than or equal to this

# **Description**

The e\_wakeup and e\_wakeup\_w\_result kernel services wake up all kernel threads sleeping on the event list anchored by the event\_word parameter. The e\_wakeup\_one kernel service wakes up only the most favored thread sleeping on the event list anchored by the event word parameter.

When threads are awakened, they return from a call to either the e\_block\_thread or e\_sleep\_thread kernel service. The return value depends on the kernel service called to wake up the threads (the wake-up kernel service):

- THREAD AWAKENED is returned if the e wakeup or e wakeup one kernel service is called
- The value of the result parameter is returned if the e wakeup w result kernel service is called.

If a signal is delivered to a thread being awakened by one of the wake-up kernel services, and if the thread specified the INTERRUPTIBLE flag, the signal delivery takes precedence. The thread is awakened with a return value of THREAD\_INTERRUPTED, regardless of the called wake-up kernel service.

The e wakeup and e wakeup w result kernel services set the event word parameter to EVENT NULL.

The e wakeup, e wakeup one, and e wakeup w result kernel services have no return values.

#### **Execution Environment**

The e wakeup, e wakeup one, and e wakeup w result kernel services can be called from either the process environment or the interrupt environment.

When called by an interrupt handler, the event\_word parameter must be located in pinned memory.

#### **Related Information**

The e\_block\_thread kernel service, e\_clear\_wait kernel service, e\_sleep\_thread kernel service.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# e wakeup w sig Kernel Service

# **Purpose**

Posts a signal to sleeping kernel threads.

## **Syntax**

```
#include <sys/sleep.h>
void e wakeup w sig ( event word, sig)
tid t *event word;
int sig;
```

### **Parameters**

Specifies the shared event word. The kernel uses the event\_word parameter as the anchor to the event\_word

list of threads waiting on this shared event.

Specifies the signal number to post. sig

# **Description**

The e\_wakeup\_w\_sig kernel service posts the signal sig to each kernel thread sleeping interruptible on the event list anchored by the event word parameter.

The **e\_wakeup\_w\_sig** kernel service has no return values.

## **Execution Environment**

The e\_wakeup\_w\_sig kernel service can be called from either the process environment or the interrupt environment.

## **Related Information**

The e block thread kernel service, e clear wait kernel service.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# eeh\_broadcast Kernel Service

# **Purpose**

This service is provided for device drivers to coordinate activities during an EEH event.

# **Syntax**

```
void eeh broadcast(handle, message)
eeh handle;
unsigned long long message;
```

## **Parameters**

EEH handle obtained from eeh\_init or eeh\_init\_multifunc handle

message User- or kernel-defined message

# **Description**

Because single-function drivers do not have a need for coordination, this service is intended for multifunction drivers only. If a single-function driver calls it, it is a NOP. There are two kinds of messages that can be sent among the drivers: kernel-defined messages (such as EEH DD SUSPEND and EEH\_DD\_DEAD) and the user-defined messages. See sys/eeh.h for help on how to define user

messages. Kernel messages have a higher priority than user messages. Therefore, if user messages and kernel messages are both pending, the kernel messages are sent out before the user messages.

Note: Device drivers should only broadcast their own messages (that is, the user-defined message) and not the kernel messages.

Within the kernel messages, EEH\_DD\_DEAD has the highest priority. Multiple messages of the same kind may or may not be coalesced depending upon the relative timing. Messages are sent by invoking the callback routines. The callback routines are invoked sequentially but not in any specific order except that the last driver to receive a message will have the EEH\_MASTER flag set to indicate that all other drivers have finished processing the message. Only one message is broadcast at a time—that is, all registered callback routines are called sequentially with the same message before moving on to the next message. Finally, they are invoked asynchronously at INTIODONE priority. Because they are broadcast asynchronously, a device driver must not assume on a specific timeout within which the message would arrive.

The macro **EEH BROADCAST**(handle, message) is provided for device drivers to call this service.

#### **Execution Environment**

This kernel service can be called from the process or interrupt environment.

#### **Return Values**

This service has no return value.

#### **Related Information**

"eeh clear Kernel Service," "eeh disable slot Kernel Service" on page 127, "eeh enable dma Kernel Service" on page 128, "eeh enable pio Kernel Service" on page 129, "eeh enable slot Kernel Service" on page 130, "eeh init Kernel Service" on page 131, "eeh init multifunc Kernel Service" on page 133, "eeh\_read\_slot\_state Kernel Service" on page 135, "eeh\_reset\_slot Kernel Service" on page 137, "eeh\_slot\_error Kernel Service" on page 138

# eeh clear Kernel Service

# **Purpose**

This service unregisters a slot for an EEH function and removes resources allocated by the eeh init or eeh init multifunc kernel service.

# **Syntax**

#include <sys/eeh.h> void eeh clear(handle) eeh handle t handle;

## **Parameters**

handle EEH handle obtained from theeeh\_init or eeh\_init\_multifunc kernel services

# **Description**

Single-function Drivers: This service disables EEH function on the slot and frees its eeh\_handle.

Multifunction Drivers: For a multifunction adapter driver, this service removes the driver from a list of registered drivers under the same parent bus. This service also disables EEH function on the slot if this is the last driver to unregister and the state of the slot is NORMAL.

All device drivers are required to call **eeh\_clear** before being removed from the system, so that there are no hot plug conflicts. A subsequent adapter might fail in eeh init multifunc() on the slot if the eeh clear kernel service has not cleared the prior device drivers on that slot. A driver can unregister at unconfigure/unload time. The kernel checks the state of the slot when this service is called. If the slot state is neither NORMAL nor DEAD, eeh\_clear sleeps until the state returns to one of them.

The macro EEH\_CLEAR(handle) is provided for device drivers to call this service. This service is called by a function pointer in the EEH handle.

### **Execution Environment**

This kernel service can only be called from the process environment.

### **Return Values**

This service has no return values.

#### **Related Information**

"eeh broadcast Kernel Service" on page 125, "eeh disable slot Kernel Service," "eeh enable dma Kernel Service" on page 128, "eeh\_enable\_pio Kernel Service" on page 129, "eeh\_enable\_slot Kernel Service" on page 130, "eeh init Kernel Service" on page 131, "eeh init multifunc Kernel Service" on page 133, "eeh\_read\_slot\_state Kernel Service" on page 135, "eeh\_reset\_slot Kernel Service" on page 137, "eeh slot error Kernel Service" on page 138

## eeh disable slot Kernel Service

# **Purpose**

This service disables a slot for the EEH operations.

# **Syntax**

#include <sys/eeh.h>

long eeh disable slot(handle) eeh handle t handle;

#### **Parameters**

handle

EEH handle obtained from theeeh\_init kernel service

# **Description**

This service disables EEH operation on a slot.

#### **CAUTION:**

CAUTION: Disabling EEH operation on a slot is highly discouraged, because it can cause system crash or worse, data corruption.

This service can only be called by the single-function adapter drivers. If the service fails for a hardware or firmware reason, an error is logged.

Multifunction drivers call this service indirectly via eeh clear(). It fails with EEH FAIL if called directly by a multifunction driver.

The macro **EEH\_DISABLE\_SLOT**(handle) is provided for device drivers to call this service.

### **Execution Environment**

This kernel service can be called from the process or interrupt environment.

### **Return Values**

EEH SUCC Slot successfully disabled EEH\_FAIL Unable to disable the slot

## **Related Information**

"eeh broadcast Kernel Service" on page 125, "eeh clear Kernel Service" on page 126, "eeh enable dma Kernel Service." "eeh enable pio Kernel Service" on page 129. "eeh enable slot Kernel Service" on page 130, "eeh init Kernel Service" on page 131, "eeh init multifunc Kernel Service" on page 133, "eeh read slot state Kernel Service" on page 135, "eeh reset slot Kernel Service" on page 137, "eeh\_slot\_error Kernel Service" on page 138

## eeh enable dma Kernel Service

## **Purpose**

This service enables DMA operations to an adapter after an EEH event.

# **Syntax**

#include <sys/eeh.h>

long eeh enable dma(handle) eeh handle t handle;

#### **Parameters**

handle

EEH handle obtained from theeeh\_init or eeh\_init\_multifunc kernel services

# **Description**

When an EEH event occurs on a slot, all Direct Memory Access (DMA) operations on the slot are inhibited. This service should be called to re-enable DMA after an EEH event. This service can only be called from the dump context (that is, when the dump is in progress).

Single-function Drivers: This service enables the DMA operations on a slot. If this call fails with EEH FAIL, an error is logged by the kernel.

Multifunction Drivers: On the multifunction adapters, the slot state must be either SUSPEND or DEBUG, and the caller must be an EEH MASTER. This service is called only from a dump context. While a system dump is in progress, all callbacks and broadcasts are suspended, and a multifunction adapter is treated like a single-function adapter, because the system can no longer support the EEH multifunction kernel services. If the service fails, EEH FAIL is returned. If the failure is due to hardware or firmware, an error is logged.

There are cases when this kernel service cannot succeed because of the platform state restrictions. In such a case, if a driver calls it, the service would return EEH FAIL. This causes the slot to be marked permanently unavailable, which is not correct because the slot can be recovered. To avoid receiving EEH\_FAIL from this service, the driver should supply the EEH\_ENABLE\_NO\_SUPPORT\_RC flag at eeh\_init\_multifunc() time. If the EEH\_ENABLE\_NO\_SUPPORT\_RC flag is supplied, eeh\_enable\_dma() returns EEH NO SUPPORT, indicating to the drivers that they cannot collect debug data but must continue with the next step in recovery.

The macro **EEH\_ENABLE\_DMA**(handle) is provided for device drivers to call this service.

### **Execution Environment**

This kernel service can only be called from a process or interrupt environment.

### **Return Values**

This kernel service has no return values.

#### Related Information

"eeh\_broadcast Kernel Service" on page 125, "eeh\_clear Kernel Service" on page 126, "eeh\_disable\_slot Kernel Service" on page 127, "eeh\_enable\_pio Kernel Service," "eeh\_enable\_slot Kernel Service" on page 130, "eeh init Kernel Service" on page 131, "eeh init multifunc Kernel Service" on page 133, "eeh read slot state Kernel Service" on page 135, "eeh reset slot Kernel Service" on page 137, "eeh slot error Kernel Service" on page 138

## eeh\_enable\_pio Kernel Service

## **Purpose**

This kernel service enables programmed I/O (PIO or MMIO) to an adapter after an EEH event.

# **Syntax**

#include <sys/eeh.h>

long eeh enable pio(handle) eeh handle t handle;

#### **Parameters**

EEH handle obtained from the eeh init or eeh init multifunc kernel services handle

# **Description**

When an EEH event occurs on a slot, all load and store operations (such as PIO) are inhibited. This kernel service should be called to re-enable PIO after an EEH event.

Single-function Drivers: This kernel service enables the load and store operations on a slot. If this call fails with EEH\_FAIL, an error is logged by the kernel.

Multifunction Drivers: On the multifunction adapters, the state of the slot is checked for either SUSPEND or DEBUG. The caller must be an EEH MASTER. If the state is SUSPEND, a series of device driver callback routines is executed with a command option of EEH\_DD\_DEBUG and flag set to EEH DD PIO ENABLED. The callbacks inform device drivers that PIO has been enabled and that further debug procedures can be executed (such as reading command and status register). This service can be called as a result of the EEH DD SUSPEND or EEH DD DEBUG callback message as many times as

needed by the EEH MASTER. Additional calls to this service trigger a new set of callbacks. If this service fails, EEH FAIL is returned. If the failure is due to hardware or firmware, an error is logged.

There are cases when this kernel service cannot succeed due to the platform state restrictions. In such a case, if a driver calls it, the kernel service would return EEH FAIL followed by a EEH DD DEAD message. This causes the slot to be marked permanently unavailable, which is not correct because the slot can be recovered. To avoid receiving EEH\_FAIL from this service, the driver should supply the EEH\_ENABLE\_NO\_SUPPORT\_RC flag at eeh\_init\_multifunc() time. If the EEH\_ENABLE\_NO\_SUPPORT\_RC flag is supplied, eeh\_enable\_pio() returns EEH\_NO\_SUPPORT, indicating to the drivers that they cannot collect debug data but must continue with the next step in recovery.

The macro EEH\_CLEAR(handle) is provided for device drivers to call this service. This service is called via a function pointer in the EEH handle.

Note: Enabling PIO is not the same as recovering the slot. In fact, this is an optional step in the recovery procedure.

### **Execution Environment**

This kernel service can be called from the process or interrupt environment.

### **Return Values**

**EEH SUCC** PIO successfully enabled.

EEH\_FAIL Invalid call or could not enable PIO.

Call is valid according to AIX® EEH state, but current platform state precludes EEH\_NO\_SUPPORT

normal completion.

#### **Related Information**

# eeh\_enable\_slot Kernel Service

# **Purpose**

This service enables a slot for the EEH operations.

# **Syntax**

#include <sys/eeh.h>

long eeh enable slot(handle) eeh\_handle\_t handle;

#### **Parameters**

handle EEH handle obtained from theeeh init kernel service

## **Description**

This service enables EEH operation on a slot so that when certain errors occur on a PCI bus, the slot will freeze (that is, PIO and DMA are disabled, which prevents potential system crash, data corruption, and so on). This service can only be called by the single-function adapter drivers. If the service fails for hardware or firmware reasons, an error is logged.

Multifunction drivers call this service indirectly via eeh\_init\_multifunc(). It fails with EEH\_FAIL if called directly by a multifunction driver.

The macro **EEH\_ENABLE\_SLOT**(handle) is provided for device drivers to call this service.

### **Execution Environment**

This kernel service can be called from the process or interrupt environment.

### **Return Values**

EEH\_SUCC Slot successfully enabled EEH\_FAIL Unable to enable the slot

#### **Related Information**

"eeh broadcast Kernel Service" on page 125, "eeh clear Kernel Service" on page 126, "eeh disable slot Kernel Service" on page 127, "eeh\_enable\_dma Kernel Service" on page 128, "eeh\_enable\_pio Kernel Service" on page 129, "eeh init Kernel Service," "eeh init multifunc Kernel Service" on page 133, "eeh\_read\_slot\_state Kernel Service" on page 135, "eeh\_reset\_slot Kernel Service" on page 137, "eeh\_slot\_error Kernel Service" on page 138

# eeh init Kernel Service

# Purpose

This service registers a single-function adapter slot on a PCI/PCI-E bus for EEH function.

# **Syntax**

```
#include <sys/eeh.h>
eeh handle t eeh init(pbid, slot, flag)
long
        pbid;
long
         slot;
long
         flag;
```

#### **Parameters**

AIX® parent bus identifier pbid

device slot (device\*8+function). This is same as "connwhere" property in CuDv. slot

flag flag that enables eeh

# **Description**

The pbid argument identifies a bus type and number. The bus type is IO\_PCI in the case of PCI and PCI-X bus. If the bus type is IO\_PCIE, the device is on PCI-E (PCI Express) bus. The bus number is a unique identifier determined during bus configuration. The BID\_VAL macro defined in ioacc.h is used to generate the bid. The slot argument is the device/function combination ((device\*8) + function) as in the

PCI addressing scheme. The flag argument of EEH\_ENABLE enables the slot. The flag argument of EEH DISABLE does not enable the slot but still allocates an EEH handle. This service should be called only by the single-function adapter drivers.

The macro **EEH\_INIT**(pbid, slot, flag) is provided for the device drivers to call this service. The **eeh handle** is defined as follows in <sys/eeh.h>:

```
* This is the eeh handle structure for the eeh * services
typedef struct eeh handle *
                                  eeh handle t;
struct eeh handle {
        struct eeh handle *next;
        long
                bid;
                                        /* bus id passed to eeh init
        long
                slot;
                                       /* slot passed to eeh init
                                                                        */
        long
                flag;
                                       /* flag passed to eeh init
                                                                        */
                                    /* Configuration Space Address */
                config addr;
        int
                                      /* Indicates safe mode
        int
                eeh mode;
                                                                        */
                                      /* re-read the slot state after *
        uint
                retry delay;
                                        * these many seconds.
        int
                reserved1;
               reserved2;

# eeh\_init\_multifunc Kernel Service

## **Purpose**

This kernel service registers a multifunction adapter slot on a PCI/PCI-E bus for EEH function.

## **Syntax**

```
#include <sys/eeh.h>
eeh handle t eeh init multifunc(gpbid, pbid, slot, flag, delay seconds,
                                callback_ptr, dds_ptr)
long gpbid;
long pbid;
long slot;
long flag;
long delay seconds;
long (*callback ptr)();
void *dds ptr;
```

### **Parameters**

gpbid Bus identifier of grandparent bus. pbid Bus identifier of parent bus.

slot Slot on the parent bus (device\*8+function). This is same as "connwhere" property in

CuDv for the device.

flaa Flag that enables eeh, checks if the slot is already taken, etc.

Time delay after a reset (in seconds). delay\_seconds callback\_ptr Device driver callback routine.

dds\_ptr Cookie to a target device driver that is usually a pointer to the adapter structure.

# **Description**

This kernel service is provided for systems that support shared EEH domain, where one or more PCI functions in one or more adapters could belong to the same EEH recovery domain. In the past, this was called "multifunction adapter". The shared EEH domain is a more general concept than just a multifunction adapter. It is also recommended that single function adapters use the shared EEH model, All PCI-E devices, single or multifunction have to use the shared EEH model and hence this kernel service to register for EEH (instead of eeh init()). In a shared EEH domain, multiple instances of device drivers may be operating. The instances are independent of each other and hence oblivious to each other's existence. Therefore, when recovering a slot from an EEH event, there is a need to coordinate the recovery procedure among them. As with eeh\_init(), this service also returns an eeh\_handle to the calling device driver.

There are two kinds of adapters: bridged and non-bridged. A bridged adapter has a bridge on the card such as PCI-to-PCI or PCIX-to-PCIX or PCI-E switch. For PCI and PCI-X bridged-adapters, pbid is the bus ID of the parent bus, and gpbid is the bus ID of the grandparent bus. The parent bus for a bridged adapter is the bus generated by the bridge/switch on the adapter. A bid identifies a bus number and type. The bus type is IO\_PCI in the case of PCI and PCI-X bus, and IO\_PCIE in the case of PCI-E bus. The bus number is a unique identifier determined during bus configuration. The BID VAL macro defined in ioacc.h is used to generate the bid. For non-bridged adapters, pbid and gpbid are the same and are the bus IDs of the parent bus. Thus, when pbid and gpbid have different values for a PCI or PCI-X device, the kernel knows that this is a bridged adapter and needs to the bridge recovered as part of EEH recovery. It is not necessary to know if a PCI-E device is bridged or not for the purposes of EEH. Therefore, pbid and applid must be same and equal to the parent bus bid.

In summary, there are the following cases:

- 1. PCI/PCI-X non-bridged adapters and all PCI-E adapters: gpbid and pbid are same and equal to the parent bus bid.
- 2. PCI/PCI-X bridged adapters, *gpbid* is grandparent bus bid, and pbid is parent bus bid.

The slot argument is the device/function combination ((device\* 8) + function) as in the PCI addressing scheme. This is the same as the connwhere ODM value of the device.

The following flag values are legal:

EEH\_ENABLE\_FLAG/EEH\_DISABLE\_FLAG

**EEH CHECK SLOT** 

EEH\_ENABLE\_NO\_SUPPORT\_RC

The slot is always enabled for EEH when this service is called by the first driver on that slot. All subsequent requests to enable the slot via the EEH\_ENABLE flag are ignored. Therefore, the flag argument of EEH\_ENABLE is optional, and a flag of **EEH\_DISABLE** is ignored. The flag argument of **EEH\_CHECK\_SLOT** verifies whether a given slot is already registered. A value of either EEH SLOT ACTIVE or EEH SLOT FREE is returned. No registration occurs with the EEH\_CHECK\_SLOT flag, and it supersedes all other flags. This flag simply checks the slot and returns without any other action. If the flag is set to EEH\_ENABLE\_NO\_SUPPORT\_RC, eeh\_enable\_pio() and eeh\_enable\_dma() return EEH NO SUPPORT under certain conditions. See "eeh\_enable\_dma Kernel Service" on page 128 and "eeh enable pio Kernel Service" on page 129 for more information.

Multiple flags can be logically ORed together.

The slot is always enabled for EEH when this service is called by the first driver on that slot. All subsequent requests to enable the slot via the EEH\_ENABLE flag are ignored. Therefore, the flag argument of EEH\_ENABLE is optional, and a flag of EEH\_DISABLE is ignored. The flag argument of EEH CHECK SLOT verifies whether a given slot is already registered. A value of either EEH SLOT ACTIVE or EEH SLOT FREE is returned. No registration will occur with the EEH CHECK SLOT flag, and it supersedes all other flags. This flag just checks the slot and returns without any other action. If the flag is set to EEH\_ENABLE\_NO\_SUPPORT\_RC, eeh\_enable\_pio() and eeh\_enable\_dma() returns EEH\_NO\_SUPPORT under certain conditions. See eeh enable pio() and eeh enable dma() for more information. It is allowed to logically OR multiple flags together.

The delay seconds argument allows the device driver to set a time delay between completion of PCI reset and configuration of the bridge on the adapter. The delay is enforced even if the adapter is non-bridged. If a value of 0 is specified for *delay\_seconds*, a default delay time of 1 second is set. When several drivers register on the same pbid (under a shared EEH domain), the highest delay time among all registered drivers is used.

The callback ptr argument is a function pointer to an EEH callback routine. The handler is defined by the device driver and is called by the kernel in order to coordinate recovery among different drivers on the same slot. The driver handles a variety of messages from the kernel in its callback routine. These messages trigger the next step in recovery. The callback routines are called sequentially at INTIODONE interrupt level.

The dds\_ptr argument is a cookie that is passed to the driver when the callback routine is invoked. Drivers normally specify a pointer to the device driver's adapter structure.

**EEH SAFE mode:** A bridged adapter needs to have its bridge reconfigured at the end of PCI reset. However, if the platform firmware does not support reconfiguration of the bridge, the adapter is marked as EEH SAFE by the kernel. An EEH SAFE adapter cannot finish error recovery after an EEH event because of the unsatisfied firmware dependency. See eeh reset slot for information on how the error recovery is handled in EEH\_SAFE mode.

The macro EEH\_INIT\_MULTIFUNC(gpbid, pbid, slot, flag, delay\_seconds, callback\_ptr, dds\_ptr) is provided for the device drivers in order to call this service. This is an exported kernel service.

### **Execution Environment**

This kernel service can only be called from the process environment.

### **Return Values**

EEH FAIL Unable to allocate EEH handle.

EEH\_NO\_SUPPORT EEH is not supported on this system, no handle allocated.

EEH\_SLOT\_ACTIVE Given slot is already registered.

EEH\_SLOT\_FREE Given slot free.

EEH BUSY Unable to continue, because the slot is in the middle of error recovery.

struct eeh\_handle \* Upon Success.

# eeh read slot state Kernel Service

# Purpose

This service returns state and capabilities of a slot with respect to EEH operation.

# **Syntax**

long eeh read slot state(handle, state, support) eeh handle t handle; long \*state; long \*support;

#### **Parameters**

EEH handle obtained from eeh\_init or eeh\_init\_multifunc handle

state State of a slot with respect to EEH support Indicates if EEH is supported by this slot

# **Description**

This service is used to query the hardware state of a slot and to determine whether a given slot supports EEH. It should be called to confirm an EEH event if the driver suspects that the PIO data is invalid (for example, getting all Fs from reading a register). This service returns the hardware state in state and indicates whether the slot supports EEH in support. The state and support parameters are integer values as shown below:

Valid state values are as follows:

EEH\_NSTOPPED\_RST\_DEA EEH\_NSTOPPED\_RST\_ACT EEH\_STOPPED\_LS\_DIS

EEH\_STOPPED\_LS\_ENA

EEH\_UNAVAILABLE

Reset deactivated and adapter is not in stopped state.
Reset activated and adapter is not in stopped state.
Adapter in stopped state with reset signal deactivated and Load/Store disabled.

Adapter in stopped state with reset signal deactivated and Load/Store enabled.

Adapter is either permanently or temporarily unavailable.

Valid *support* values are as follows:

0 EEH not supported. 1 EEH supported.

The driver should call this service and check for EEH\_STOPPED\_LS\_DIS and EEH\_STOPPED\_LS\_ENA as the *state* values if it suspects an EEH event on the adapter. If the *state* is either of those values, the slot is said to be frozen.

**Single-function Driver:** A single-function adapter driver calls this service to query the state of the slot. If the service fails due to hardware or firmware reasons, an error is logged. If the service fails, *state* and *support* values are undefined, and EEH FAIL is returned.

Multifunction Driver: For a multifunction adapter driver, this service analyzes the state to determine if:

- · The state is frozen, or
- it is permanently unavailable (that is, the slot is unusable from hereon), or
- it is temporarily unavailable.

If the slot is in either a frozen or temporarily unavailable state, the EEH\_DD\_SUSPEND message is broadcast to all registered drivers on this slot. If the slot is permanently unavailable (that is, dead), the EEH\_DD\_DEAD message is broadcast. Upon receiving this message, the drivers are expected to suspend all further DMA, PIO, interrupt, configuration cycles, and so on until the slot is recovered. If the service fails due to hardware or firmware reasons, an error is logged, EEH\_DD\_DEAD is broadcast, and EEH\_FAIL is returned.

#### Temporarily versus permanently unavailable state

In addition to *state* and *support*, this service also returns a valid *retry\_delay* value in the **eeh\_handle** structure if the *state* is EEH\_UNAVAILABLE. If *retry\_delay* is 0, it is permanently unavailable. If *retry\_delay* is non-zero, it is temporarily unavailable. A permanently unavailable state means that the slot is unusable until a hot-plug operation or partition reboot is performed. Therefore, the drivers mark their adapters as unusable when they receive an EEH\_UNAVAILABLE message (single-function) or when they receive an EEH\_DD\_DEAD message (multifunction). A temporarily unavailable state means that the current *state* of a slot is transient and might take a few minutes to settle down. Until that time, the device driver cannot begin recovery because it does not know what the final state will be. The temporarily unavailable state is handled differently by the single-function and multifunction drivers as follows:

**Single-function Driver:** Because a single-function driver drives its own recovery, it needs to check for *retry\_delay* if the *state* is set to EEH\_UNAVAILABLE. If *retry\_delay* is non-zero, it represents the number of seconds that the driver should wait before calling this kernel service again. It continues to call this service repeatedly as long as the *state* is EEH\_UNAVAILABLE and *retry\_delay* is non-zero. Eventually, the *state* will end up in one of the following:

- EEH\_NSTOPPED\_RST\_ACT
- · EEH STOPPED LS DIS
- EEH UNAVAILABLE w/ "retry delay" set to 0 (i.e. permanently unavailable)

At that point, the driver can continue with its normal course of action for a given state.

Multifunction Driver: A multifunction driver does not need to check for the retry\_delay field when the state is EEH\_UNAVAILABLE, because EEH\_UNAVAILABLE would only mean permanently unavailable. In the case of temporarily unavailable, a multifunction driver would receive the EEH DD SUSPEND or EEH DD DEAD message after some time, depending upon the final state of the slot. If the final state was EEH\_NSTOPPED\_RST\_ACT or EEH\_STOPPED\_LS\_DIS, then EEH\_DD\_SUSPEND is broadcast; if it was EEH UNAVAILABLE, then EEH DD DEAD is broadcast. Thus, from the point-of-view of a multifunction driver, there is no difference between frozen and temporarily unavailable.

The macro **EEH READ SLOT STATE**(handle, state, support) is provided for device drivers to call this service.

## **Execution Environment**

This kernel service can be called from the process or interrupt environment.

### **Return Values**

EEH SUCC Successfully read the slot state and capabilities EEH\_FAIL Unable to read the slot state and capabilities

### **Related Information**

"eeh broadcast Kernel Service" on page 125, "eeh\_clear Kernel Service" on page 126, "eeh\_disable\_slot Kernel Service" on page 127, "eeh\_enable\_dma Kernel Service" on page 128, "eeh\_enable\_pio Kernel Service" on page 129, "eeh\_enable\_slot Kernel Service" on page 130, "eeh\_init Kernel Service" on page 131, "eeh init multifunc Kernel Service" on page 133, "eeh reset slot Kernel Service." "eeh slot error Kernel Service" on page 138

## eeh reset slot Kernel Service

# Purpose

This service activates, deactivates, or toggles the reset line of a PCI slot.

# **Syntax**

#include <sys/eeh.h>

long eeh\_reset\_slot(handle, flag) eeh handle t handle; long flag;

### **Parameters**

handle EEH handle obtained from the**eeh\_init** or **eeh\_init\_multifunc** kernel services

Flag can be either EEH\_ACTIVE or EEH\_DEACTIVE. flag

# **Description**

Single-function Drivers: This service activates and deactivates the reset line between the Terminal Bridge and the adapter. The flag argument specifies whether to activate (EEH\_ACTIVE) or deactivate (EEH DEACTIVE) depending upon the required action. To do the reset of a slot, the reset line should be toggled by calling this service twice: once with EEH ACTIVE followed by a second call with

EEH DEACTIVE. There should be a minimum of 100 milliseconds delay between the activation and deactivation of the signal. The minimum delay is specified by the PCI System Architecture and should be enforced by the single-function driver.

Multifunction Drivers: On a multifunction adapter, the EEH MASTER for the slot drives error recovery. Therefore, only the EEH MASTER can call this service. Unlike the single-function driver, the master calls this service only once with the EEH\_ACTIVE flag.

For the multi-function drivers, the service first activates and then deactivates the reset signal on the slot. It enforces a 100-millisecond delay between the activation and deactivation as mandated by the PCI System Architecture. After the reset signal is deactivated, the service attempts to reconfigure the bridge on the adpater, if there is one (only applies to the bridged-adapters), after dd trb timer seconds specified in eeh\_init\_multifunc(). At the end of a successful reset and optional bridge recovery, an EEH\_DD\_RESUME message is broadcast to the slot's multifunction drivers notifying them to resume normal operation. If this service fails, the EEH\_DD\_DEAD message is broadcast. If failure is due to hardware or firmware, an error is logged.

**EEH SAFE mode:** If an EEH SAFE adapter calls this service, the reset signal is activated but is never deactivated, thereby leaving the adapter in a "permanently unavailable" state. Such an adapter becomes available again if either the PCI hot-plug operation is performed on it or if the partition is rebooted. This service returns EEH FAIL for an EEH SAFE driver.

The macro **EEH\_RESET\_SLOT**(handle, flag) is provided for device drivers to call this service.

## **Execution Environment**

This kernel service can be called from the process or interrupt environment.

## Return Values

EEH SUCC Slot reset activate/deactivate succeeded

EEH\_FAIL Failed to activate/deactivate the reset line, nonmaster called the service, or

EEH\_SAFE mode is active

EEH\_BUSY Recovery is already in progress

#### **Related Information**

"eeh\_broadcast Kernel Service" on page 125, "eeh\_clear Kernel Service" on page 126, "eeh\_disable\_slot Kernel Service" on page 127, "eeh enable dma Kernel Service" on page 128, "eeh enable pio Kernel Service" on page 129, "eeh\_enable\_slot Kernel Service" on page 130, "eeh\_init Kernel Service" on page 131, "eeh init multifunc Kernel Service" on page 133, "eeh read slot state Kernel Service" on page 135, "eeh slot error Kernel Service"

## eeh\_slot\_error Kernel Service

# **Purpose**

This service logs a temporary or permanent error and optionally marks the slot permanently unavailable.

# **Syntax**

```
#include <sys/eeh.h>
long eeh slot error(handle, flag, dd buf, dd buf length)
eeh handle t handle;
```

flag; int char \*dd buf; lona dd buf length;

### **Parameters**

handle EEH handle obtained from eeh\_init or eeh\_init\_multifunc

EEH\_RESET\_TEMP or EEH\_RESET\_PERM flag dd buf Address of the device driver's error log buffer dd\_buf\_length Length of device driver's error log buffer in bytes

## **Description**

This service performs a number of tasks:

- · It collects hardware data to help in understanding the nature and source of an EEH event
- It combines the device-driver-supplied debug data log with the hardware data log and creates an entry in the error log
- It optionally marks the slot permanently unavailable so that subsequent eeh read slot state() calls return EEH\_UNAVAILABLE with a retry\_delay value of 0

The behavior of this kernel service is controlled by two *flag* values:

This flag performs only the first two of the preceding tasks.. EEH\_RESET\_TEMP

EEH\_RESET\_PERM This flag performs all three tasks.

Depending on the hardware state of the slot, this service might not be able to collect the hardware data. Thus, the service succeeds but logs no data. If EEH RESET PERM was supplied, it still marks the slot permanently unavailable.

The dd buf and dd buf length parameters are used to combine the device driver error log with the hardware log. The dd buf argument is the address of an error log buffer containing the device driver's data. The dd buf length argument is the length of this buffer. If the length exceeds 1024 bytes in AIX® 5.1/AIX® 5.2 and MAX DD LOG SIZE bytes in AIX® 5.3 and above, the driver's log data will be truncated. If dd buf is NULL, the error log will only contain hardware data, if any.

Single-function Driver: The kernel service works as in the preceding description. If it fails because of hardware or firmware reasons, EEH FAIL is returned and an error is logged.

Multifunction Driver: For the multifunction drivers, this service works as in the preceding description, except that if EEH\_RESET\_PERM was supplied, the EEH\_DD\_DEAD message is broadcast.

The macro EEH\_SLOT\_ERROR(handle, flag, dd\_buf, dd\_buf\_length) is provided for device drivers to call this service.

### **Execution Environment**

This kernel service can be called from the process or interrupt environment.

#### **Return Values**

EEH SUCC Successfully logged error

EEH\_FAIL Failed to log the error and optionally mark the slot permanently unavailable

### **Related Information**

"eeh broadcast Kernel Service" on page 125, "eeh\_clear Kernel Service" on page 126, "eeh\_disable\_slot Kernel Service" on page 127, "eeh\_enable\_dma Kernel Service" on page 128, "eeh\_enable\_pio Kernel Service" on page 129, "eeh\_enable\_slot Kernel Service" on page 130, "eeh\_init Kernel Service" on page 131, "eeh\_init\_multifunc Kernel Service" on page 133, "eeh\_read\_slot\_state Kernel Service" on page 135, "eeh reset slot Kernel Service" on page 137

## enque Kernel Service

## **Purpose**

Sends a request queue element to a device queue.

# **Syntax**

#include <svs/tvpes.h> #include <sys/errno.h> #include <sys/deviceq.h> int enque ( ge) struct req qe \*qe;

### **Parameter**

Specifies the address of the request queue element.

# **Description**

The enque kernel service is not part of the base kernel, but is provided by the device queue management kernel extension. This queue management kernel extension must be loaded into the kernel before loading any kernel extensions referencing these services.

The **enque** service places the queue element into a specified device queue. It is used for simple process-to-process communication within the kernel. The requester builds a copy of the queue element. indicated by the ge parameter, and passes this copy to the enque service. The kernel copies this queue element into a queue element in pinned global memory and then enqueues it on the target device queue.

The path identifier in the request gueue element indicates the device gueue into which the element is placed.

The **enque** service supports the sending of the following types of queue elements:

Queue Element Description SEND CMD Send command. START\_IO Start I/O.

GEN PURPOSE General purpose.

For simple interprocess communication, general purpose queue elements are used.

The queue element priority value can range from QE\_BEST\_PRTY to QE\_WORST\_PRTY. This value is limited to the value specified when the queue was created.

The operation options in the queue element control how the queue element is processed. There are five standard operation options:

**Operation Option** Description

ACK\_COMPLETE Acknowledge completion in all cases.

**ACK ERRORS** Acknowledge completion if the operation results in an error.

SYNC REQUEST Synchronous request. CHAINED Chained control blocks. CONTROL\_OPT Kernel control operation.

Note: Only one of ACK COMPLETE, ACK ERRORS, or SYNC REQUEST can be specified. Also, all of these options are ignored if the path specifies that no acknowledgment (NO ACK) should be sent.

With the SYNC\_REQUEST synchronous request option, control does not return from the enque service until the request queue element is acknowledged. This performs in one step what can also be achieved by sending a queue element with the ACK\_COMPLETE flag on, and then calling either the et\_wait or waitq kernel services.

The kernel calls the server's **check** routine, if one is defined, before a queue element is placed on the device queue. This routine can stop the operation if it detects an error.

The kernel notifies the device queue's server, if necessary, after a queue element is placed on the device queue. This is done by posting the server process (using the et\_post kernel service) with an event control bit.

## **Execution Environment**

The **enque** kernel service can be called from the process environment only.

## **Return Values**

RC GOOD Indicates a successful operation.

RC\_ID Indicates a path identifier that is not valid.

All other error values represent errors returned by the server.

#### Related Information

The et\_post kernel service, et\_wait kernel service, waitq kernel service.

The **check** device queue management routine.

### errresume Kernel Service

## Purpose

Resumes error logging after an **errlast** command was issued.

# **Syntax**

void errresume()

# **Description**

When an error is logged with the errlast command, no more error logging will happen on the system until an errresume call is issued.

## **Execution Environment**

This can be called from either the process or an interrupt level.

#### **Related Information**

The "errsave or errlast Kernel Service."

Error-Logging Facility in AIX® Version 7.1 General Programming Concepts: Writing and Debugging **Programs** 

### errsave or errlast Kernel Service

# **Purpose**

Allows the kernel and kernel extensions to write to the error log.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/errids.h> void errsave ( buf, cnt) char \*buf; unsigned int cnt; void errlast (buf, cnt) char \*buf unsigned int cnt;

### **Parameters**

cnt

huf Points to a buffer that contains an error record as described in the /usr/include/sys/err\_rec.h file.

Specifies the number of bytes in the error record contained in the buffer pointed to by the buf parameter.

# **Description**

The errsave kernel service allows the kernel and kernel extensions to write error log entries to the error device driver. The error record pointed to by the buf parameter includes the error ID resource name and detailed data.

In addition, the errlast kernel service disables any future error logging, thus any error logged with errlast will stay on NVRAM. This service is only for use prior to a pending system crash or stop. The errlast service should only be used in extreme circumstances where the system can not continue, such as the occurance of a machine check.

#### **Execution Environment**

The errsave kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The errsave service has no return values.

#### **Related Information**

The errlog subroutine.

For more information on error device drivers, see Error Logging Special Files in AIX® Version 7.1 Files Reference.

## fetch\_and\_add Kernel Services

## **Purpose**

Increments a variable atomically.

## **Syntax**

```
#include <sys/atomic_op.h>
int fetch_and_add (addr, value)
atomic p addr;
int value:
long fetch_and_addlp (addr, value)
atomic_1 addr;
long value;
```

#### **Parameters**

addr Specifies the address of the variable to be incremented. value Specifies the value to be added to the variable.

# **Description**

The **fetch and add** kernel services atomically increment a variable.

The fetch\_and\_add kernel service operates on a single word (32 bit) variable while the fetch\_and\_addlp kernel service operates on a double word (64 bit) variable.

These operations are useful when a counter variable is shared between several kernel threads, because it ensures that the fetch, update, and store operations used to increment the counter occur atomically (are not interruptible).

### Note:

- The single word variable for the fetch\_and\_add kernel service must be aligned on a word (32 bit) boundary.
- The double word variable for the **fetch\_and\_addlp** kernel service must be aligned on a double word (64 bit) boundary.

### **Execution Environment**

The **fetch\_and\_add** kernel services can be called from either the process or interrupt environment.

### **Return Values**

The **fetch\_and\_add** kernel services return the original value of the variable.

### **Related Information**

The fetch\_and\_and kernel service, fetch\_and\_or kernel service, compare\_and\_swap kernel service.

Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

# fetch and and or fetch and or Kernel Services

## **Purpose**

Clears and sets bits in a variable atomically.

## **Syntax**

```
#include <sys/atomic op.h>
uint fetch_and_and (addr, mask)
atomic_p addr;uint mask;
ulong fetch and andlp (addr, mask)
atomic 1 addr;
ulong mask;
uint fetch_and_or (addr, mask)
atomic_p addr;
uint mask;
ulong fetch and orlp (addr, mask)
atomic 1 addr;
ulong mask;
```

### **Parameters**

addr Specifies the address of the variable whose bits are to be cleared or set.

mask Specifies the bit mask which is to be applied to the variable.

# **Description**

The **fetch and and** and **fetch and or** kernel services respectively clear and set bits in a variable, according to a bit mask, as a single atomic operation. The fetch and and service clears bits in the variable which correspond to clear bits in the bit mask, and the fetch and or service sets bits in the variable which correspond to set bits in the bit mask.

The fetch and add and fetch and or kernel services operate on a single word (32 bit) variable while the fetch and addlp and fetch and orlp kernel services operate on a double word (64 bit) variable.

These operations are useful when a variable containing bit flags is shared between several kernel threads, because they ensure that the fetch, update, and store operations used to clear or set a bit in the variable occur atomically (are not interruptible).

#### Note:

- For the fetch and and fetch and or kernel services, the single word containing the bit flags must be aligned on a full word (32 bit) boundary.
- For the fetch\_and\_addlp and fetch\_and\_orlp kernel services, the double word containing the bit flags must be aligned on a double word (64 bit) boundary.

#### **Execution Environment**

The fetch\_and\_and and fetch\_and\_or kernel services can be called from either the process or interrupt environment.

## **Return Values**

The **fetch\_and\_and** and **fetch\_and\_or** kernel services return the original value of the variable.

#### **Related Information**

The **fetch** and add kernel service, **compare** and **swap** kernel service.

Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

## fidtovp Kernel Service

## **Purpose**

Maps a file system structure to a file ID.

Maps a file identifier to a mode.

## **Syntax**

#include <sys/types.h> #include <sys/vnode.h> int fidtovp(fsid, fid, vpp) fsid\_t \*fsid; struct fileid \*fid; struct vnode \*\*vpp;

## **Parameters**

fsid Points to a file system ID structure. The system uses this structure to determine which virtual file system (VFS) contains the requested file.

Points to a file ID structure. The system uses this pointer to locate the specific file within the VFS. fid

Points to a location to store the file's vnode pointer upon successful return of the fidtovp kernel service.

# **Description**

The fidtovp kernel service returns a pointer to a vnode for the file identified by fsid and fid, and increments the count on the vnode so the file is not removed. Subroutines that call the fidtovp kernel service must call VNOP\_RELE to release the vnode pointer.

This kernel service is designed for use by the server side of distributed file systems.

#### **Execution Environment**

The **fidtovp** kernel service can be called from the process environment only.

### **Return Values**

Indicates successful completion.

**ESTALE** Indicates the requested file or file system was removed or recreated since last access with the given file system ID or file ID.

# find\_input\_type Kernel Service

## **Purpose**

Finds the given packet type in the Network Input Interface switch table and distributes the input packet according to the table entry for that type.

## **Syntax**

#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>
int find\_input\_type (type, m, ac, header\_pointer)
ushort type;
struct mbuf \* m;
struct arpcom \* ac;
caddr\_t header\_pointer;

## **Parameters**

type Specifies the protocol type.

m Points to the **mbuf** buffer containing the packet to distribute.

ac Points to the network common portion (arpcom) of the network interface on which the

packet was received. This common portion is defined as follows:

in net/if arp.h

header\_pointer Points to the buffer containing the input packet header.

## **Description**

The **find\_input\_type** kernel service finds the given packet type in the Network Input table and distributes the input packet contained in the **mbuf** buffer pointed to by the *m* value. The *ac* parameter is passed to services that do not have a queued interface.

#### **Execution Environment**

The **find\_input\_type** kernel service can be called from either the process or interrupt environment.

### **Return Values**

Indicates that the protocol type was successfully found.

**ENOENT** Indicates that the service could not find the type in the Network Input table.

## **Related Information**

The add\_input\_type kernel service, del\_input\_type kernel service.

Network Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_access Kernel Service

# **Purpose**

Checks for access permission to an open file.

## **Syntax**

#include <sys/types.h> #include <sys/errno.h> int fp\_access (fp, perm) struct file \*fp; int perm;

### **Parameters**

Points to a file structure returned by the fp\_open or fp\_opendev kernel service.

perm Indicates which read, write, and execute permissions are to be checked. The /usr/include/sys/mode.h file contains pertinent values (IREAD, IWRITE, IEXEC).

# **Description**

The fp\_access kernel service is used to see if either the read, write, or exec bit is set anywhere in a file's permissions mode. Set *perm* to one of the following constants from **mode.h**:

**IREAD IWRITE IEXEC** 

## **Execution Environment**

The **fp\_access** kernel service can be called from the process environment only.

## **Return Values**

Indicates that the calling process has the requested permission.

**EACCES** Indicates all other conditions.

### **Related Information**

The access subroutine.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_close Kernel Service

# **Purpose**

Closes a file.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> int fp\_close ( fp) struct file \*fp;

### **Parameter**

Points to a file structure returned by the fp\_open, fp\_getf, or fp\_opendev kernel service.

# **Description**

The fp close kernel service is a common service for closing files used by both the file system and routines outside the file system.

### **Execution Environment**

The **fp\_close** kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful operation.

If an error occurs, one of the values from the /usr/include/sys/error.h file is returned.

### **Related Information**

The close subroutine.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_close Kernel Service for Data Link Control (DLC) Devices

## **Purpose**

Allows kernel to close the generic data link control (GDLC) device manager using a file pointer.

# **Syntax**

int fp\_close( fp)

### **Parameters**

fp

Specifies the file pointer of the GDLC being closed.

# **Description**

The fp\_close kernel service disables a GDLC channel. If this is the last channel to close on a port, the GDLC device manager resets to an idle state on that port and the communications device handler is closed. The **fp\_close** kernel service may be called from the process environment only.

#### **Return Values**

**ENXIO** 

Indicates a successful completion.

Indicates an invalid file pointer. This value is defined in the

/usr/include/sys/errno.h file.

## **Related Information**

The fp\_close kernel service.

The **fp\_open** kernel service for data link control (DLC) devices.

Generic Data Link Control (GDLC) Environment Overview in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_fstat Kernel Service

## **Purpose**

Gets the attributes of an open file.

## **Syntax**

#include <sys/types.h> #include <sys/errno.h> int fp\_fstat (fp, statbuf, statsz, segflag) struct file \* fp; caddr\_t statbuf; unsigned int statsz; unsigned int segflag;

### **Parameters**

fp Points to a file structure returned by the fp\_open kernel service.

statbuf Points to a buffer defined to be of stat or fullstat type structure. The statsz parameter indicates the

buffer type.

statsz Indicates the size of the stat or fullstat structure to be returned. The /usr/include/sys/stat.h file

contains information about the stat structure.

segflag Specifies the flag indicating where the information represented by the statbuf parameter is located:

SYS ADSPACE

Buffer is in kernel memory.

USER\_ADSPACE

Buffer is in user memory.

# **Description**

The fp fstat kernel service is an internal interface to the function provided by the fstatx subroutine.

## **Execution Environment**

The fp\_fstat kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

If an error occurs, one of the values from the /usr/include/sys/errno.h file is returned.

#### **Related Information**

The fstatx subroutine.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_fsync Kernel Service

# **Purpose**

Writes changes for a specified range of a file to permanent storage.

## **Syntax**

```
#include <sys/fp_io.h>
int fp fsync (fp, how, off, len)
struct file *fp;
int how;
offset_t off;
offset_t len;
```

## **Description**

The fp\_fsync kernel service is an internal interface to the function provided by the fsync\_range subroutine.

## **Parameters**

fp Points to a file structure returned by the **fp\_open** kernel service.

how How to flush, FDATASYNC, or FFILESYNC:

**FDATASYNC** 

Write file data and enough of the meta-data to retrieve the data for the specified range.

**FFILESYNC** 

All modified file data and meta-data for the specified range.

off Starting file offset.

len Length, or zero for everything

### **Execution Environment**

The **fp fsync** kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

**ERRNO** Returns an error number from the /usr/include/sys/

errno.h file on failure.

## **Related Information**

The fsync or fsync range Subroutine in AIX® Version 7.1 Technical Reference: Base Operating System and Extensions, Volume 1.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_getdevno Kernel Service

# **Purpose**

Gets the device number or channel number for a device.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/file.h>
int fp_getdevno ( fp, devp, chanp)
```

```
struct file *fp;
dev t *devp;
chan_t *chanp;
```

### **Parameters**

Points to a file structure returned by the fp\_open or fp\_opendev service.

devp Points to a location where the device number is to be returned. Points to a location where the channel number is to be returned. chanp

# **Description**

The fp\_getdevno service finds the device number and channel number for an open device that is associated with the file pointer specified by the fp parameter. If the value of either devp or chanp parameter is null, this service does not attempt to return any value for the argument.

## **Execution Environment**

The **fp getdevno** kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

EINVAL Indicates that the pointer specified by the fp parameter does not point to a file structure for an open

device.

## **Related Information**

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_getf Kernel Service

# **Purpose**

Retrieves a pointer to a file structure.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> int fp\_getf ( fd, fpp) int fd: struct file \*\*fpp;

#### **Parameters**

fd Specifies a file descriptor.

Points to the location where the file pointer is to be returned. fpp

# **Description**

A process calls the fp\_getf kernel service when it has a file descriptor for an open file, but needs a file pointer to use other Logical File System services.

The fp getf kernel service uses the file descriptor as an index into the process's open file table. From this table it extracts a pointer to the associated file structure.

As a side effect of the call to the fp\_getf kernel service, the reference count on the file descriptor is incremented. This count must be decremented when the caller has completed its use of the returned file pointer. The file descriptor reference count is decremented by a call to the ufdrele kernel service.

### **Execution Environment**

The **fp\_getf** kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful operation.

**EBADF** Indicates that either the file descriptor is invalid or not currently used in the process.

### **Related Information**

The ufdrele kernel service.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_hold Kernel Service

## **Purpose**

Increments the open count for a specified file pointer.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
void fp_hold (fp)
struct file *fp;
```

#### **Parameter**

Points to a file structure previously obtained by calling the fp\_open, fp\_getf, or fp\_opendev kernel service.

# **Description**

The **fp\_hold** kernel service increments the use count in the file structure specified by the *fp* parameter. This results in the associated file remaining opened even when the original open is closed.

If this function is used, and access to the file associated with the pointer specified by the fp parameter is no longer required, the fp\_close kernel service should be called to decrement the use count and close the file as required.

#### **Execution Environment**

The **fp\_hold** kernel service can be called from the process environment only.

## **Related Information**

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## fp\_ioctl Kernel Service

## **Purpose**

Issues a control command to an open device or file.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>

int fp_ioctl (fp, cmd, arg, ext)
struct file * fp;
unsigned int cmd;
caddr_t arg;
int ext;
```

## **Parameters**

fp Points to a file structure returned by the **fp\_open** or **fp\_opendev** kernel service.

cmd Specifies the specific control command requested.

arg Indicates the data required for the command.

ext Specifies an extension argument required by some device drivers. Its content, form, and use are determined by the individual driver.

# **Description**

The **fp\_ioctl** kernel service is an internal interface to the function provided by the **ioctl** subroutine.

### **Execution Environment**

The **fp ioctl** kernel service can be called from the process environment only.

### **Return Values**

0 Indicates a successful operation.

If an error occurs, one of the values from the /usr/include/sys/errno.h file is returned. The ioctl subroutine contains valid errno values.

#### **Related Information**

The ioctl subroutine.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_ioctl Kernel Service for Data Link Control (DLC) Devices

# **Purpose**

Transfers special commands from the kernel to generic data link control (GDLC) using a file pointer.

## **Syntax**

#include <sys/gdlextcb.h> #include <fcntl.h> int fp\_ioctl (fp, cmd, arg, ext)

#### **Parameters**

Specifies the file pointer of the target GDLC.

Specifies the operation to be performed by GDLC. For a cmd

listing of all possible operators, see "ioctl Operations (op) for DLC"AIX Version 7.1 Technical Reference:

Communications, Volume 1.

arg Specifies the address of the parameter block. The

> argument for this parameter must be in the kernel space. For a listing of possible values, see "Parameter Blocks by

ioctl Operation for DLC"AIX Version 7.1 Technical

Reference: Communications, Volume 1.

Specifies the extension parameter. This parameter is ext

ignored by GDLC.

# **Description**

Various GDLC functions can be initiated using the fp\_ioctl kernel service, such as changing configuration parameters, contacting the remote, and testing a link. Most of these operations can be completed before returning to the user synchronously. Some operations take longer, so asynchronous results are returned much later using the exception function handler. GDLC calls the kernel user's exception handler to complete these results. Each GDLC supports the fp\_ioctl kernel service by way of its dlcioctl entry point. The **fp ioctl** kernel service may be called from the process environment only.

Note: The DLC GET EXCEP ioctl operation is not used since all exception conditions are passed to the kernel user through the exception handler.

### **Return Values**

Indicates a successful completion. **ENXIO** Indicates an invalid file pointer. **EINVAL** Indicates an invalid value.

**ENOMEM** Indicates insufficient resources to satisfy the ioctl

subroutine.

These return values are defined in the /usr/include/sys/errno.h file.

#### Related Information

The fp\_ioctl kernel service.

The **ioctl** subroutine.

The **ioctl** subroutine interface for DLC devices.

Generic Data Link Control (GDLC) Environment Overview in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_ioctlx Kernel Service

## **Purpose**

Issues a control command to an open device.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <fcntl.h>

int fp_ioctlx (fp, cmd, arg, ext, flags, retval)
struct file *fp;
unsigned long cmd;
caddr_t arg;
ext_t ext;
unsigned long flags;
long *retval;
```

# **Description**

The fp\_ioctlx kernel service is an internal interface to the function provided by the ioctl subroutine.

The **fp\_ioctlx** kernel service issues a control command to an open device. Some drivers need the return value that is returned by the kernel service if there is no error. This value is not available through the **fp\_ioctl** kernel service. The **fp\_ioctlx** kernel service allows this data to be passed.

## **Parameters**

fp	Points to a	ile s	tructure	returned	by 1	the <b>f</b>	<b>p_open</b> or t	fp_opend	l <b>ev</b> kerne	l service.
----	-------------	-------	----------	----------	------	--------------	--------------------	----------	-------------------	------------

cmd Specifies the specific control command requested.arg Indicates the data required for the command.

ext Specifies an extension argument required by some device drivers. Its content, form, and use

are determined by the individual driver.

flags Indicates the address space of arg parameter. If the arg value is in kernel address space,

flags should be specified as FKERNEL. Otherwise, it should be zero (drivers pass data that

is in user space).

retval Points to the location where the return value will be stored on successful return from the call.

#### **Execution Environment**

The **fp\_ioctlx** kernel service can be called only from the process environment.

### **Return Values**

Upon successful completion, the **fp\_ioctlx** kernel service returns 0. If unsuccessful, one of the values from the **/usr/include/sys/errno.h** file is returned. The **ioctl** subroutine contains valid **errno** values. This value will be stored in the *retval* parameter.

#### Related Information

The ioctl, ioctlx, ioctl32, or ioctl32x Subroutine in AIX® Version 7.1 Technical Reference: Base Operating System and Extensions, Volume 1.

# fp\_lseek, fp\_llseek Kernel Service

## **Purpose**

Changes the current offset in an open file.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int fp_lseek ( fp, offset, whence)
struct file *fp;
off t offset;
int whence;
int fp_llseek
(fp, offset, whence)
struct file *fp
offset_t offset;
int whence;
```

### **Parameters**

Points to a file structure returned by the fp\_open kernel service.

offset Specifies the number of bytes (positive or negative) to move the file pointer.

whence Indicates how to use the offset value:

SEEK\_SET

Sets file pointer equal to the number of bytes specified by the *offset* parameter.

**SEEK CUR** 

Adds the number of bytes specified by the offset parameter to current file pointer.

**SEEK END** 

Adds the number of bytes specified by the offset parameter to current end of file.

# **Description**

The fp\_lseek and fp\_llseek kernel services are internal interfaces to the function provided by the lseek and IIseek subroutines.

#### **Execution Environment**

The fp\_lseek and fp\_llseek kernel services can be called from the process environment only.

### **Return Values**

Indicates a successful operation.

**ERRNO** Returns an error number from the /usr/include/sys/errno.h file on failure.

## **Related Information**

The Iseek, IIseek subroutine.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_open Kernel Service

# **Purpose**

Opens special and regular files or directories.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>

int fp_open (path, oflags, cmode, ext, segflag, fpp)
char * path;
unsigned oflags;
unsigned cmode;
int ext;
unsigned segflag;
struct file ** fpp;
```

### **Parameters**

path Points to the file name of the file to be opened.

oflags Specifies open mode flags as described in the **open** subroutine.

cmode Specifies the mode (permissions) value to be given to the file if the file is to be created.

ext Specifies an extension argument required by some device drivers. Individual drivers determine its

content, form, and use.

segflag Specifies the flag indicating where the pointer specified by the path parameter is located:

SYS ADSPACE

The pointer specified by the *path* parameter is stored in kernel memory.

**USER ADSPACE** 

The pointer specified by the *path* parameter is stored in application memory.

points to the location where the file structure pointer is to be returned by the **fp\_open** service.

# **Description**

The **fp\_open** kernel service provides a common service used by:

- The file system for the implementation of the open subroutine
- · Kernel routines outside the file system that must open files

#### **Execution Environment**

The **fp\_open** kernel service can be called from the process environment only.

#### **Return Values**

0 Indicates a successful operation.

Also, the *fpp* parameter points to an open file structure that is valid for use with the other Logical File System services. If an error occurs, one of the values from the /usr/include/sys/errno.h file is returned. The discussion of the **open** subroutine contains possible **errno** values.

## **Related Information**

The **open** subroutine.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_open Kernel Service for Data Link Control (DLC) Devices

## **Purpose**

Allows kernel to open the generic data link control (GDLC) device manager by its device name.

# **Syntax**

#include <sys/gdlextcb.h> #include <fcntl.h> fp\_open (path, oflags, cmode, ext, segflag, fpp)

## **Parameters**

path Consists of a character string containing the /dev special file name of the GDLC device manager, with the name of the communications device handler appended. The format is shown in the following example: /dev/dlcether/ent0 Specifies a value to set the file status flag. The GDLC oflags device manager ignores all but the following values: O RDWR Open for reading and writing. This must be set for GDLC or the open will not be successful. O\_NDELAY, O\_NONBLOCK Subsequent writes return immediately if no resources are available. The calling process is not put to sleep. Specifies the **O\_CREAT** mode parameter. This is ignored cmode by GDLC. ext Specifies the extended kernel service parameter. This is a pointer to the dlc\_open\_ext extended I/O structure for open subroutines. The argument for this parameter must be in the kernel space. "open Subroutine Extended Parameters for DLC"AIX Version 7.1 Technical Reference: Communications, Volume 1 provides more information on the extension parameter. Specifies the segment flag indicating where the path segflag parameter is located: FP\_SYS The path parameter is stored in kernel memory. FP\_USR

fpp

Specifies the returned file pointer. This parameter is passed by reference and updated by the file I/O subsystem to be the file pointer for this open subroutine.

memory.

The path parameter is stored in application

## **Description**

The fp\_open kernel service allows the kernel user to open a GDLC device manager by specifying the special file names of both the DLC and the communications device handler. Since the GDLC device manager is multiplexed, more than one process can open it (or the same process multiple times) and still have unique channel identifications.

Each open carries the communications device handler's special file name so that the DLC knows which port to transfer data on.

The kernel user must also provide functional entry addresses in order to obtain receive data and exception conditions. Each GDLC supports the **fp open** kernel service via its **dlcopen** entry point. The **fp open** kernel service may be called from the process environment only. "Using GDLC Special Kernel Services" in AIX® Version 6.1 Communications Programming Concepts provides additional information.

#### **Return Values**

Upon successful completion, this service returns a value of 0 and a valid file pointer in the fpp parameter.

**ECHILD** Indicates that the service cannot create a kernel process. **EINVAL** Indicates an invalid value. **ENODEV** Indicates that no such device handler is present. **ENOMEM** Indicates insufficient resources to satisfy the open. **EFAULT** Indicates that the kernel service, such as the copyin or initp service, has failed.

These return values are defined in the /usr/include/sys/errno.h file.

#### **Related Information**

The **copyin** kernel service, **fp open** kernel service, **initp** kernel service.

The **fp\_close** kernel service for data link control (DLC) devices.

open Subroutine Extended Parameters for DLC in AIX Version 7.1 Technical Reference: Communications, Volume 1.

Generic Data Link Control (GDLC) Environment Overview and Using GDLC Special Kernel Services in AIX Version 7.1 Communications Programming Concepts.

# fp opendev Kernel Service

# Purpose

Opens a device special file.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int fp opendev (devno, devflag, channame, ext, fpp)
dev_t devno;
int devflag;
char * channame;
int ext;
struct file** fpp;
```

## **Parameters**

devno Specifies the major and minor device number of device driver to open.

devflag Specifies one of the following values:

**DREAD** 

The device is being opened for reading only.

**DWRITE** 

The device is being opened for writing.

**DNDELAY** 

The device is being opened in nonblocking mode.

channame Points to a channel specifying a character string or a null value.

ext Specifies an extension argument required by some device drivers. Its content, form, and use are

determined by the individual driver.

fpp Specifies the returned file pointer. This parameter is passed by reference and is updated by the

fp opendev service to be the file pointer for this open instance. This file pointer is used as input to

other Logical File System services to specify the open instance.

## **Description**

The kernel or kernel extension calls the **fp\_opendev** kernel service to open a device by specifying its device major and minor number. The **fp\_opendev** kernel service provides the correct semantics for opening the character or multiplexed class of device drivers.

If the specified device driver is nonmultiplexed:

- · An in-core i-node is found or created for this device.
- · The i-node reference count is incremented.
- The device driver's **ddopen** entry point is called with the *devno*, *devflag*, and *ext* parameters. The unused *chan* parameter on the call to the **ddopen** routine is set to 0.

If the device driver is a multiplexed character device driver (that is, its **ddmpx** entry point is defined), an in-core i-node is created for this channel. The device driver's **ddmpx** routine is also called with the *channame* pointer to the channel identification string if non-null. If the *channame* pointer is null, the **ddmpx** device driver routine is called with the pointer to a null character string.

If the device driver can allocate the channel, the **ddmpx** routine returns a channel ID, represented by the *chan* parameter. If the device driver cannot allocate a channel, the **fp\_opendev** kernel service returns an **ENXIO** error code. If successful, the i-node reference count is incremented. The device driver's **ddopen** routine is also called with the *devno*, *devflag*, *chan* (provided by **ddmpx** routine), and *ext* parameters.

If the return value from the specified device driver's **ddopen** routine is nonzero, it is returned as the return code for the **fp\_opendev** kernel service. If the return code from the device driver's **ddopen** routine is 0, the **fp\_opendev** service returns the file pointer corresponding to this open of the device.

The **fp\_opendev** kernel service can only be called in the process environment or device driver top half. Interrupt handlers cannot call it. It is assumed that all arguments to the **fp\_opendev** kernel service are in kernel space.

The file pointer (*fpp*) returned by the **fp\_opendev** kernel service is only valid for use with a subset of the Logical File System services. These nine services can be called:

- · fp\_close
- fp\_ioctl
- fp\_poll
- fp\_select

- fp\_read
- fp readv
- fp\_rwuio
- fp\_write
- fp writev

Other services return an EINVAL return value if called.

### **Execution Environment**

The **fp\_opendev** kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful operation.

The \*fpp field also points to an open file structure that is valid for use with the other Logical File System services. If an error occurs, one of the following values from the /usr/include/sys/errno.h file is returned:

**EINVAL** Indicates that the major portion of the devno parameter exceeds the maximum number allowed, or the

devflags parameter is not valid.

**ENODEV** Indicates that the device does not exist.

Indicates that the signal was caught while processing the fp\_opendev request. EINTR

ENFILE Indicates that the system file table is full.

**ENXIO** Indicates that the device is multiplexed and unable to allocate the channel.

The **fp opendev** service also returns any nonzero return code returned from a device driver **ddopen** routine

### **Related Information**

The ddopen Device Driver Entry Point.

The fp\_close kernel service, fp\_ioctl kernel service, fp\_poll kernel service, fp\_read kernel service, fp readv kernel service, fp rwuio kernel service, fp select kernel service, fp write kernel service, **fp\_writev** kernel service.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_poll Kernel Service

# **Purpose**

Checks the I/O status of multiple file pointers, file descriptors, and message queues.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/poll.h>
int fp_poll (listptr, nfdsmsgs, timeout, flags)
void * listptr;
```

unsigned long nfdsmsgs; long timeout; uint flags;

### **Parameters**

listptr Points to an array of pollfd or pollmsg structures, or to a single pollist structure. Each structure

specifies a file pointer, file descriptor, or message queue ID. The events of interest for this file or

message queue are also specified.

nfdsmsgs Specifies the number of files and message queues to check. The low-order 16 bits give the number

of elements present in the array of pollfd structures. The high-order 16 bits give the number of elements present in the array of **pollmsg** structures. If either half of the *nfdsmsgs* parameter is equal

to 0, then the corresponding array is presumed abse1e.

timeout Specifies how long the service waits for a specified event to occur. If the value of this parameter is

> -1, the fp\_poll kernel service does not return until at least one of the specified events has occurred. If the time-out value is 0, the fp\_poll kernel service does not wait for an event to occur. Instead, the service returns immediately even if none of the specified events have occurred. For any other value of the timeout parameter, the fp\_poll kernel service specifies the maximum length of time (in

milliseconds) to wait for at least one of the specified events to occur.

flags Specifies the type of data in the *listptr* parameter:

**POLL FDMSG** 

Input is a file descriptor and/or message queue.

Input is a file pointer.

## **Description**

Note: The fp\_poll service applies only to character devices, pipes, message queues, and sockets. Not all character device drivers support the fp\_poll service.

The fp poll kernel service checks the specified file pointers/descriptors and message queues to see if they are ready for reading or writing, or if they have an exceptional condition pending.

The pollfd, pollmsg, and pollist structures are defined in the /usr/include/sys/poll.h file. These are the same structures described for the poll subroutine. One difference is that the fd field in the pollfd structure contains a file pointer when the flags parameter on the fp poll kernel service equals 0 (zero). If the flags parameter is set to a POLL FDMSG value, the field is taken as a file descriptor in all processed pollfd structures. If either the fd or msgid fields in their respective structures has a negative value, the processing for that structure is skipped.

When performing a poll operation on both files and message queues, the listptr parameter points to a pollist structure, which can specify both files and message queues. To construct a pollist structure, use the **POLLIST** macro as described in the **poll** subroutine.

If the number of **pollfd** elements in the *nfdsmsgs* parameter is 0, then the *listptr* parameter must point to an array of **pollmsg** structures.

If the number of **pollmsq** elements in the *nfdsmsqs* parameter is 0, then the *listptr* parameter must point to an array of **pollfd** structures.

If the number of **pollmsg** and **pollfd** elements are both nonzero in the *nfdsmsgs* parameter, the *listptr* parameter must point to a pollist structure as previously defined.

#### **Execution Environment**

The **fp\_poll** kernel service can be called from the process environment only.

### **Return Values**

Upon successful completion, the fp\_poll kernel service returns a value that indicates the total number of files and message queues that satisfy the selection criteria. The return value is similar to the nfdsmsgs parameter in the following ways:

- The low-order 16 bits give the number of files.
- The high-order 16 bits give the number of message queue identifiers that have nonzero revents values.

Use the NFDS and NMSGS macros to separate these two values from the return value. A return code of 0 (zero) indicates that:

- · The call has timed out.
- None of the specified files or message queues indicates the presence of an event.

In other words, all revents fields are 0 (zero).

When the return code from the fp poll kernel service is negative, it is set to the following value:

**EINTR** Indicates that a signal was caught during the fp\_poll kernel service.

#### **Related Information**

The **poll** subroutine.

The **selreg** kernel service.

# fp\_read Kernel Service

# **Purpose**

Performs a read on an open file with arguments passed.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int fp_read (fp, buf, nbytes, ext, segflag, countp)
struct file * fp;
char * buf;
int nbytes;
int
    ext;
int segflag;
int * countp;
```

#### **Parameters**

ext

Points to a file structure returned by the **fp\_open** or **fp\_opendev** kernel service.

buf Points to the buffer where data read from the file is to be stored. nbytes Specifies the number of bytes to be read from the file into the buffer.

Specifies an extension argument required by some device drivers. Its content, form, and use are

determined by the individual driver.

segflag Indicates in which part of memory the buffer specified by the buf parameter is located:

SYS\_ADSPACE

The buffer specified by the buf parameter is in kernel memory.

**USER ADSPACE** 

The buffer specified by the buf parameter is in application memory.

Points to the location where the count of bytes actually read from the file is to be returned. countp

# **Description**

The fp\_read kernel service is an internal interface to the function provided by the read subroutine.

### **Execution Environment**

The **fp\_read** kernel service can be called from the process environment only.

### **Return Values**

0 Indicates successful completion.

If an error occurs, one of the values from the /usr/include/sys/errno.h file is returned.

### **Related Information**

The read subroutine.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_readv Kernel Service

# **Purpose**

Performs a read operation on an open file with arguments passed in iovec elements.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int fp readv
(fp, iov, iovcnt, ext,
segflag, countp)
struct file * fp;
char * iov;
int iovcnt;
int
    ext;
int segflag;
int * countp;
```

#### **Parameters**

fp Points to a file structure returned by the **fp\_open** kernel service.

iov Points to an array of iovec elements. Each iovec element describes a buffer where data to be read from the file is to be stored.

iovent Specifies the number of iovec elements in the array pointed to by the iov parameter.

ext Specifies an extension argument required by some device drivers. Its content, form, and use are

determined by the individual driver.

segflag Indicates in which part of memory the array specified by the iov parameter is located:

SYS ADSPACE

The array specified by the *iov* parameter is in kernel memory.

**USER ADSPACE** 

The array specified by the *iov* parameter is in application memory.

countp Points to the location where the count of bytes actually read from the file is to be returned.

## **Description**

The **fp\_readv** kernel service is an internal interface to the function provided by the **readv** subroutine.

### **Execution Environment**

The **fp\_readv** kernel service can be called from the process environment only.

#### **Return Values**

0 Indicates a successful operation.

If an error occurs, one of the values from the /usr/include/sys/errno.h file is returned.

#### **Related Information**

The readv subroutine.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_rwuio Kernel Service

# **Purpose**

Performs read and write on an open file with arguments passed in a uio structure.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>

int fp_rwuio
( fp, rw, uiop, ext)
struct file *fp;
enum uio_rw rw;
struct uio *uiop;
int ext;
```

### **Parameters**

rw

*fp* Points to a file structure returned by the **fp\_open** or **fp\_opendev** kernel service.

Indicates whether this is a read operation or a write operation. It has a value of UIO\_READ or UIO\_WRITE.

uiop Points to a **uio** structure, which contains information such as where to move data and how much to move.

Specifies an extension argument required by some device drivers. Its content, form, and use are determined by the individual driver.

## **Description**

ext

The fp\_rwuio kernel service is not the preferred interface for read and write operations. The fp\_rwuio kernel service should only be used if the calling routine has been passed a uio structure. If the calling routine has not been passed a uio structure, it should not attempt to construct one and call the fp\_rwuio kernel service with it. Rather, it should pass the requisite uio components to the fp\_read or fp\_write kernel services.

#### **Execution Environment**

The **fp\_rwuio** kernel service can be called from the process environment only.

#### **Return Values**

0 Indicates a successful operation.

If an error occurs, one of the values from the /usr/include/sys/errno.h file is returned.

### **Related Information**

The **uio** structure.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp select Kernel Service

# **Purpose**

Provides for cascaded, or redirected, support of the select or poll request.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> int fp select ( fp, events, rtneventp, notify) struct file \*fp: ushort events; ushort \*rtneventp; void (\*notify)();

#### **Parameters**

fp Points to the open instance of the device driver, socket, or pipe for which the low-level select operation is intended.

events

Identifies the events that are to be checked. There are three standard event flags defined for the poll and select functions and one informational flag. The /usr/include/sys/poll.h file details the event bit definition. The four basic indicators are:

#### **POLLIN**

Input is present for the specified object.

#### **POLLOUT**

The specified file object is capable of accepting output.

#### **POLLPRI**

An exception condition has occurred on the specified object.

#### **POLLSYNC**

This is a synchronous request only. If none of the requested events are true, the selected routine should not remember this request as pending. That is, the routine does not need to call the **selnotify** service because of this request.

rtneventp

Indicates the returned events pointer. This parameter, passed by reference, is used to indicate which selected events are true at the current time. The returned event bits include the requested events plus an additional error event indicator:

#### **POLLERR**

An error condition was indicated by the object's select routine. If this flag is set, the nonzero return code from the specified object's select routine is returned as the return code from the **fp\_select** kernel service.

notify

Points to a routine to be called when the specified object invokes the selnotify kernel service for an outstanding asynchronous select or poll event request. If no routine is to be called, this parameter must be NULL.

## **Description**

The fp\_select kernel service is a low-level service used by kernel extensions to perform a select operation for an open device, socket, or named pipe. The fp\_select kernel service can be used for both synchronous and asynchronous select requests. Synchronous requests report on the current state of a device, and asynchronous requests allow the caller to be notified of future events on a device.

### Invocation from a Device Driver's ddselect Routine

A device driver's **ddselect** routine can call the **fp\_select** kernel service to pass select/poll requests to other device drivers. The ddselect routine for one device invokes the fp\_select kernel service, which calls the **ddselect** routine for a second device, and so on. This is required when event information for the original device depends upon events occurring on other devices. A cascaded chain of select requests can be initiated that involves more than two devices, or a single device can issue fp select calls to several other devices.

Each **ddselect** routine should preserve, in its call to the **fp select** kernel service, the same **POLLSYNC** indicator that it received when previously called by the fp select kernel service.

#### Invocation from Outside a Device Driver's ddselect Routine

If the fp select kernel service is invoked outside of the device driver's ddselect routine, the fp select kernel service sets the **POLLSYNC** flag, always making the request synchronous. In this case, no notification of future events for the specified device occurs, nor is a notify routine called, if specified. The fp\_select kernel service can be used in this manner (unrelated to a poll or select request in progress) to check an object's current status.

## Asynchronous Processing and the Use of the notify Routine

For asynchronous requests, the fp\_select kernel service allows its callers to register a notify routine to be called by the kernel when specified events become true. When the relevant device driver detects that one

or more pending events have become true, it invokes the selnotify kernel service. The selnotify kernel service then calls the notify routine, if one has been registered. Thus, the notify routine is called at interrupt time and must be programmed to run in an interrupt environment.

Use of a notify routine affects both the calling sequence at interrupt time and how the requested information is actually reported. Generalized asynchronous processing entails the following sequence of events:

- 1. A select request is initiated on a device and passed on (by multiple fp select kernel service invocations) to further devices. Eventually, a device driver's ddselect routine that is not dependent on other devices for information is reached. This **ddselect** routine finds that none of the requested events are true, but remembers the asynchronous request, and returns to the caller. In this way, the entire chain of calls is backed out, until the origin of the select request is reached. The kernel then puts the originating process to sleep.
- 2. Later, one or more events become true for the device remembering the asynchronous request. The device driver routine (possibly an interrupt handler) calls the selnotify kernel service.
- 3. If the events are still being waited on, the selnotify kernel service responds in one of two ways. If no notify routine was registered when the select request was made for the device, then all processes waiting for events on this device are awakened. If a notify routine exists for the device, then this routine is called. The **notify** routine determines whether the original requested event should be reported as true, and if so, calls the **selnotify** kernel service on its own.

The following example details a cascaded scenario involving several devices. Suppose that a request has been made for Device A, and Device A depends on Device B, which depends on Device C. When specified events become true at Device C, the selnotify kernel service called from Device C's device driver performs differently depending on whether a notify routine was registered at the time of the request.

### Cascaded Processing without the Use of notify Routines

If no notify routine was registered from Device B, then the selnotify kernel service determines that the specified events are to be considered true for the device driver at the head of the cascading chain. (The head of the chain, in this case Device A, is the first device driver to issue the fp\_select kernel service from its select routine.) The selnotify kernel service awakens all processes waiting for events that have occurred on Device A.

It is important to note that when no notify routine is used, any device driver in the calling chain that reports an event with the selnotify kernel service causes that event to appear true for the first device in the chain. As a result, any processes waiting for events that have occurred on that first device are awakened.

### **Cascaded Processing with notify Routines**

If, on the other hand, **notify** routines have been registered throughout the chain, then each interrupting device (by calling the selnotify kernel service) invokes the notify routine for the device above it in the calling chain. Thus in the preceding example, the selnotify kernel service for Device C calls the notify routine registered when Device B's ddselect routine invoked the fp select kernel service. Device B's notify routine must then decide whether to again call the selnotify kernel service to alert Device A's notify routine. If so, then Device A's notify routine is called, and makes its own determination whether to call another selnotify routine. If it does, the selnotify kernel service wakes up all the processes waiting on occurred events for Device A.

A variation on this scenario involves a cascaded chain in which only some device drivers have registered notify routines. In this case, the selnotify kernel service at each level calls the notify routine for the level above, until a level is encountered for which no notify routine was registered. At this point, all events of interest are determined to be true for the device driver at the head of the cascading chain. If any notify routines were registered in levels above the current level, they are never called.

### Returning from the fp\_select Kernel Service

The fp\_select kernel service does not wait for any selected events to become true, but returns immediately after the call to the object's **ddselect** routine has completed.

If the object's select routine is successfully called, the return code for the fp select kernel service is set to the return code provided by the object's **ddselect** routine.

#### **Execution Environment**

The fp select kernel service can be called from the process environment only.

#### **Return Values**

Indicates successful completion.

**EAGAIN** Indicates that the allocation of internal data structures failed. The rtneventp parameter is not updated. Indicates that the fp parameter is not a valid file pointer. The rtneventp parameter has the POLLNVAL **EINVAL** 

flag set.

The **fp\_select** kernel service can also be set to the nonzero return code from the specified object's ddselect routine. The rtneventp parameter has the POLLERR flag set.

#### Related Information

The **fp\_poll** kernel service, **selnotify** kernel service, **selreg** kernel service.

The fp\_select kernel service notify routine.

The **poll** subroutine, **select** subroutine.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_select Kernel Service notify Routine

# **Purpose**

Registers the **notify** routine.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> void notify (id, sub\_id, rtnevents, pid) int id; int sub id; ushort rtnevents; pid\_t pid;

#### **Parameters**

id

Indicates the selected function ID specified by the routine that made the call to the selnotify kernel service to indicate the occurrence of an outstanding event. For device drivers, this parameter is equivalent to the devno (device major and minor number) parameter.

sub\_id Indicates the unique ID specified by the routine that made the call to the selnotify kernel service to

indicate the occurrence of an outstanding event. For device drivers, this parameter is equivalent to

the chan parameter: channel for multiplexed drivers; 0 for nonmultiplexed drivers.

Specifies the rtnevents parameter supplied by the routine that made the call to the selnotify rtnevents

service indicating which events are designated as true.

Specifies the process ID of a process waiting for the event corresponding to this call of the **notify** pid

routine.

When a **notify** routine is provided for a cascaded function, the **selnotify** kernel service calls the specified notify routine instead of posting the process that was waiting on the event. It is up to this notify routine to determine if another selnotify call should be made to notify the waiting process of an event.

The **notify** routine is not called if the request is synchronous (that is, if the **POLLSYNC** flag is set in the events parameter) or if the original poll or select request is no longer outstanding.

Note: When more than one process has requested notification of an event and the fp\_select kernel service is used with a notify routine specified, the notification of the event causes the notify routine to be called once for each process that is currently waiting on one or more of the occurring events.

## **Description**

The fp\_select kernel service notify routine is registered by the caller of the fp\_select kernel service to be called by the kernel when specified events become true. The option to register this notify routine is available in a cascaded environment. The **notify** routine can be called at interrupt time.

### **Execution Environment**

The fp\_select kernel service notify routine can be called from either the process or interrupt environment.

#### Related Information

# fp write Kernel Service

# **Purpose**

Performs a write operation on an open file with arguments passed.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> int fp write (fp, buf, nbytes, ext, segflag, countp) struct file \* fp; char \* buf; int nbytes, int ext; int segflag; int \* countp;

### **Parameters**

fp Points to a file structure returned by the fp\_open or fp\_opendev kernel service.

buf Points to the buffer where data to be written to a file is located.

nbytes Indicates the number of bytes to be written to the file.

Specifies an extension argument required by some device drivers. Its content, form, and use are ext

determined by the individual driver.

segflag Indicates in which part of memory the buffer specified by the buf parameter is located:

SYS ADSPACE

The buffer specified by the buf parameter is in kernel memory.

**USER ADSPACE** 

The buffer specified by the *buf* parameter is in application memory.

Points to the location where count of bytes actually written to the file is to be returned. countp

## **Description**

The **fp write** kernel service is an internal interface to the function provided by the **write** subroutine.

#### **Execution Environment**

The fp\_write kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

ERRNO Returns an error number from the /usr/include/sys/errno.h file on failure.

### **Related Information**

The write subroutine.

Logical File System Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# fp\_write Kernel Service for Data Link Control (DLC) Devices

# **Purpose**

Allows kernel data to be sent using a file pointer.

# **Syntax**

#include <sys/gdlextcb.h> #include <sys/fp io.h>

int fp\_write (fp, buf, nbytes, ext, segflag, countp)

### **Parameters**

Specifies file pointer returned from the **fp\_open** kernel fp

service.

buf Points to a kernel mbuf structure. nbytes

ext

segflag

countp

Contains the byte length of the write data. It is not necessary to set this field to the actual length of write data, however, since the mbuf contains a length field. Instead, this field can be set to any non-negative value (generally set to 0).

Specifies the extended kernel service parameter. This is a pointer to the **dlc\_io\_ext** extended I/O structure for writes. The argument for this parameter must be in the kernel space. For more information on this parameter, see "write Subroutine Extended Parameters for DLC"AIX Version 7.1 Technical Reference: Communications, Volume 1. Specifies the segment flag indicating where the path parameter is located. The only valid value is:

#### FP SYS

The *path* parameter is stored in kernel memory. Points to the location where a count of bytes actually written is to be returned (must be in kernel space). GDLC does not provide this information for a kernel user since mbufs are used, but the file system requires a valid address and writes a copy of the *nbytes* parameter to that location.

# **Description**

Four types of data can be sent to generic data link control (GDLC). Network data can be sent to a service access point (SAP), and normal, exchange identification (XID) or datagram data can be sent to a link station (LS).

Kernel users pass a communications memory buffer (mbuf) directly to GDLC on the fp\_write kernel service. In this case, a uiomove kernel service is not required, and maximum performance can be achieved by merely passing the buffer pointer to GDLC. Each write buffer is required to have the proper buffer header information and enough space for the data link headers to be inserted. A write data offset is passed back to the kernel user at start LS completion for this purpose.

All data must fit into a single packet for each write call. That is, GDLC does not separate the user's write data area into multiple transmit packets. A maximum write data size is passed back to the user at DLC ENABLE SAP completion and at DLC START LS completion for this purpose.

Normally, a write subroutine can be satisfied immediately by GDLC by completing the data link headers and sending the transmit packet down to the device handler. In some cases, however, transmit packets can be blocked by the particular protocol's flow control or a resource outage. GDLC reacts to this differently, based on the system blocked/nonblocked file status flags (set by the file system and based on the O NDELAY and O NONBLOCKED values passed on the fp open kernel service). Nonblocked write subroutines that cannot get enough resources to queue the communications memory buffer (mbuf) return an error indication. Blocked write subroutines put the calling process to sleep until the resources free up or an error occurs. Each GDLC supports the fp write kernel service via its dlcwrite entry point. The fp\_write kernel service may be called from the process environment only.

#### **Return Values**

**EAGAIN** 

Indicates a successful operation. Indicates that transmit is temporarily blocked, and the calling process cannot be put to sleep.

**EINTR** Indicates that a signal interrupted the kernel service

before it could complete successfully.

**EINVAL** Indicates an invalid argument, such as too much data for

a single packet.

**ENXIO** Indicates an invalid file pointer.

These return values are defined in the /usr/include/sys/errno.h file.

# fp writev Kernel Service

## **Purpose**

Performs a write operation on an open file with arguments passed in iovec elements.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> int fp\_writev (fp, iov, iovcnt, ext, segflag, countp) struct file \* fp; struct iovec \* iov: int iovcnt; int ext; int segflag; int \* countp;

#### **Parameters**

Points to a file structure returned by the **fp\_open** kernel service. fр

Points to an array of iovec elements. Each iovec element describes a buffer containing data to be iov

written to the file.

iovcnt Specifies the number of **iovec** elements in an array pointed to by the *iov* parameter.

ext Specifies an extension argument required by some device drivers. Its content, form, and use are

determined by the individual driver.

segflag Indicates which part of memory the information designated by the iov parameter is located in:

SYS\_ADSPACE

The information designated by the *iov* parameter is in kernel memory.

**USER ADSPACE** 

The information designated by the *iov* parameter is in application memory.

Points to the location where the count of bytes actually written to the file is to be returned. countp

## **Description**

The fp\_writev kernel service is an internal interface to the function provided by the writev subroutine.

#### **Execution Environment**

The **fp\_writev** kernel service can be called from the process environment only.

### **Return Values**

**0** Indicates a successful operation.

If an error occurs, one of the values from the /usr/include/sys/errno.h file is returned.

### **Related Information**

The writev subroutine.

# fubyte Kernel Service

## **Purpose**

Retrieves a byte of data from user memory.

## **Syntax**

#include <sys/types.h> #include <sys/errno.h> int fubyte ( uaddr) uchar \*uaddr;

### **Parameter**

uaddr Specifies the address of the user data.

# **Description**

The **fubyte** kernel service fetches, or retrieves, a byte of data from the specified address in user memory. It is provided so that system calls and device heads can safely access user data. The **fubyte** service ensures that the user has the appropriate authority to:

- · Access the data.
- Protect the operating system from paging I/O errors on user data.

The fubyte service should be called only while executing in kernel mode in the user process.

#### **Execution Environment**

The **fubyte** kernel service can be called from the process environment only.

### **Return Values**

When successful, the **fubyte** service returns the specified byte.

-1 Indicates a *uaddr* parameter that is not valid.

The access is not valid under the following circumstances:

- The user does not have sufficient authority to access the data.
- · The address is not valid.
- An I/O error occurs while referencing the user data.

### **Related Information**

The **fuword** kernel service, **subyte** kernel service, **suword** kernel service.

Accessing User-Mode Data while in Kernel Mode and Memory Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### fuword Kernel Service

# **Purpose**

Retrieves a word of data from user memory.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int fuword ( uaddr)
int *uaddr:
```

#### **Parameter**

uaddr Specifies the address of user data.

# **Description**

The fuword kernel service retrieves a word of data from the specified address in user memory. It is provided so that system calls and device heads can safely access user data. The fuword service ensures that the user had the appropriate authority to:

- Access the data.
- Protect the operating system from paging I/O errors on user data.

The **fuword** service should be called only while executing in kernel mode in the user process.

#### **Execution Environment**

The fuword kernel service can be called from the process environment only.

#### **Return Values**

When successful, the fuword service returns the specified word of data.

Indicates a *uaddr* parameter that is not valid.

The access is not valid under the following circumstances:

The user does not have sufficient authority to access the data.

- The address is not valid.
- An I/O error occurred while referencing the user data.

For the fuword service, a retrieved value of -1 and a return code of -1 are indistinguishable.

#### **Related Information**

The **fubvte** kernel service, **subvte** kernel service, **suword** kernel service.

Accessing User-Mode Data while in Kernel Mode and Memory Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# getblk Kernel Service

## **Purpose**

Assigns a buffer to the specified block.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
struct buf *getblk
( dev, blkno)
dev t dev;
daddr t blkno;
```

### **Parameters**

dev Specifies the device containing the block to be allocated.

blkno Specifies the block to be allocated.

# **Description**

The getblk kernel service first checks whether the specified buffer is in the buffer cache. If the buffer resides there, but is in use, the e\_sleep service is called to wait until the buffer is no longer in use. Upon waking, the **getblk** service tries again to access the buffer. If the buffer is in the cache and not in use, it is removed from the free list and marked as busy. Its buffer header is then returned. If the buffer is not in the buffer cache, another buffer is taken from the free list and returned.

#### **Execution Environment**

The **getblk** kernel service can be called from the process environment only.

#### **Return Values**

The getblk service returns a pointer to the buffer header. A nonzero value for B\_ERROR in the b flags field of the buffer header (buf structure) indicates an error. If this occurs, the caller should release the block's buffer using the brelse kernel service.

On a platform that supports storage keys, the buffer header is allocated from the storage protected by the KKEY\_BLOCK\_DEV kernel key.

### **Related Information**

Block I/O Buffer Cache Kernel Services: Overview in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts summarizes how the bread, brelse, and getblk services uniquely manage the block I/O buffer cache.

I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## getc Kernel Service

### **Purpose**

Retrieves a character from a character list.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
int getc ( header)
struct clist *header;
```

#### **Parameter**

header Specifies the address of the clist structure that describes the character list.

## **Description**

Attention: The caller of the getc service must ensure that the character list is pinned. This includes the **clist** header and all the **cblock** character buffers. Otherwise, the system may crash.

The getc kernel service returns the character at the front of the character list. After returning the last character in the buffer, the getc service frees that buffer.

#### **Execution Environment**

The getc kernel service can be called from either the process or interrupt environment.

#### **Return Values**

Indicates that the character list is empty.

### **Related Information**

I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# getcb Kernel Service

# **Purpose**

Removes the first buffer from a character list and returns the address of the removed buffer.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
struct cblock *getcb
( header)
struct clist *header;
```

#### **Parameter**

header

Specifies the address of the clist structure that describes the character list.

## **Description**

Attention: The caller of the **getcb** service must ensure that the character list is pinned. This includes the clist header and all the cblock character buffers. Character buffers acquired from the getcf service are pinned. Otherwise, the system may crash.

The **getcb** kernel service returns the address of the character buffer at the start of the character list and removes that buffer from the character list. The user must free the buffer with the putcf service when finished with it.

#### **Execution Environment**

The **getcb** kernel service can be called from either the process or interrupt environment.

### **Return Values**

A null address indicates the character list is empty.

The getcb service returns the address of the character buffer at the start of the character list when the character list is not empty.

### **Related Information**

The getcf kernel service.

I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# getcbp Kernel Service

# **Purpose**

Retrieves multiple characters from a character buffer and places them at a designated address.

# **Syntax**

```
#include <cblock.h>
int getcbp ( header, dest, n)
struct clist *header;
char *dest;
int n:
```

#### **Parameters**

header Specifies the address of the clist structure that describes the character list.

dest Specifies the address where the characters obtained from the character list are to be placed.

Specifies the number of characters to be read from the character list.

### **Description**

Attention: The caller of the getcbp services must ensure that the character list is pinned. This includes the clist header and all the cblock character buffers. Character buffers acquired from the getcf service are pinned. Otherwise, the system may crash.

The **getcbp** kernel service retrieves as many as possible of the *n* characters requested from the character buffer at the start of the character list. The **getcbp** service then places them at the address pointed to by the *dest* parameter.

#### **Execution Environment**

The **getcbp** kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The **getcbp** service returns the number of characters retrieved from the character buffer.

### **Related Information**

The **getcf** kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# getcf Kernel Service

# Purpose

Retrieves a free character buffer.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <cblock.h struct cblock \*getcf ( )

# **Description**

The getcf kernel service retrieves a character buffer from the list of available ones and returns that buffer's address. The returned character buffer is pinned. If you use the getcf service to get a character buffer, be sure to free the space when you have finished using it. The buffers received from the getcf service should be freed by using the **putcf** kernel service.

Before starting the getcf service, the caller should request enough clist resources by using the pincf kernel service. The proper use of the getcf service ensures that there are sufficient pinned buffers available to the caller.

If the getcf service indicates that there is no available character buffer, the waitcfree service can be called to wait until a character buffer becomes available.

The **getcf** service has no parameters.

### **Execution Environment**

The **getcf** kernel service can be called from either the process or interrupt environment.

#### **Return Values**

Upon successful completion, the **getcf** service returns the address of the allocated character buffer.

A null pointer indicates no buffers are available.

#### **Related Information**

The **pincf** kernel service, **putcf** kernel service, **waitcfree** kernel service.

I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## getcx Kernel Service

## **Purpose**

Returns the character at the end of a designated list.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
int getcx ( header)
struct clist *header;
```

#### **Parameter**

header Specifies the address of the clist structure that describes the character list.

# **Description**

Attention: The caller of the **getcx** service must ensure that the character list is pinned. This includes the clist header and all the cblock character buffers. Character buffers acquired from the getcf service are pinned.

The getcx kernel service is identical to the getc service, except that the getcx service returns the character at the end of the list instead of the character at the front of the list. The character at the end of the list is the last character in the first buffer, not in the last buffer.

#### **Execution Environment**

The getcx kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The getcx service returns the character at the end of the list instead of the character at the front of the list.

### **Related Information**

The getcf kernel service.

I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## geteblk Kernel Service

# **Purpose**

Allocates a free buffer.

## Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
struct buf *geteblk ( )
```

# **Description**

Attention: The use of the geteblk service by character device drivers is strongly discouraged. As an alternative, character device drivers can use the xmalloc service to allocate the memory space directly, or the character I/O kernel services such as the **getcb** or **getcf** services.

The geteblk kernel service allocates a buffer and buffer header and returns the address of the buffer header. If no free buffers are available, then the geteblk service waits for one to become available. Block device drivers can retrieve buffers using the geteblk service.

In the header, the b forw, b back, b flags, b bcount, b dev, and b un fields are used by the system and cannot be modified by the driver. The av forw and av back fields are available to the user of the geteblk service for keeping a chain of buffers by the user of the geteblk service. (This user could be the kernel file system or a device driver.) The b\_blkno and b\_resid fields can be used for any purpose.

The **brelse** service is used to free this type of buffer.

The **geteblk** service has no parameters.

### **Execution Environment**

The geteblk kernel service can be called from the process environment only.

#### **Return Values**

The geteblk service returns a pointer to the buffer header. There are no error codes because the geteblk service waits until a buffer header becomes available.

On a platform that supports storage keys, the buffer header is allocated from the storage protected by the KKEY\_BLOCK\_DEV kernel key.

### **Related Information**

The **brelse** kernel service, **xmalloc** kernel service.

Block I/O Buffer Cache Kernel Services: Overview, I/O Kernel Services, buf Structure, Device Driver Concepts Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# geterror Kernel Service

# **Purpose**

Determines the completion status of the buffer.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
int geterror ( bp)
struct buf *bp;
```

#### **Parameter**

bp Specifies the address of the buffer structure whose status is to be checked.

On a platform that supports storage keys, the passed in bp parameter must be in the KKEY\_PUBLIC or KKEY\_BLOCK\_DEV protection domain.

# **Description**

The geterror kernel service checks the specified buffer to see if the b\_error flag is set. If that flag is not set, the geterror service returns 0. Otherwise, it returns the nonzero B ERROR value or the EIO value (if b error is 0).

#### **Execution Environment**

The geterror kernel service can be called from either the process or interrupt environment.

### **Return Values**

Indicates that no I/O error occurred on the buffer. b\_error value Indicates that an I/O error occurred on the buffer.

EIO Indicates that an unknown I/O error occurred on the buffer.

### **Related Information**

Block I/O Buffer Cache Kernel Services: Overview and I/O Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# getexcept Kernel Service

# **Purpose**

Allows kernel exception handlers to retrieve additional exception information.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/except.h>
void getexcept
( exceptp)
struct except *exceptp;
```

### **Parameter**

exceptp

Specifies the address of an except structure, as defined in the /usr/include/sys/except.h file. The getexcept service copies detailed exception data from the current machine-state save area into this caller-supplied structure.

## **Description**

The getexcept kernel service provides exception handlers the capability to retrieve additional information concerning the exception from the machine-state save area.

The **getexcept** service should only be used by exception handlers when called to handle an exception. The contents of the structure pointed at by the except parameter is platform-specific, but is described in the /usr/include/sys/except.h file for each type of exception that provides additional data. This data is typically included in any error logging data for the exception. It can be also used to attempt to handle or recover from the exception.

### **Execution Environment**

The **getexcept** kernel service can be called from either the process or interrupt environment. It should be called only when handling an exception.

### **Return Values**

The **getexcept** service has no return values.

#### Related Information

Kernel Extension and Device Driver Management Kernel Services and in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# getfslimit Kernel Service

# Purpose

Returns the maximum file size limit of the current process.

# **Syntax**

#include <sys/types.h> offset t getfslimit (void)

# **Description**

The getfslimit kernel service returns the file size limit of the current process as a 64 bit integer. This can be used by file systems to implement the checks needed to enforce limits. The **getfslimit** kernel service is called from the process environment.

### **Return Values**

The **getfslimit** kernel service returns the file size limit, there are no error values.

#### **Related Information**

The **ulimit** subroutine, **getrlimit** subroutine, **setrlimit** subroutine.

The ulimit command.

# get\_pag or get\_pag64 Kernel Service

## **Purpose**

Retrieves a Process Authentication Group (PAG) value for the current process.

## **Syntax**

```
#include <sys/cred.h>
int get_pag ( type, pag )
int type;
int *pag;
int get pag64 ( type, pag )
int type;
uint64_t *pag;
```

#### **Parameters**

PAG type to retrieve type

Pointer to buffer where operating system returns the PAG pag

## **Description**

The get pag and get pag64 kernel services copy the requested PAG from the current process into pag. The value of type must be a defined PAG ID. The PAG ID for the Distributed Computing Environment (DCE) is 0.

### **Execution Environment**

The **get pag** and **get pag64** kernel services can be called from the process environment only.

#### **Return Values**

A value of 0 is returned upon successful completion. If unsuccessful, errno is set to a value that explains the error.

#### **Error Codes**

The **get\_pag** kernel service fails if one or both of the following conditions are true:

**EINVAL** Invalid PAG specification

**EOVERFLOW** PAG value is 64-bit (should be using **get\_pag64**)

The **get\_pag64** kernel service fails if the following condition is true:

**EINVAL** Invalid PAG specification

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# getpid Kernel Service

## **Purpose**

Gets the process ID of the current process.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
pid_t getpid ()
```

# **Description**

The **getpid** kernel service returns the process ID of the calling process.

The **getpid** service can also be used to check the environment that the routine is being executed in. If the caller is executing in the interrupt environment, the getpid service returns a process ID of -1. If a routine is executing in a process environment, the getpid service obtains the current process ID.

### **Execution Environment**

The getpid kernel service can be called from either the process or interrupt environment.

### **Return Values**

-1 Indicates that the **getpid** service was called from an interrupt environment.

The **getpid** service returns the process ID of the current process if called from a process environment.

### **Related Information**

Process and Exception Management Kernel Services and Understanding Execution Environments in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# getppidx Kernel Service

# **Purpose**

Gets the parent process ID of the specified process.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
pid_t getppidx ( ProcessID)
pid t ProcessID;
```

#### **Parameter**

ProcessID

Specifies the process ID. If this parameter is 0, then the parent process ID of the calling process will be returned.

# **Description**

The **getppidx** kernel service returns the parent process ID of the specified process.

### **Execution Environment**

The **getppidx** kernel service can be called from the process environment only.

#### **Return Values**

-1 Indicates that the *ProcessID* parameter is invalid.

The **getppidx** service returns the parent process ID of the calling process.

#### **Related Information**

The getpid kernel service.

Process and Exception Management Kernel Services and Understanding Execution Environments in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# getuerror Kernel Service

## **Purpose**

Allows kernel extensions to read the ut error field for the current thread.

## **Syntax**

#include <sys/types.h> #include <sys/errno.h> int getuerror ()

# **Description**

The getuerror kernel service allows a kernel extension in a process environment to retrieve the current value of the current thread's ut error field. Kernel extensions can use the getuerror service when using system calls or other kernel services that return error information in the ut error field.

For system calls, the system call handler copies the value of the ut error field in the per thread uthread structure to the errno global variable before returning to the caller. However, when kernel services use available system calls, the system call handler is bypassed. The **getuerror** service must then be used to obtain error information.

#### **Execution Environment**

The **getuerror** kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful operation.

When an error occurs, the getuerror kernel service returns the current value of the ut\_error field in the per thread uthread structure. Possible return values for this field are defined in the /usr/include/sys/ errno.h file.

#### **Related Information**

The setuerror kernel service.

Kernel Extension and Device Driver Management Kernel Services and Understanding System Call Execution in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# getufdflags and setufdflags Kernel Services

## **Purpose**

Queries and sets file-descriptor flags.

# **Syntax**

#include <sys/user.h> int getufdflags(fd, flagsp) int fd; int \*flagsp; #include <sys/user.h> int setufdflags(fd, flags) int fd; int flags;

#### **Parameters**

fd Identifies the file descriptor.

flags Sets attribute flags for the specified file descriptor. Refer to the sys/user.h file for the list of valid flags. flagsp Points to an integer field where the flags associated with the file descriptor are stored on successful

return.

# **Description**

The setufdflags and getufdflags kernel services set and query the file descriptor flags. The file descriptor flags are listed in fontl.h.

### **Execution Environment**

These kernel services can be called from the process environment only.

### **Return Values**

Indicates successful completion.

**EBADF** Indicates that the fd parameter is not a file descriptor for an open file.

#### **Related Information**

The ufdhold and ufdrele kernel services.

# get\_umask Kernel Service

# **Purpose**

Queries the file mode creation mask.

# **Syntax**

int get umask(void)

# **Description**

The **get\_umask** service gets the value of the file mode creation mask currently set for the process.

Note: There is no corresponding kernel service to set the umask because kernel routines that need to set the umask can call the umask subroutine.

### **Execution Environment**

The **get\_umask** kernel service can be called from the process environment only.

#### **Return Values**

The get\_umask kernel service always completes successfully. Its return value is the current value of the umask.

### **Related Information**

The umask subroutine.

# gfsadd Kernel Service

## **Purpose**

Adds a file system type to the gfs table.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> int gfsadd ( gfsno, gfsp) int gfsno; struct gfs \*gfsp;

#### **Parameters**

Specifies the file system number. This small integer value is either defined in the /usr/include/sys/ afsno vmount.h file or a user-defined number of the same order.

gfsp Points to the file system description structure.

# **Description**

The gfsadd kernel service is used during configuration of a file system. The configuration routine for a file system invokes the gfsadd kernel service with a gfs structure. This structure describes the file system type.

The qfs structure type is defined in the /usr/include/sys/qfs.h file. The qfs structure must have the following fields filled in:

Field	Description
gfs_type	Specifies the integer type value. The predefined types are listed in the /usr/include/sys/vmount.h
	file.
gfs_name	Specifies the character string name of the file system. The maximum length of this field is 16 bytes.
	Shorter names must be null-padded.

#### Field

#### Description

gfs flags

Specifies the flags that define the capabilities of the file system. The following flag values are defined:

#### GFS\_AHAFS\_INFO

GFS supports AHAFS FS monitoring.

#### **GFS AIX FLOCK**

Uses common\_reclock() to manage advisory locks.

#### **GFS DIROP**

Call parent vnop instead of obj.

#### **GFS FASTPATH**

GFS supports AIO fast path.

#### GFS\_FUMNT

File system supports forced unmount.

#### **GFS INIT**

GFS has been initialized

#### **GFS MEMCNTL**

New memcntl vnode operation

#### **GFS MLS**

GFS supports MLS.

#### GFS\_NAMED\_OPEN

File system supports named open.

#### GFS\_NO\_ACCT

Do not do file system account on this file system.

#### GFS\_NOEXPORT

GFS cannot be exported by NFS.

#### GFS\_NOUMASK

File system does not apply umask when creating new objects.

#### GFS\_OFLAGS64

GFS supports 64 bit open flags.

#### **GFS REMNT**

File system supports remount of a mounted file system.

#### **GFS REMOTE**

File system is remote (ie. NFS).

#### **GFS STATFSVP**

File system supports vfs\_statfsvp VFS interface. (new vfs operation: vfs\_statfsvp)

#### GFS\_SYS5DIR

File system that uses the System V-type directory structure.

#### **GFS SYNCVFS**

The **syncvfs** vnode operation.

#### **GFS VERSION4**

File system supports AIX® Version 4 V-node interface.

#### GFS\_VERSION42

File system supports AIX® 4.2 V-node interface. (new vnode operation: vnop\_seek)

#### GFS\_VERSION421

File system supports AIX® 4.2.1 V-node interface.(new vnode operations:

vnop\_sync\_range, vnop\_create\_attr, vnop\_finfo, vnop\_map\_lloff, vnop\_readdir\_eofp, vnop\_rdwr\_attr)

#### GFS\_VERSION43

File system supports AIX<sup>®</sup> 4.3 V-node interface. (new file flag for vnop\_sync\_range:FMSYNC)

#### **GFS\_VERSION53**

Chapter 1. Kernel Services

189

Field Description

gfs\_ops Specifies the array of pointers to **vfs** operation implementations. gn\_ops Specifies the array of pointers to v-node operation implementations.

The file system description structure can also specify:

gfs init Points to an initialization routine to be called by the gfsadd kernel service. This field must be null if

no initialization routine is to be called.

gfs data Points to file system private data.

#### **Execution Environment**

The gfsadd kernel service can be called from the process environment only.

### **Return Values**

0 Indicates successful completion.

**EBUSY** Indicates that the file system type has already been installed.

**EINVAL** Indicates that the *gfsno* value is larger than the system-defined maximum. The system-defined maximum

is indicated in the /usr/include/sys/vmount.h file.

### **Related Information**

The gfsdel kernel service.

## gfsdel Kernel Service

# **Purpose**

Removes a file system type from the gfs table.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int gfsdel ( gfsno)
int gfsno;
```

#### **Parameter**

gfsno Specifies the file system number. This value identifies the type of the file system to be deleted.

# **Description**

The **gfsdel** kernel service is called to delete a file system type. It is not valid to mount any file system of the given type after that type has been deleted.

#### **Execution Environment**

The **gfsdel** kernel service can be called from the process environment only.

#### **Return Values**

0 Indicates successful completion.

**ENOENT** Indicates that the indicated file system type was not installed.

**EINVAL** Indicates that the gfsno value is larger than the system-defined maximum. The system-defined maximum

is indicated in the /usr/include/sys/vmount.h file.

**EBUSY** Indicates that there are active **vfs** structures for the file system type being deleted.

#### **Related Information**

Virtual File System Overview, Virtual File System Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

The **qfsadd** kernel service.

## gn\_closecnt Subroutine

## **Purpose**

Maintains the using count on a gnode structure.

# **Syntax**

```
#include <sys/vnode.h>
#include <sys/fcntl.h>
void gn_closecnt (gnode, flags)
struct gnode *gnode;
```

#### **Parameters**

long flags;

gnode Points to a **gnode** structure.

Specifies the open mode (FREAD, FWRITE, FEXEC, FRSHARE) from the open file flags. flags

# **Description**

The gn\_closecnt subroutine uses the passed in flags value to determine the appropriate using counts to decrease in the *gnode* structure. For example, if the **FREAD** flag is set, the **gn closecnt** subroutine decreases the gn\_rdcnt field. The following table shows the mapping of the flags value to the counts field in the *gnode* structure:

**FREAD** gn\_rdcnt **FWRITE** gn\_wrcnt **FEXEC** gn\_excnt FRSHARE gn\_rshcnt

#### **Return Values**

The **gn** closecnt subroutine returns no return values.

#### Error Codes

The **gn closecnt** subroutine returns no error codes.

#### **Related Information**

Understanding Data Structures and Header Files for Virtual File Systems in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## gn\_common\_memcntl Subroutine

## **Purpose**

Changes or queries the physical attachment of a file.

## **Syntax**

```
#include <sys/vnode.h>
#include <sys/fcntl.h>
int gn common memcntl (gnode, cmd, arg)
struct gnode * gnode;
int cmd;
void * arg;
```

#### **Parameters**

gnode Points to a gnode structure.

cmd Specifies the operation to be performed. The cmd parameter can be one of the following values:

> F\_ATTACH F\_DETACH F ATTINFO

Points to a structure containing information for the specified *cmd* parameter. arg

> F ATTACH attach\_desc\_t F\_DETACH detach\_desc\_t **F\_ATTINFO** attinfo\_desc\_t

# **Description**

The gn\_common\_memcntl subroutine is to be called by file system vnop\_memcntl implementations. It performs the normal function of such operations. If the cmd parameter is set to F\_ATTACH, the gn\_common\_memcntl subroutine attaches the segment specified by the gn\_seg field in the gnode structure. If the cmd parameter is set to F\_DETACH, the gn\_common\_memcntl subroutine detaches the segment. If the cmd parameter is set to F\_ATTINFO, the gn\_common\_memcntl subroutine returns information about the current state of attachment.

#### **Return Values**

Success. non-zero Failure.

## **Error Codes**

**EINVAL** The cmd parameter is not valid.

**ENOMEM** Resources are not available to attach the memory segment.

# gn\_mapcnt Subroutine

# **Purpose**

Maintains the mapping count in a **gnode** structure.

## **Syntax**

```
#include <sys/vnode.h>
#include <sys/shm.h>
void gn_mapcnt (gnode, flags)
struct gnode * gnode;
long flags;
```

### **Parameters**

gnode Points to a gnode structure.

flags Specifies the following mapping flag:

SHM RDONLY

Only read access is required.

## **Description**

The gn\_mapcnt subroutine uses the passed in flags value to determine the appropriate mapping count to increase in the gnode structure. If the SHM\_RDONLY flag is set, the gn\_mapcnt subroutine increases the gn\_mrdcnt field. Otherwise, the gn\_mapcnt subroutine increases the gn\_mwrcnt field.

#### Return Values

The **gn\_mapcnt** subroutine returns no return values.

#### **Error Codes**

The **gn mapcnt** subroutine returns no error codes.

#### **Related Information**

The mmap subroutine in AIX Version 7.1 Technical Reference: Base Operating System and Extensions, Volume 1.

The shmat subroutine in AIX Version 7.1 Technical Reference: Base Operating System and Extensions, Volume 2.

# gn\_opencnt Subroutine

# **Purpose**

Maintains the using count on a **gnode** structure.

# **Syntax**

```
#include <sys/vnode.h>
#include <sys/fcntl.h>
void gn opencnt (gnode, flags)
struct gnode * gnode;
long flags;
```

### **Parameters**

gnode Points to a **gnode** structure.

Specifies the open mode (FREAD, FWRITE, FEXEC, FRSHARE) from the open file flags. flags

# **Description**

The gn\_opencnt subroutine uses the passed in flags value to determine the appropriate using counts to increase in the gnode structure. The following table shows the mapping of the flags value to the counts field in the *gnode* structure:

**FREAD** gn\_rdcnt **FWRITE** gn\_wrcnt **FEXEC** an excnt **FRSHARE** gn\_rshcnt

#### **Return Values**

The **gn\_opencnt** subroutine returns no return values.

#### **Error Codes**

The **qn** opencnt subroutine returns no error codes.

#### **Related Information**

Understanding Data Structures and Header Files for Virtual File Systems in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## gn\_unmapcnt Subroutine

## **Purpose**

Maintains the mapping count in a gnode structure.

# **Syntax**

```
#include <sys/vnode.h>
#include <sys/shm.h>
void gn_unmapcnt (gnode, flags)
struct gnode * gnode;
long flags;
```

### **Parameters**

gnode Points to a gnode structure.

Specifies the following mapping flag: flags

SHM\_RDONLY

Only read access is required.

# **Description**

The gn\_unmapcnt subroutine uses the passed in flags value to determine the appropriate mapping count to decrease in the gnode structure. If the SHM\_RDONLY flag is set, the gn\_unmapcnt subroutine decreases the gn\_mrdcnt field. Otherwise, the gn\_unmapcnt subroutine decreases the gn\_mwrcnt field.

#### **Return Values**

The **gn\_unmapcnt** subroutine returns no return values.

### **Error Codes**

The **gn\_unmapcnt** subroutine returns no error codes.

#### **Related Information**

The mmap subroutine in AIX Version 7.1 Technical Reference: Base Operating System and Extensions, Volume 1.

The shmat subroutine in AIX Version 7.1 Technical Reference: Base Operating System and Extensions, Volume 2.

# groupmember, groupmember\_cr Subroutines

## **Purpose**

Determines if the named group is a member of a credential group set.

## **Syntax**

```
#include <sys/types.h>
#include <sys/cred.h>
int groupmember (gid)
gid_t gid;
int groupmember_cr (gid, cred)
gid_t gid;
cred t * cred;
```

#### **Parameters**

Specifies an identifier for a group. gid Points to a ucred structure. cred

# **Description**

The **groupmember** subroutines determine if a group is included in the group set of a credential structure. The groupmember subroutine queries the credential associated with the current thread. The groupmember\_cr subroutine checks for the group within the specified ucred structure.

#### **Return Values**

The groupmember subroutines return TRUE if the ucred structure contains the specified gid parameter or if the specified *gid* parameter is the current effective group ID for the thread. Otherwise, these routines return FALSE.

#### **Error Codes**

The **groupmember** subroutines return no error codes.

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## heap\_create Kernel Service

## **Purpose**

Initializes a new heap to be used with kernel memory management services. The **heap\_create** kernel service replaces the **init\_heap** kernel service. It returns a heap handle that can be used with the **xmalloc** and the **xmfree** kernel services.

## **Syntax**

```
#include <sys/types.h>
#include <sys/malloc.h>
#include <sys/skeys.h>
#include <sys/kerrno.h>
```

kerrno\_t heap\_create (heapattr\_t \* heapattr, heapaddr\_t \* heapptr);

### **Parameters**

heapattr Points to an initialized heap attribute structure. See the sys/malloc.h file. This

structure is initialized by the caller of heap\_create.

heapptr Points to an external heap descriptor. The caller must initialize this parameter to the

**HPA\_INVALID\_HEAP** value.

The *heapattr* structure contains the following fields:

eye\_catch8b\_t hpa\_eyec
short hpa\_version
long hpa\_flags

Must be initialized to the **EYEC\_HEAPATTR** value. Must be initialized to the **HPA\_VERSION** value. The following flags describe heap properties:

**HPA\_PAGED** 

The heap returns pageable memory.

**HPA\_PINNED** 

The heap returns pinned memory.

**HPA\_SHARED** 

The returned descriptor is backed by a common sub-heap.

**HPA\_PRIVATE** 

The returned descriptor is backed by isolated storage.

void \* hpa\_heapaddr

Must be set to NULL (reserved).

size\_t hpa\_heapsize

Heap size in bytes. It is only used for private heaps.

size\_t hpa\_limit

Usage barrier independent from size. Limits the amount available from a private heap

that is less than or equal to the actual size of the private heap.

long hpa\_debug\_level

Heap debug level. The HPA\_DEFAULT\_DEBUG value gives the heap the system

debug level.

uint hpa\_kkey

Kernel key requested for the storage allocated.

# **Description**

The **heap\_create** service is a replacement for the **init\_heap** service. It can be used to create private heaps, and to create shared sub-heaps. After this service creates a private heap or a handle to a shared sub-heap, the returned **heapaddr\_t** value can be used with the **xmalloc** service or the **xmfree** service to allocate or free memory from that heap.

The most common usage for the **heap\_create** service is to get a handle to a shared sub-heap. This is done by setting the **HPA\_SHARED** flag in the input attribute structure. See the **sys\_malloc.h** file.

Private heaps can be created by specifying the HPA\_PRIVATE flag. This allows the heap\_create service to initialize and manage an area of virtual memory as a private heap. The hpa heapaddr field must be set to zero. The heap\_create service provides the storage but this field is reserved for future use. The hpa\_size field indicates the size of the private heap in bytes.

Private heaps can make use of the hpa limit field. Use the hpa size field to reserve a maximum effective address space. Then use the hpa\_limit field to alter and control the amount of effective address space that is in use. The value of the hpa\_limit field must be less than or equal to the value of the hpa\_size field.

The hpa\_debug and hpa\_kkey fields are required for shared and private heaps. The hpa\_debug level allows a component run-time debug level to be applied to allocations using the returned heap handle. The hpa\_kkey field associates a kernel key with a sub-heap that can limit the kernel accessibility.

On a successful completion, the heapattr field contains the address of a heap structure. This can be used as a parameter to the xmalloc and the xmfree kernel services. The memory returned by these services and the internal heap structures are protected by the hpa kkey field. When calling the xmalloc and the xmfree heap services, the caller must hold the key that was used when creating the heap.

#### **Execution Environment**

The **heap create** kernel service can be called from the process environment only.

#### **Return Values**

EINVAL\_HEAP\_CREATE

Indicates a successful completion. A descriptor is returned in the heapptr

Indicates one or more of the following inputs that were not valid:

- · heapattr is NULL.
- \*heapptr != HPA\_INVALID\_HEAP.
- heapattr->hpa\_eyec != EYEC\_HEAPATTR.
- heapattr->hpa\_version != HPA\_VERSION.
- Flags: Both the HPA\_SHARED and the HPA\_PRIVATE flags are specified.
- Flags: Neither the HPA\_SHARED nor the HPA\_PRIVATE flag is specified.
- Flags: Both the HPA\_PINNED and the HPA\_PAGED flags are specified.
- Flags: Neither the HPA\_PINNED nor the HPA\_PAGED flag is specified.
- · Keys: kernel key specified is not valid.
- Other: Size is specified with a shared heap.
- · Other: Limit is specified with a shared heap.
- · Other: Address specified is not NULL.
- Other: Limit > size for private heap.
- Other: Private heap size is too small (less than 8M).

ENOMEM\_HEAP\_CREATE

Indicates insufficient memory available to complete the request.

#### **Related Information**

The heap modify kernel service, heap destroy kernel service

# heap\_destroy Kernel Service

## **Purpose**

Removes a heap.

## **Syntax**

```
#include <sys/types.h>
#include <sys/malloc.h>
#include <sys/kerrno.h>
kerrno t heap destroy (heapattr t heap, long flags);
```

#### **Parameters**

heap The heap to destroy. Must be zero. flags

# **Description**

This service removes a heap and its internal resources from the system. There must be no outstanding allocations when a heap is destroyed.

### **Execution Environment**

The **heap destroy** kernel service can be called from the process environment only.

### **Return Values**

EINVAL\_HEAP\_DESTROY The *heap* parameter is not recognizable.

EBUSY\_HEAP\_DESTROY The heap is still in use.

#### **Related Information**

The **heap\_create** kernel service.

The **heap\_modify** kernel service.

# heap\_modify Kernel Service

# **Purpose**

Modifies the attributes of a heap.

# **Syntax**

```
#include <sys/types.h>
#include <sys/malloc.h>
#include <sys/kerrno.h>
```

kerrno\_t heap modify (heapattr\_t heap, long command, long argument);

#### **Parameters**

heap The heap handle returned from the heap\_create kernel service. command Specifies the operation to perform. The following values are supported:

**HPA\_SET\_LIMIT** 

Modifies the limit value of a private heap.

**HPA SET DEBUG** 

Modifies the debug level. Debug levels from 0 to 9 are supported.

Command specific data (new limit or debug level). argument

## **Description**

The **heap\_modify** kernel service is used to alter the heap characteristics at run time.

### **Execution Environment**

The heap\_modify kernel service can be called from the process environment only with interrupts enabled.

### **Return Values**

Success.

EINVAL\_HEAP\_MODIFY The command or the execution environment is not valid.

ERANGE\_HEAP\_MODIFY Heap property is outside the supported range.

### **Related Information**

The heap\_create kernel service, heap\_destroy kernel service.

# hkeyset add, hkeyset replace, hkeyset restore, or hkeyset get Kernel Service

# **Purpose**

Manipulates the protection domain (page access as controlled by storage keys) in use for code execution in the kernel environment.

# **Syntax**

```
#include <sys/skeys.h>
```

```
hkeyset_t hkeyset_add ( hkeyset_t keyset );
hkeyset t hkeyset replace ( hkeyset t keyset );
void hkeyset_restore ( hkeyset_t keyset );
hkeyset t hkeyset get ( void );
```

### **Parameters**

keyset The hardware keyset to be activated.

# **Description**

If storage protection keys are enabled, every memory page has a hardware storage protection key associated with it. A keyset is a representation of the access rights to a set of storage protection keys. To access a memory page, a hardware keyset containing the storage key associated with the memory page must be active.

The hkeyset add kernel service updates the protection domain by adding the hardware keyset specified by the keyset parameter to the currently addressable hardware keyset. The previous hardware keyset is returned.

The hkeyset\_replace kernel service updates the protection domain by loading the hardware keyset specified by the keyset parameter as the currently addressable storage set. The previous hardware keyset is returned.

The hkeyset\_restore kernel service restores a caller's hardware keyset when returning from a module entry point. It does not return any value.

The hkeyset\_get kernel service reads the current hardware keyset without altering it.

### **Execution Environment**

The hkeyset\_add, hkeyset\_replace, hkeyset\_restore, or hkeyset\_get kernel service can be called from either the process environment or the interrupt environment.

#### **Return Values**

The hkeyset\_add, hkeyset\_replace, and hkeyset\_get kernel services return the keyset value that was active before the call. The hkeyset restore kernel service does not return any value.

### **Related Information**

Kernel Storage Protection Keys Concepts in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## hkeyset\_restore\_userkeys Kernel Service

## **Purpose**

Restores the previous user-memory access.

# **Syntax**

#include <sys/skeys.h>

kerrno t hkeyset restore userkeys (oldset) hkeyset t oldset;

#### **Parameters**

oldset

Specifies the previous hardware keyset returned by the hkeyset update userkeys kernel service.

# **Description**

The hkeyset\_restore\_userkeys kernel service is a specialized protection gate that restores only the user-mode portion of the current hardware keyset. This is normally done by the kernel after this kernel service accesses user memory.

### **Execution Environment**

The hkeyset\_restore\_userkeys kernel service can be called from the process environment only.

### **Return Values**

EINVAL\_HKEYSET\_RESTORE\_USERKEYS

Indicates a successful completion.

Indicates that the execution environment is not valid.

### **Related Information**

The hkeyset update userkeys kernel service.

## hkeyset update userkeys Kernel Service

## Purpose

Establishes accessibility to user memory.

## **Syntax**

#include <sys/skeys.h>

kerrno t hkeyset update userkeys (oldset) hkeyset t \*oldset;

#### **Parameters**

oldset

Contains the returned previous hardware keyset. The valid parameter must be an 8-byte aligned address.

## **Description**

The hkeyset\_update\_userkeys kernel service is a specialized protection gate that alters only the user-mode portion of the current hardware keyset. The user-mode storage keys for the currently running thread is placed into the current hardware keyset. This is normally done by the kernel when this kernel service accesses user memory.

The previous hardware keyset is returned in the memory specified by the oldset parameter. You can use the **hkeyset restore userkeys** kernel service to remove the user accessibility when it is no longer needed.

Important: Kernel services such as xmemin, xmemout, uiomove, copyin, and coypout are the suggested ways to access user memory from the kernel. If possible, avoid using kernel code to directly access user memory.

### **Execution Environment**

The **hkeyset update userkeys** kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful completion.

EINVAL\_HKEYSET\_UPDATE\_USERKEYS

Indicates that the parameter or execution environment is not valid

### **Related Information**

The hkeyset\_restore\_userkeys kernel service, xmemin kernel service, xmemout kernel service, uiomove kernel service, copyin kernel service, copyout kernel service.

## i\_clear Kernel Service

## **Purpose**

Removes an interrupt handler.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/intr.h>
void i clear ( handler)
struct intr *handler:
```

### **Parameter**

handler

Specifies the address of the interrupt handler structure passed to the i\_init service.

## **Description**

The i\_clear service removes the interrupt handler specified by the handler parameter from the set of interrupt handlers that the kernel knows about. "Coding an Interrupt Handler" in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts contains a brief description of interrupt handlers.

The i mask service is called by the i clear service to disable the interrupt handler's bus interrupt level when this is the last interrupt handler for the bus interrupt level. The i clear service removes the interrupt handler structure from the list of interrupt handlers. The kernel maintains this list for that bus interrupt level.

### **Execution Environment**

The i\_clear kernel service can be called from the process environment only.

#### **Return Values**

The i clear service has no return values.

### Related Information

The i init kernel service.

I/O Kernel Services, Understanding Interrupts in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## i disable Kernel Service

# **Purpose**

Disables interrupt priorities.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/intr.h>
```

```
int i_disable ( new)
int new;
```

#### **Parameter**

Specifies the new interrupt priority.

## **Description**

Attention: The i disable service has two side effects that result from the replaceable and pageable nature of the kernel. First, it prevents process dispatching. Second, it ensures, within limits, that the caller's stack is in memory. Page faults that occur while the interrupt priority is not equal to INTBASE crash the system.

**Note:** The **i disable** service is very similar to the standard UNIX<sup>®</sup> **spl** service.

The i disable service sets the interrupt priority to a more favored interrupt priority. The interrupt priority is used to control which interrupts are allowed.

A value of INTMAX is the most favored priority and disables all interrupts. A value of INTBASE is the least favored and disables only interrupts not in use. The /usr/include/sys/intr.h file defines valid interrupt priorities.

The interrupt priority is changed only to serialize code executing in more than one environment (that is, process and interrupt environments).

For example, a device driver typically links requests in a list while executing under the calling process. The device driver's interrupt handler typically uses this list to initiate the next request. Therefore, the device driver must serialize updating this list with device interrupts. The i disable and i enable services provide this ability. The **I\_init** kernel service contains a brief description of interrupt handlers.

Note: When serializing such code in a multiprocessor-safe kernel extension, locking must be used as well as interrupt control. For this reason, new code should call the disable\_lock kernel service instead of i disable. The disable lock service performs locking only on multiprocessor systems, and helps ensure that code is portable between uniprocessor and multiprocessor systems.

The i\_disable service must always be used with the i\_enable service. A routine must always return with the interrupt priority restored to the value that it had upon entry.

The i mask service can be used when a routine must disable its device across a return.

Because of these side effects, the caller of the i disable service should ensure that:

- · The reference parameters are pinned.
- The code executed during the disable operation is pinned.
- The amount of stack used during the disable operation is less than 1KB.
- The called programs use less than 1KB of stack.

In general, the caller of the i\_disable service should also call only services that can be called by interrupt handlers. However, processes that call the i\_disable service can call the e\_sleep, e\_wait, e\_sleepl, lockl, and unlockl services as long as the event word or lockword is pinned.

The kernel's first-level interrupt handler sets the interrupt priority for an interrupt handler before calling the interrupt handler. The interrupt priority for a process is set to INTBASE when the process is created and is part of each process's state. The dispatcher sets the interrupt priority to the value associated with the process to be executed.

### **Execution Environment**

The i\_disable kernel service can be called from either the process or interrupt environment.

#### **Return Value**

The i disable service returns the current interrupt priority that is subsequently used with the i enable service.

#### **Related Information**

The disable lock kernel service, i enable kernel service, i mask kernel service.

I/O Kernel Services, Understanding Execution Environments, Understanding Interrupts in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### i enable Kernel Service

## Purpose

Enables interrupt priorities.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/intr.h>
void i_enable ( old)
int old:
```

#### **Parameter**

Specifies the interrupt priority returned by the i\_disable service.

# **Description**

The i enable service restores the interrupt priority to a less-favored value. This value should be the value that was in effect before the corresponding call to the **i\_disable** service.

Note: When serializing a thread with an interrupt handler in a multiprocessor-safe kernel extension, locking must be used as well as interrupt control. For this reason, new code should call the unlock enable kernel service instead of i enable. The unlock enable service performs locking only on multiprocessor systems, and helps ensure that code is portable between uniprocessor and multiprocessor systems.

#### **Execution Environment**

The i enable kernel service can be called from either the process or interrupt environment.

#### Return Values

The i enable service has no return values.

#### **Related Information**

The i disable kernel service, unlock enable kernel service.

Understanding Interrupts, I/O Kernel Services, Understanding Execution Environments in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## i eoi Kernel Service

## **Purpose**

Issues an End of Interrupt (EOI) for a given handler.

# **Syntax**

```
int i eoi(struct intr *handler)
```

## **Description**

The i eoi kernel service allows a device driver to issue an End of Interrupt (EOI) for its device explicitly. For level-triggered interrupts, after the second level interrupt handler (SLIH) has completed, the kernel issues an EOI on behalf of the device driver. For ISA (8259) edge-triggered interrupts, the kernel issues the EOI on behalf of the device driver before calling the SLIH. However, in the case of some edge-triggered interrupts (for example, PCI and PCI-E style edge-triggered interrupt), it is desirable that the device driver checks for pending work before the EOI is issued, and the driver is required to check for any additional work after the EOI is issued. The i\_eoi kernel service facilitates such operations and issues an EOI for an edge-triggered interrupt source. The i\_eoi kernel service fails if called for a level-triggered interrupt source.

#### **Parameters**

handler Pointer to the interrupt handler

### **Execution Environment**

The **i eoi** kernel service can be called from process or interrupt environment.

### Return Values

INTR SUCC if successful

INTR FAIL if unsuccessful (the INTR EDGE flag was not set on i init()).

Virtual device drivers' interrupt services are similar to the PCI interrupt services. Interrupts are registered with a bus\_type of BUS\_BID. The primary difference is that the edge flag should be set for vdevices. For example:

```
Parent CuDv "bus id" VDEVICE bus BID
Device CuAt "bus_intr_lvl" Adapter interrupt level
intr.flags |= INTR EDGE
intr.bus type = BUS BID
intr.bid = Parent CuDv.bus id
intr.level = Device CuAt.bus intr lvl
```

PCI-E interrupts are Message Signalled Interrupts, and hence, they are edge-triggered. Therefore, INTR EDGE flag should be specified.

# ifa\_ifwithaddr Kernel Service

# **Purpose**

Locates an interface based on a complete address.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/socket.h>
#include <net/if.h>
#include <net/af.h>
struct ifaddr * ifa_ifwithaddr ( addr)
struct sockaddr *addr;
```

#### **Parameter**

addr Specifies a complete address.

## **Description**

The **ifa ifwithaddr** kernel service is passed a complete address and locates the corresponding interface. If successful, the ifa\_ifwithaddr service returns the ifaddr structure associated with that address.

#### **Execution Environment**

The ifa\_ifwithaddr kernel service can be called from either the process or interrupt environment.

### **Return Values**

If successful, the ifa ifwithaddr service returns the corresponding ifaddr structure associated with the address it is passed. If no interface is found, the ifa ifwithaddr service returns a null pointer.

## Example

To locate an interface based on a complete address, invoke the ifa ifwithaddr kernel service as follows: ifa ifwithaddr((struct sockaddr \*)&ipaddr);

#### **Related Information**

The ifa ifwithdstaddr kernel service, ifa ifwithnet kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# ifa ifwithdstaddr Kernel Service

# **Purpose**

Locates the point-to-point interface with a given destination address.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/socket.h>
#include <net/if.h>
struct ifaddr * ifa ifwithdstaddr ( addr)
struct sockaddr *addr;
```

### **Parameter**

addr

Specifies a destination address.

## **Description**

The ifa\_ifwithdstaddr kernel service searches the list of point-to-point addresses per interface and locates the connection with the destination address specified by the *addr* parameter.

### **Execution Environment**

The ifa withdstaddr kernel service can be called from either the process or interrupt environment.

#### **Return Values**

If successful, the ifa\_ifwithdstaddr service returns the corresponding ifaddr structure associated with the point-to-point interface. If no interface is found, the ifa ifwithdstaddr service returns a null pointer.

## Example

To locate the point-to-point interface with a given destination address, invoke the ifa ifwithdstaddr kernel service as follows:

ifa ifwithdstaddr((struct sockaddr \*)&ipaddr);

### **Related Information**

The ifa\_ifwithaddr kernel service, ifa\_ifwithnet kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## ifa\_ifwithnet Kernel Service

# Purpose

Locates an interface on a specific network.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/socket.h>
#include <net/if.h>
struct ifaddr * ifa ifwithnet ( addr)
register struct sockaddr *addr;
```

### **Parameter**

addr Specifies the address.

# **Description**

The ifa\_ifwithnet kernel service locates an interface that matches the network specified by the address it is passed. If more than one interface matches, the ifa\_ifwithnet service returns the first interface found.

### **Execution Environment**

The ifa ifwithnet kernel service can be called from either the process or interrupt environment.

#### **Return Values**

If successful, the ifa ifwithnet service returns the ifaddr structure of the correct interface. If no interface is found, the ifa\_ifwithnet service returns a null pointer.

## **Example**

To locate an interface on a specific network, invoke the ifa\_ifwithnet kernel service as follows: ifa ifwithnet((struct sockaddr \*)&ipaddr);

### **Related Information**

The ifa ifwithaddr kernel service, ifa ifwithdstaddr kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## if attach Kernel Service

## **Purpose**

Adds a network interface to the network interface list.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>
if_attach ( ifp)
struct ifnet *ifp;
```

#### **Parameter**

Points to the interface network (ifnet) structure that defines the network interface.

# **Description**

The if attach kernel service registers a Network Interface Driver (NID) in the network interface list.

#### **Execution Environment**

The **if attach** kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The **if attach** kernel service has no return values.

#### **Related Information**

The if detach kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## if\_detach Kernel Service

## **Purpose**

Deletes a network interface from the network interface list.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>
if detach ( ifp)
struct ifnet *ifp;
```

### **Parameter**

Points to the interface network (ifnet) structure that describes the network interface to delete. ifp

## **Description**

The if\_detach kernel service deletes a Network Interface Driver (NID) entry from the network interface list.

### **Execution Environment**

The if detach kernel service can be called from either the process or interrupt environment.

#### **Return Values**

Indicates that the network interface was successfully deleted.

**ENOENT** Indicates that the if detach kernel service could not find the NID in the network interface list.

### **Related Information**

The if attach kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## if down Kernel Service

# **Purpose**

Marks an interface as down.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <net/if.h> void if\_down ( ifp) register struct ifnet \*ifp;

### **Parameter**

Specifies the **ifnet** structure associated with the interface array.

## **Description**

The if down kernel service:

- Marks an interface as down by setting the flags field of the ifnet structure appropriately.
- · Notifies the protocols of the transaction.
- · Flushes the output queue.

The ifp parameter specifies the **ifnet** structure associated with the interface as the structure to be marked as down.

### **Execution Environment**

The if\_down kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The if down service has no return values.

## **Example**

To mark an interface as down, invoke the if down kernel service as follows: if down(ifp);

#### **Related Information**

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## if nostat Kernel Service

# **Purpose**

Zeroes statistical elements of the interface array in preparation for an attach operation.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>
void if nostat ( ifp)
struct ifnet *ifp;
```

#### **Parameter**

ifp Specifies the **ifnet** structure associated with the interface array.

# **Description**

The **if nostat** kernel service zeroes the statistic elements of the **ifnet** structure for the interface. The *ifp* parameter specifies the ifnet structure associated with the interface that is being attached. The if nostat service is called from the interface attach routine.

### **Execution Environment**

The **if nostat** kernel service can be called from either the process or interrupt environment.

### **Return Values**

The **if nostat** service has no return values.

## **Example**

To zero statistical elements of the interface array in preparation for an attach operation, invoke the if\_nostat kernel service as follows:

```
if nostat(ifp);
```

### **Related Information**

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### ifunit Kernel Service

## **Purpose**

Returns a pointer to the **ifnet** structure of the requested interface.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>
struct ifnet *
ifunit ( name)
char *name;
```

#### **Parameter**

Specifies the name of an interface (for example, en0).

# **Description**

The **ifunit** kernel service searches the list of configured interfaces for an interface specified by the *name* parameter. If a match is found, the ifunit service returns the address of the ifnet structure for that interface.

#### **Execution Environment**

The **ifunit** kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The ifunit kernel service returns the address of the ifnet structure associated with the named interface. If the interface is not found, the service returns a null value.

# **Example**

To return a pointer to the ifnet structure of the requested interface, invoke the ifunit kernel service as follows:

```
ifp = ifunit("en0");
```

### **Related Information**

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### i init Kernel Service

## **Purpose**

Defines an interrupt handler.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/intr.h>
int i_init
( handler)
struct intr *handler:
```

#### **Parameter**

handler Designates the address of the pinned interrupt handler structure.

## **Description**

Attention: The interrupt handler structure must not be altered between the call to the i init service to define the interrupt handler and the call to the i clear service to remove the interrupt handler. The structure must also stay pinned. If this structure is altered at those times, a kernel panic may result.

The i\_init service allows device drivers to define an interrupt handler to the kernel. The interrupt handler intr structure pointed to by the handler parameter describes the interrupt handler. The caller of the i init service must initialize all the fields in the intr structure. The /usr/include/sys/intr.h file defines these fields and their valid values.

The i init service enables interrupts by linking the interrupt handler structure to the end of the list of interrupt handlers defined for that bus level. If this is the first interrupt handler for the specified bus interrupt level, the i init service enables the bus interrupt level by calling the i unmask service.

The interrupt handler can be called before the i\_init service returns if the following two conditions are met:

- The caller of the i init service is executing at a lower interrupt priority than the one defined for the interrupt.
- An interrupt for the device or another device on the same bus interrupt level is already pending.

On multiprocessor systems, all interrupt handlers defined with the i init kernel service run by default on the first processor started when the system was booted. This ensures compatibility with uniprocessor interrupt handlers. If the interrupt handler being defined has been designed to be multiprocessor-safe, or is an EPOW (Early Power-Off Warning) or off-level interrupt handler, set the INTR MPSAFE flag in the flags field of the intr structure passed to the i init kernel service. The interrupt handler will then run on any available processor.

### Coding an Interrupt Handler

The kernel calls the interrupt handler when an enabled interrupt occurs on that bus interrupt level. The interrupt handler is responsible for determining if the interrupt is from its own device and processing the interrupt. The interface to the interrupt handler is as follows:

int interrupt\_handler (handler) struct intr \*handler;

The handler parameter points to the same interrupt handler structure specified in the call to the i\_init kernel service. The device driver can pass additional parameters to its interrupt handler by declaring the interrupt handler structure to be part of a larger structure that contains these parameters.

The interrupt handler can return one of two return values. A value of INTR\_SUCC indicates that the interrupt handler processed the interrupt and reset the interrupting device. A value of INTR\_FAIL indicates that the interrupt was not from this interrupt handler's device.

### Registering Early Power-Off Warning (EPOW) Routines

The i init kernel service can also be used to register an EPOW (Early Power-Off Warning) notification routine.

The return value from the EPOW interrupt handler should be INTR SUCC, which indicates that the interrupt was successfully handled. All registered EPOW interrupt handlers are called when an EPOW interrupt is indicated.

### **Execution Environment**

The i init kernel service can be called from the process environment only.

#### Return Values

INTR\_SUCC Indicates a successful completion.

INTR\_FAIL Indicates an unsuccessful completion. The i\_init service did not define the interrupt handler.

> An unsuccessful completion occurs when there is a conflict between a shared and a nonshared bus interrupt level. An unsuccessful completion also occurs when more than one interrupt priority is assigned to a bus interrupt level.

#### **Related Information**

Understanding Interrupts, I/O Kernel Services, in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## i mask Kernel Service

## **Purpose**

Disables a bus interrupt level.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/intr.h>

```
void i_mask ( handler)
struct intr *handler;
```

#### **Parameter**

handler Specifies the address of the interrupt handler structure that was passed to the i init service.

## **Description**

The i mask service disables the bus interrupt level specified by the handler parameter.

The i disable and i enable services are used to serialize the execution of various device driver routines with their device interrupts.

The i\_init and i\_clear services use the i\_mask and i\_unmask services internally to configure bus interrupt levels.

Device drivers can use the i\_disable, i\_enable, i\_mask, and i\_unmask services when they must perform off-level processing with their device interrupts disabled. Device drivers also use these services to allow process execution when their device interrupts are disabled.

### **Execution Environment**

The i mask kernel service can be called from either the process or interrupt environment.

### **Return Values**

The i mask service has no return values.

#### **Related Information**

The i unmask kernel service.

Understanding Interrupts, I/O Kernel Services, in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# init\_heap Kernel Service

# **Purpose**

Initializes a new heap to be used with kernel memory management services.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmalloc.h>
#include <sys/malloc.h>
heapaddr t init heap ( area, size, heapp)
caddr t area;
int size;
heapaddr_t *heapp;
```

#### **Parameters**

Specifies the virtual memory address used to define the starting memory area for the heap. This address area must be page-aligned.

size Specifies the size of the heap in bytes. This value must be an integral number of system pages. Points to the external heap descriptor. This must have a null value. The base kernel uses this field is used heapp

to specify special heap characteristics that are unavailable to kernel extensions.

# **Description**

The init\_heap kernel service is most commonly used by a kernel process to initialize and manage an area of virtual memory as a private heap. Once this service creates a private heap, the returned heapaddr\_t value can be used with the xmalloc or xmfree service to allocate or deallocate memory from the private heap. Heaps can be created within other heaps, a kernel process private region, or even on a stack.

Few kernel extensions ever require the init\_heap service because the exported global kernel\_heap and pinned\_heap are normally used for memory allocation within the kernel. However, kernel processes can use the init\_heap service to create private nonglobal heaps within their process private region for controlling kernel access to the heap and possibly for performance considerations.

#### **Execution Environment**

The **init** heap kernel service can be called from the process environment only.

#### **Related Information**

The **xmalloc** kernel service. **xmfree** kernel service.

Memory Kernel Services and Using Kernel Processes in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## initp Kernel Service

# **Purpose**

Changes the state of a kernel process from idle to ready.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int initp
(pid, func, init parms,
parms length, name)
pid_t pid;
void (func) (int
flag, void* init_parms, int parms_length );
void * init parms;
int parms length;
char * name;
```

#### **Parameters**

Specifies the process identifier of the process to be initialized. pid

Specifies the process's initialization routine. func

Specifies the pointer to the initialization parameters. init\_parm Specifies the length of the initialization parameters. parms\_length

name Specifies the process name.

## **Description**

The **initp** kernel service completes the transition of a kernel process from idle to ready. The idle state for a process is represented by **p\_status == SIDL**. Before calling the **initp** service, the **creatp** service is called to create the process. The creatp service allocates and initializes a process table entry.

The initp service creates and initializes the process-private segment. The process is marked as a kernel process by a bit set in the p\_flag field in the process table entry. This bit, the SKPROC bit, signifies that the process is a kernel process.

The process calling the initp service to initialize a newly created process must be the same process that called the **creatp** service to create the new process.

"Using Kernel Processes" in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts further explains how the initp kernel service completes the initialization process begun by the creatp service.

The pid parameter identifies the process to be initialized. It must be valid and identify a process in the SIDL (idle) state.

The name parameter points to a character string that names the process. The leading characters of this string are copied to the user structure. The number of characters copied is implementation-dependent, but at least four are always copied.

The *func* parameter indicates the main entry point of the process. The new process is made ready to run this function. If the init\_parms parameter is not null, it points to data passed to this routine. The parameter structure must be agreed upon between the initializing and initialized process. The initp service copies the data specified by the init parm parameter (with the exact number of bytes specified by the parms length parameter) of data to the new process's stack.

#### **Execution Environment**

The initp kernel service can be called from the process environment only.

# Example

To initialize the kernel process running the function *main\_kproc*, enter:

```
pid = creatp();
initp(pid, main kproc, &node num, sizeof(int), "tkproc");
main kproc(int flag, void* init parms, int parms length)
        i = *( (int *)init parms );
}
```

### **Return Values**

Indicates a successful operation.

**ENODEV** The process could not be scheduled because it has a processor attachment that does not contain any

available processors. This can be caused by Dynamic Processor Deallocation.

**ENOMEM** Indicates that there was insufficient memory to initialize the process.

**EINVAL** Indicates an pid parameter that was not valid.

### **Related Information**

The creatp kernel service.

The **func** subroutine.

Introduction to Kernel Processes, Process and Exception Management Kernel Services, and Dynamic logical partitioning in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# initp Kernel Service func Subroutine

## **Purpose**

Directs the process initialization routine.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
void func (flag, init_parms, parms_length)
int flag;
void * init parms;
int parms length;
```

### **Parameters**

Specifies the process's initialization routine. func

Has a 0 value if this subroutine is executed as a result of initializing a process with the initp flag

init\_parms Specifies the pointer to the initialization parameters. parms\_length Specifies the length of the initialization parameters.

### **Related Information**

The initp kernel service.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# io\_map Kernel Service

# **Purpose**

Attach to an I/O mapping

## **Syntax**

#include <sys/adspace.h> void \* io map (io handle) io\_handle\_t io handle;

## **Description**

The io map kernel service sets up addressibility to the I/O address space defined by the io handle t structure. It returns an effective address representing the start of the mapped region.

The io map kernel service is a replacement call for the iomem att kernel service, which is deprecated on AIX<sup>®</sup> 6.1. However, the io map kernel service might replace multiple iomem att calls depending on the device, the driver, and whether multiple regions were mapped into a single virtual segment. Like the iomem att kernel service, this service does not return any kind of failure. If something goes wrong, the system crashes.

There is a major difference between io map and iomem att. iomem att took an io map structure containing a bus address and returned a fully qualified effective address with any byte offset from the bus address preserved and computed into the returned effective address. The io map kernel service always returns a segment-aligned effective address representing the beginning of the I/O segment corresponding to io\_handle\_t. Manipulation of page and byte offsets within the segment are responsibilities of the device driver.

The io\_map kernel service is subject to nesting rules regarding the number of attaches allowed. A total system number of active temporary attaches is 4. However, it is recommended that no more than one active attach be owned by a driver calling the interrupt or DMA kernel services. It is also recommended that no active attaches be owned by a driver when calling other kernel services.

### **Parameters**

io handle

Received on a prior successful call to io\_map\_init. Describes the I/O space to attach to.

#### **Execution Environment**

The io map kernel service can be called from the process or interrupt environment.

### **Return Values**

The **io** map kernel service returns a segment-aligned effective address to access the I/O address spaces.

#### **Related Information**

"io\_map\_init Kernel Service" on page 219, "io\_map\_clear Kernel Service," and "io\_unmap Kernel Service" on page 220.

Programmed I/O (PIO) Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# io map clear Kernel Service

# **Purpose**

Removes an I/O mapping segment.

## **Syntax**

```
#include <sys/adspace.h>
void io map clear (io handle)
io_handle_t io handle;
```

## Description

This service destroys all mappings defined by the *io handle t* parameter.

There should be no active mappings (outstanding io map calls) to this handle when io map clear is called. The segment previously created by an io map init call or multiple io map init calls, is deleted.

#### **Parameters**

io handle

Received on a prior successful call to io\_map\_init. Describes the I/O space to be removed.

### **Execution Environment**

The io map clear kernel service can be called from the process environment only.

### **Related Information**

"io map init Kernel Service," "io map Kernel Service" on page 217, and "io unmap Kernel Service" on page 220.

Programmed I/O (PIO) Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# io\_map\_init Kernel Service

# **Purpose**

Creates and initializes an I/O mapping segment.

# **Syntax**

```
#include <sys/adspace.h>
#include <sys/vm_types.h>
io_handle_t io_map_init (io_map_ptr, page_offset, io_handle)
struct io map *io_map_ptr;
vpn_t page offset;
io_handle_t io_handle;
struct io map {
                                         /* structure version number */
/* flags for mapping */
        int key;
        int flags;
        int J tags,
int32long64_t size;
                                        /* size of address space needed */
                                          /* bus ID */
        int bid;
        long long busaddr;
                                         /* bus address */
};
```

# **Description**

The io\_map\_init kernel service will create a segment to establish a cache-inhibited virtual-to-real translation for the bus address region defined by the contents of the io\_map struct. The flags parameter of the io map structure can be used to customize the mapping such as making the region read-only, using the IOM RDONLY flag.

The io map init kernel service returns a handle of an opaque type io handle t to be used on future io map or io unmap calls. All services that use the io handle returned by io map init must use the handle from the most recent call. Using an old handle is a programming error.

The *vpn\_t* type parameter represents the virtual page number offset to allow the caller to specify where, in the virtual segment, to map this region. The offset must not conflict with a previous mapping in the segment. The caller should map the most frequently accessed and performance critical I/O region at vpn\_t offset 0 into the segment. This is due to the fact that the subsequent io\_map calls using this io\_handle will return an effective address representing the start of the segment (that is, page offset 0). The device driver is responsible for managing various offsets into the segment. A single bus memory address page can be mapped multiple times at different *vpn\_t* offsets within the segment.

The io\_handle\_t parameter is useful when the caller wants to append a new mapping to an existing segment. For the initial creation of a new I/O segment, this parameter must be NULL. For appended mappings to the same segment, this parameter is the io\_handle\_t returned from the last successful io map init call. If the mapping fails for any reason (offset conflicts with prior mapping, or no more room in the segment), NULL is returned. In this case, the previous io handle t is still valid. If successful, the io handle t returned should be used on all future calls. In this way, a device driver can manage multiple I/O address spaces of a single adapter within a single virtual address segment, requiring the driver to do only a single attach, io\_map, to gain addressibility to all of the mappings.

### **Parameters**

io\_map\_ptr Pointer to io\_map structure describing the address region

page\_offset

Page offset at which to map the specified region into the

virtual address segment. io handle

For the first call, this parameter should be NULL. When adding to an existing mapping, this parameter is the io\_handle received on a prior successful call to

io\_map\_init.

#### **Execution Environment**

The io\_map\_init kernel service can be called from the process environment only.

#### **Return Values**

An opaque handle to the mapped I/O segment in the virtual memory that must be used in io\_handle\_t

subsequent calls to this service.

NULL Failed to create or append mapping.

#### **Related Information**

"io\_map\_clear Kernel Service" on page 218, "io\_map Kernel Service" on page 217, and "io\_unmap Kernel Service."

Programmed I/O (PIO) Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# io unmap Kernel Service

# **Purpose**

Detach from an I/O mapping

## **Syntax**

```
#include <sys/adspace.h>
void io unmap (eaddr)
void *eaddr;
```

## Description

The io unmap kernel service removes addressibility to the I/O address space defined by the eaddr parameter. There must be a valid active mapping from a previous io\_map call for this effective address. The eaddr parameter can be any valid effective address within the segment, and it does not have to be exactly the same as the address returned by io map.

The io unmap kernel service is a replacement call for the iomem det kernel service, which is deprecated on AIX® 6.1. However, the io unmap kernel service might replace multiple iomem det calls depending on the device, the driver, and whether multiple regions were mapped into a single virtual segment using the io map init kernel service.

#### **Parameters**

eaddr

Received on a prior successful call to io\_map. Effective address for the I/O space to detach from.

#### **Execution Environment**

The io unmap kernel service can be called from the process or interrupt environment.

#### Related Information

"io\_map\_init Kernel Service" on page 219, "io\_map\_clear Kernel Service" on page 218, and "io\_map Kernel Service" on page 217.

Programmed I/O (PIO) Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### iodone Kernel Service

# **Purpose**

Performs block I/O completion processing.

# **Syntax**

```
#include <sys/types.h>
#include <svs/errno.h>
#include <sys/buf.h>
void iodone ( bp)
struct buf *bp;
```

#### **Parameter**

bp Specifies the address of the buf structure for the buffer whose I/O has completed.

On a platform that supports storage keys, the passed in bp parameter must be in the KKEY\_PUBLIC or KKEY\_BLOCK\_DEV protection domain.

## **Description**

A device driver calls the **iodone** kernel service when a block I/O request is complete. The device driver must not reference or alter the buffer header or buffer after calling the iodone service.

The iodone service takes one of two actions, depending on the current interrupt level. Either it invokes the caller's individual **iodone** routine directly, or it schedules I/O completion processing for the buffer to be performed off-level, at the INTIODONE interrupt level. The interrupt handler for this level then calls the iodone routine for the individual device driver. In either case, the individual iodone routine is defined by the b iodone buffer header field in the buffer header. This iodone routine is set up by the caller of the device's strategy routine.

For example, the file I/O system calls set up a routine that performs buffered I/O completion processing. The **uphysio** service sets up a routine that performs raw I/O completion processing. Similarly, the pager sets up a routine that performs page-fault completion processing.

### Setting up an iodone Routine

Under certain circumstances, a device driver can set up an iodone routine. For example, the logical volume device driver can follow this procedure:

- 1. Take a request for a logical volume.
- 2. Allocate a buffer header.
- 3. Convert the logical volume request into a physical volume request.
- 4. Update the allocated buffer header with the information about the physical volume request. This includes setting the b iodone buffer header field to the address of the individual iodone routine.
- 5. Call the physical volume device driver strategy routine. Here, the caller of the logical volume strategy routine has set up an iodone routine that is started when the logical volume request is complete. The logical volume strategy routine in turn sets up an iodone routine that is invoked when the physical volume request is complete.

The key point of this example is that only the caller of a strategy routine can set up an iodone routine and even then, this can only be done while setting up the request in the buffer header.

The interface for the **iodone** routine is identical to the interface to the **iodone** service.

#### **Execution Environment**

The **iodone** kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The iodone service has no return values.

#### **Related Information**

The iowait kernel service.

The **buf** structure.

Understanding Interrupts and I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### iostadd Kernel Service

## **Purpose**

Registers an I/O statistics structure used for updating I/O statistics reported by the iostat subroutine.

## Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/iostat.h>
#include <sys/devinfo.h>
int iostadd ( devtype, devstatp)
int devtype;
union {
       struct ttystat *ttystp;
       struct dkstat *dkstp;
       } devstatp;
```

## **Description**

The iostadd kernel service is used to register the I/O statistics structure required to maintain statistics on a device. The iostadd service is typically called by a tty, disk, or CD-ROM device driver to provide the statistical information used by the iostat subroutine. The iostat subroutine displays statistic information for tty and disk devices on the system. The iostadd service should be used once for each configured device.

In AIX® 5.2, support for Multi-Path I/O (MPIO) was added to the iostadd kernel service and the dkstat structure. The dkstat structure was expanded to accomodate the MPIO data. The iostadd kernel service was modified to handle the new version of the dkstat structure as well as older, legacy versions. For an MPIO device, the anchor is the disk's **dkstat** structure. This must be the first **dkstat** structure registered using the iostadd kernel service. Any path dkstat structures that are registered subsequently must reference the address of the anchor dkstat (disk) structure in the dkstat.dk mpio anchor field.

For tty devices, the devtype parameter has a value of **DD tty**. In this case, the **iostadd** service uses the devstatp parameter to return a pointer to a ttystat structure.

For disk or CD-ROM devices with a devtype value of DD DISK or DD CD-ROM, the caller must provide a pinned and initialized dkstat structure as an input parameter. This structure is pointed to by the devstatp parameter on entry to the iostadd kernel service.

If the device driver support for a device is terminated, the dkstat or ttystat structure registered with the iostadd kernel service should be deregistered by calling the iostdel kernel service.

#### I/O Statistics Structures

The iostadd kernel service uses two structures that are found in the usr/include/sys/iostat.h file: the ttystat structure and the dkstat structure.

The **ttystat** structure contains the following tty-related fields:

Field	Description
rawinch	Count of raw characters received by the tty device
caninch	Count of canonical characters generated from canonical processing
outch	Count of the characters output to a tty device

The second structure used by the iostadd kernel service is the dkstat structure, which contains information about disk devices. This structure contains the following fields:

Field	Description
diskname	32-character string name for the disk's logical device
dknextp	Pointer to the next dkstat structure in the chain
dk_status	Disk entry-status flags

Field Description

dk time Time the disk is active dk bsize Number of bytes in a block

dk xfers Number of transfers to or from the disk dk rblks Number of blocks read from the disk dk wblks Number of blocks written to the disk dk\_seeks Number of seek operations for disks dk version Version of the dkstat structure

dk q depth Que depth

dk mpio anchor Pointer to the path data anchor (disk)

Pointer to the next path dkstat structure in the chain dk mpio next path

dk\_mpio\_path\_id

### tty Device Driver Support

The rawinch field in the ttystat structure should be incremented by the number of characters received by the tty device. The caninch field in the ttystat structure should be incremented by the number of input characters generated from canonical processing. The outch field is increased by the number of characters output to tty devices. These fields should be incremented by the device driver, but never be cleared.

### Disk Device Driver Support

A disk device driver must perform these four tasks:

- Allocate and pin a dkstat structure during device initialization.
- Update the dkstat.diskname field with the device's logical name.
- Update the dkstat.dk bsize field with the number of bytes in a block on the device.
- Set all other fields in the structure to 0.

If a disk device driver supports MPIO, it must perform the following tasks:

- Allocate and pin a dkstat structure during device initialization.
- Update the dkstat.diskname field with the device's logical name.
- Update the dkstat.dk bsize field with the number of bytes in a block on the device.
- Set the value of dkstat.dk version to dk\_qd\_mpio\_magic.
- Set the value of dkstat.dk mpio anchor to 0 if the dkstat structure being added is the disk.
- · Set the value of dkstat.dk mpio anchor to the address of the path's anchor (disk) dkstat structure, and set dkstat.dk mpio path id to the path's ID if the dkstat structure being added is a path.
- · Set all other fields to 0.

If the device supports discrete seek commands, the dkstat.dk xrate field in the structure should be set to the transfer rate capability of the device (KB/sec). The device's dkstat structure should then be registered using the iostadd kernel service.

During drive operation update, the dkstat.dk status field should show the busy/nonbusy state of the device. This can be done by setting and resetting the IOST\_DK\_BUSY flag. The dkstat.dk xfers field should be incremented for each transfer initiated to or from the device. The dkstat.dk rblks and dkstat.dk wblks fields should be incremented by the number of blocks read or written.

If the device supports discrete seek commands, the dkstat.dk seek field should be incremented by the number of seek commands sent to the device. If the device does not support discrete seek commands, both the dkstat.dk seek and dkstat.dk xrate fields should be left with a value of 0.

The base kernel updates the dkstat.dk nextp and dkstat.dk time fields. They should not be modified by the device driver after initialization. For MPIO devices, the base kernel also updates the dkstat.dk\_mpio\_next\_path field.

**Note:** The same **dkstat** structure must not be registered more than once.

In addition to basic tasks, a disk driver must perform the following tasks before calling the iostadd kernel service if the driver supports the **-D** option of the **iostat** command:

- Set the value of dkstat.dk version to dk\_qd\_service2\_magic.
- Set the dkstat.ident.adapter field to the adapter name if the driver does not support MPIO.

During I/O operations, the driver must perform the following tasks:

- Increase the dkstat.\_\_dk\_rxfers field for each read transfer.
- Update the dkstat.dk q depth field with the number of I/O requests which are in progress.
- Increase the dkstat.dk q full field when the number of I/O requests which are in progress reaches the maximum queue depth.
- Increase the dkstat.dk rserv field by the service time which is the delta-time base value between when the devstrat kernel service sends a read request to the adapter driver and when the iodone kernel service returns the request from the adapter driver.
- Increase the dkstat.dk rtimeout field when the driver retries a failed read request.
- Increase the dkstat.dk rfailed field when the driver returns a failed read request as an error.
- Update the dkstat.dk min rserv field with the minimum service time for a read request.
- · Update the dkstat.dk max rserv field with the maximum service time for a read request.
- Increase the dkstat.dk wserv field by the service time which is the delta-time base value between when the devstrat kernel service sends a write request to the adapter driver and when the iodone kernel service returns the request from the adapter driver.
- Increase the dkstat.dk wtimeout field when the driver retries a failed write request.
- Increase the dkstat.dk wfailed field when the driver returns a failed write request as an error.
- Update the dkstat.dk min wserv field with the minimum service time for a write request.
- Update the dkstat.dk max wserv field with the maximum service time for a write request.
- Increase and decrease the dkstat.dk wq depth field when the driver enqueues and dequeues an I/O request.
- Increase the dkstat.dk wq time field by the wait time which is the delta-time base value between when the driver enqueues an I/O request and when the devstrat kernel service sends the request to the adapter driver.
- Update the dkstat.dk wg min time field with the minimum wait time.
- Update the dkstat.dk\_wq\_max\_time field with the maximum wait time.

#### **Parameters**

devtype

Specifies the type of device for which I/O statistics are kept. The various device types are defined in the /usr/include/sys/devinfo.h file. Currently, I/O statistics are only kept for disks, CD-ROMs, and tty devices. Possible values for this parameter are:

DD DISK

For disks

DD\_CD-ROM

For CD-ROMs

DD\_TTY

For tty devices

devstatp

Points to an I/O statistics structure for the device type specified by the devtype parameter. For a devtype parameter of DD\_tty, the address of a pinned ttystat structure is returned. For a devtype parameter of DD\_DISK or DD\_CD-ROM, the parameter is an input parameter pointing to a dkstat structure previously allocated by the caller.

On a platform that supports storage keys, the passed in devstatp parameter must be in the KKEY\_PUBLIC or KKEY\_BLOCK\_DEV protection domain.

#### **Execution Environment**

The **iostadd** kernel service can be called from the process environment only.

#### **Return Values**

Indicates that no error has been detected.

**EINVAL** 

Indicates that the devtype parameter specified a device type that is not valid. For MPIO devices, indicates that an anchor for a path dkstat structure was not found.

#### **Related Information**

The iostat command.

The iostdel kernel service.

Kernel Extension and Device Driver Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

#### iostdel Kernel Service

# **Purpose**

Removes the registration of an I/O statistics structure used for maintaining I/O statistics on a particular device.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/iostat.h>
void iostdel ( devstatp)
union {
        struct ttystat *ttystp;
        struct dkstat *dkstp;
      } devstatp;
```

# **Description**

The iostdel kernel service removes the registration of an I/O statistics structure for a device being terminated. The device's ttystat or dkstat structure should have previously been registered using the iostadd kernel service. Following a return from the iostdel service, the iostat command will no longer display statistics for the device being terminated.

In AIX® 5.2, support for Multi-Path I/O (MPIO) was added to the iostdel kernel service. For an MPIO device, the anchor is the disk's dkstat structure. An anchor (disk) may have several paths associated with it. Each of these paths can have a dkstat structure registered using the iostadd kernel service. The semantics for unregistering a dkstat structure for an MPIO device are more restrictive than for a

non-MPIO device. All paths must unregister before the anchor (disk) is unregistered. If the anchor (disk) dkstat structure is unregistered before all of the paths associated with it are unregistered, the iostdel kernel service will remove the registration of the anchor (disk) dkstat structure and all remaining registered paths.

#### **Parameters**

devstatp

Points to an I/O statistics structure previously registered using the iostadd kernel service.

On a platform that supports storage keys, the passed in devstatp parameter must be in the KKEY\_PUBLIC or KKEY\_BLOCK\_DEV protection domain.

### **Execution Environment**

The iostdel kernel service can be called from the process environment only.

#### Return Values

The **iostdel** service has no return values.

### **Related Information**

The iostat command.

The iostadd kernel service.

Kernel Extension and Device Driver Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

#### iowait Kernel Service

## **Purpose**

Waits for block I/O completion.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
int iowait (bp)
struct buf *bp;
```

### **Parameter**

bp Specifies the address of the **buf** structure for the buffer with in-process I/O.

On a platform that supports storage keys, the passed in bp parameter must be in the KKEY\_PUBLIC or KKEY\_BLOCK\_DEV protection domain.

# **Description**

The iowait kernel service causes a process to wait until the I/O is complete for the buffer specified by the bp parameter. Only the caller of the strategy routine can call the iowait service. The B\_ASYNC bit in the buffer's b flags field should not be set.

The **iodone** kernel service must be called when the block I/O transfer is complete. The **buf** structure pointed to by the bp parameter must specify an iodone routine. This routine is called by the iodone interrupt handler in response to the call to the iodone kernel service. This iodone routine must call the e\_wakeup service with the bp->b events field as the event. This action awakens all processes waiting on I/O completion for the **buf** structure using the **iowait** service.

### **Execution Environment**

The iowait kernel service can be called from the process environment only.

#### **Return Values**

The **iowait** service uses the **geterror** service to determine which of the following values to return:

0 Indicates that I/O was successful on this buffer. **EIO** Indicates that an I/O error has occurred.

b error value Indicates that an I/O error has occurred on the buffer.

### **Related Information**

The **geterror** kernel service, **iodone** kernel service.

The **buf** structure.

# ip\_fltr\_in\_hook, ip\_fltr\_out\_hook, ipsec\_decap\_hook, inbound\_fw, outbound fw Kernel Service

## **Purpose**

Contains hooks for IP filtering.

# **Syntax**

```
#define FIREWALL OK
                           0 /* Accept IP packet
#define FIREWALL_NOTOK
                           1 /* Drop IP packet
#define FIREWALL_OK_NOTSEC 2 /* Accept non-encapsulated IP packet
                                  (ipsec decap hook only)
#include <sys/mbuf.h>
#include <net/if.h>
int (*ip fltr in hook)(struct mbuf **pkt, void **arg)
int (*ipsec_decap_hook)(struct mbuf **pkt, void **arg)
int (*ip_fltr_out_hook)(struct ifnet *ifp, struct mbuf **pkt, int flags)
#include <sys/types.h>
#include <sys/mbuf.h>
#include <netinet/ip var.h>
void (*inbound fw)(struct ifnet *ifp, struct mbuf *m, inbound fw args t *args)
void ipintr_noqueue_post_fw(struct ifnet *ifp, struct mbuf *m, inbound_fw_args_t *args)
inbound fw args t *inbound fw save args(inbound fw args t *args)
int (*outbound_fw)(struct ifnet *ifp, struct mbuf *m0, outbound_fw_args_t *args)
```

```
int ip output post fw( struct ifnet *ifp, struct mbuf *m\theta, outbound fw args t *args)
outbound fw args t *outbound fw save args(outbound fw args t *args)
```

#### **Parameters**

- Points to the mbuf chain containing the IP packet to be received (ip\_fltr\_in\_hook, ipsec\_decap\_hook) or pkt transmitted (ip fltr out hook). The pkt parameter may be examined and/or changed in any of the three hook functions.
- Is the address of a pointer to void that is locally defined in the function where ip\_fltr\_in\_hook and arg ipsec\_decap\_hook are called. The arg parameter is initially set to NULL, but the address of this pointer is passed to the two hook functions, ip\_fltr\_in\_hook and ipsec\_decap\_hook. The arg parameter may be set by either of these functions, thereby allowing a void pointer to be shared between them.
- Is the outgoing interface on which the IP packet will be transmitted for the <code>ip\_fltr\_out\_hook</code> function. ifp Indicates the ip output flags passed by a transport layer protocol. Valid flags are currently defined in the flags /usr/include/netinet/ip\_var.h files. See the Flags section below.

## **Description**

These routines provide kernel-level hooks for IP packet filtering enabling IP packets to be selectively accepted, rejected, or modified during reception, transmission, and decapsulation. These hooks are initially NULL, but are exported by the netinet kernel extension and will be invoked if assigned non-NULL values.

The ip\_fltr\_in\_hook routine is used to filter incoming IP packets, the ip\_fltr\_out\_hook routine filters outgoing IP packets, and the **ipsec decap hook** routine filters incoming encapsulated IP packets.

The ip fltr in hook function is invoked for every IP packet received by the host, whether addressed directly to this host or not. It is called after verifying the integrity and consistency of the IP packet. The function is free to examine or change the IP packet (pkt) or the pointer shared with ipsec decap hook (arg). The return value of the ip fltr in hook indicates whether pkt should be accepted or dropped. The return values are described in Expected Return Values below. If pkt is accepted (a return value of FIREWALL\_OK) and it is addressed directly to the host, the ipsec\_decap\_hook function is invoked next. If pkt is accepted, but is not directly addressed to the host, it is forwarded if IP forwarding is enabled. If ip fltr in hook indicates pkt should be dropped (a return value of FIREWALL NOTOK), it is neither delivered nor forwarded.

The ipsec\_decap\_hook function is called after reassembly of any IP fragments (the ip\_fltr\_in\_hook function will have examined each of the IP fragments) and is invoked only for IP packets that are directly addressed to the host. The ipsec decap hook function is free to examine or change the IP packet (pkt) or the pointer shared with **ipsec decap hook** (arg). The hook function should perform decapsulation if necessary, back into pkt and return the proper status so that the IP packet can be processed appropriately. See the Expected Return Values section below. For acceptable encapsulated IP packets (a return value of FIREWALL\_OK), the decapsulated packet is processed again by jumping to the beginning of the IP input processing loop. Consequently, the decapsulated IP packet will be examined first by ip fltr in hook and, if addressed to the host, by ipsec decap hook. For acceptable non-encapsulated IP packets (a return value of FIREWALL OK NOTSEC), IP packet delivery simply continues and pkt is processed by the transport layer. A return value of **FIREWALL NOTOK** indicates that *pkt* should be dropped.

The ip\_fltr\_out\_hook function is called for every IP packet to be transmitted, provided the outgoing IP packet's destination IP address is NOT an IP multicast address. If it is, it is sent immediately, bypassing the **ip fltr out hook** function. This hook function is invoked after inserting the IP options from the upper protocol layers, constructing the complete IP header, and locating a route to the destination IP address. The ip fltr out hook function may modify the outgoing IP packet (pkt), but the interface and route have already been assigned and may not be changed. The return value from the ip\_fltr\_out\_hook function indicates whether pkt should be transmitted or dropped. See the Expected Return Values section below. If pkt is not dropped (FIREWALL OK), it's source address is verified to be local and, if pkt is to be

broadcast, the ability to broadcast is confirmed. Thereafter, pkt is enqueued on the interfaces (ifp) output queue. If pkt is dropped (FIREWALL NOTOK), it is not transmitted and EACCES is returned to the process.

The inbound\_fw and outbound\_fw firewall hooks allow kernel extensions to get control of packets at the place where IP receives them. If **inbound fw** is set, **ipintr noqueue**, the IP input routine, calls inbound\_fw and then exits. If not, ipintr\_noqueue calls ipintr\_noqueue\_post\_fw and then exits. If the inbound fw hook routine wishes to pass the packet into IP, it can call ipintr noqueue post fw. inbound\_fw may copy its args parameter by calling inbound\_fw\_save\_args, and may free its copy of its args parameter by calling inbound fw free args.

Similarly, ip\_output calls outbound\_fw if it is set, and calls ip\_output\_post\_fw if not. The outbound\_fw hook can call ip\_output\_post\_fw if it wants to send a packet. outbound\_fw may copy its args parameter by calling outbound\_fw\_save\_args, and later free its copy of its args parameter by calling outbound\_fw\_free\_args.

## Flags

**IP FORWARDING** Indicates that most of the IP headers exist. IP\_RAWOUTPUT Indicates that the raw IP header exists. IP\_MULTICAST\_OPTS Indicates that multicast options are present.

IP ROUTETOIF Contains bypass routing tables.

IP ALLOWBROADCAST Provides capability to send broadcast packets.

IP BROADCASTOPTS Contains broadcast options inside. **IP PMTUOPTS** Provides PMTU discovery options. IP\_GROUP\_ROUTING Contains group routing gidlist.

## **Expected Return Values**

FIREWALL OK Indicates that pkt is acceptable for any of the filtering functions. It will be

delivered, forwarded, or transmitted as appropriate.

FIREWALL\_NOTOK Indicates that pkt should be dropped. It will not be received (ip\_fltr\_in\_hook,

ipsec\_decap\_hook) or transmitted (ip\_fltr\_out\_hook).

FIREWALL\_OK\_NOTSEC Indicates a return value only valid for the <code>ipsec\_decap\_hook</code> function. This

> indicates that pkt is acceptable according to the filtering rules, but is not encapsulated; pkt will be processed by the transport layer rather than processed

as a decapsulated IP packet.

#### **Related Information**

See Network Kernel Services AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# i\_pollsched Kernel Service

# Purpose

Queue a pseudo interrupt to an interrupt handler list.

# **Syntax**

#include <sys/intr.h> int i pollsched (handler, pril) struct intr \*handler; int pril;

#### **Parameters**

handler Pointer to the intr structure for which the interrupt is to be queued.

Processor level to gueue logical interrupt for. pril

## **Description**

The i pollsched service allows device drivers to queue a pseudo interrupt to another interrupt handler. The calling arguements are mutually exclusive. If handler is not NULL then it is used to generate a pril value, via pal i genplvl subroutine. If the handler is NULL then the value in pril represents the processor level of the target interrupt handler.

This service will not queue an interrupt to a funneled, or nonMPSAFE interrupt handler, unless the service is executing on the MPMASTER processor. INTR FAIL will be returned if not executing on MPMASTER processor and the target interrupt handler is not MPSAFE.

This service should only be called on an RSPC based platform (running AIX® 5.1 or earlier). Calling this service on a non-RSPC machine will always result in a failure return code.

### **Execution Environment**

The i\_pollsched kernel service can be called from either the process of interrupt environments.

### **Return Values**

INTR\_SUCC Interrupted was queued.

INTR\_FAIL Interrupt was not queued. This can be returned when the target list was NULL or the service was

called on an invalid platform.

### i reset Kernel Service

# Purpose

Resets a bus interrupt level.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/intr.h>
void i_reset ( handler)
struct intr *handler;
```

#### **Parameter**

handler Specifies the address of an interrupt handler structure passed to the **i\_init** service.

# **Description**

The i reset service resets the bus interrupt specified by the handler parameter. A device interrupt handler calls the i reset service after resetting the interrupt at the device on the bus. See i init kernel service for a brief description of interrupt handlers.

### **Execution Environment**

The i\_reset kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The i reset service has no return values.

### **Related Information**

The i init kernel service.

Understanding Interrupts, I/O Kernel Services, Processing Interrupts in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### i sched Kernel Service

## **Purpose**

Schedules off-level processing.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/intr.h>
void i sched ( handler)
struct intr *handler;
```

#### **Parameter**

handler Specifies the address of the pinned interrupt handler structure.

# **Description**

The i\_sched service allows device drivers to schedule some of their work to be processed at a less-favored interrupt priority. This capability allows interrupt handlers to run as guickly as possible. avoiding interrupt-processing delays and overrun conditions. See the i init kernel service for a brief description of interrupt handlers.

Processing can be scheduled off-level in the following situations:

- The interrupt handler routine for a device driver must perform time-consuming processing.
- This work does not need to be performed immediately.

Attention: The caller cannot alter any fields in the intr structure from the time the i\_sched service is called until the kernel calls the off-level routine. The structure must also stay pinned. Otherwise, the system may crash.

The interrupt handler structure pointed to by the *handler* parameter describes an off-level interrupt handler. The caller of the i sched service must set up all fields in the intr structure. The INIT OFFLn macros in the /usr/include/sys/intr.h file can be used to initialize the handler parameter. The n value represents the priority class that the off-level handler should run at. Currently, classes from 0 to 3 are defined.

Use of the i sched service has two additional restrictions:

First, the i sched service will not re-register an intr structure that is already registered for off-level handling. Since i sched has no return value, the service will simply return normally without registering the specified structure if it was already registered but not yet executed. The kernel removes the intr structure from the registration list immediately prior to calling the off-level handler specified in the structure. It is therefore possible for the off-level handler to use the structure again to register another off-level request.

Care must be taken when scheduling off-level requests from a second-level interrupt handler (SLIH). If the off-level request is already registered but has not yet executed, a second registration will be ignored. If the off-level handler is currently executing, or has already run, a new request will be registered. Users of this service should be aware of these timing considerations and program accordingly.

Second, the kernel uses the flags field in the specified intr structure to determine if this structure is already registered. This field should be initialized once before the first call to the i\_sched service and should remain unmodified for future calls to the i sched service.

Note: Off-level interrupt handler path length should not exceed 5,000 instructions. If it does exceed this number, real-time support is adversely affected.

### **Execution Environment**

The i\_sched kernel service can be called from either the process or interrupt environment.

### Return Values

The i sched service has no return values.

### **Related Information**

The i init kernel service.

Understanding Interrupts, I/O Kernel Services, Processing Interrupts in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## i unmask Kernel Service

# Purpose

Enables a bus interrupt level.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/intr.h>
void i unmask ( handler)
struct intr *handler;
```

#### **Parameter**

handler Specifies the address of the interrupt handler structure that was passed to the i\_init service.

# **Description**

The i unmask service enables the bus interrupt level specified by the handler parameter.

### **Execution Environment**

The i\_unmask kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The i unmask service has no return values.

### **Related Information**

The i\_init kernel service, i\_mask kernel service.

Understanding Interrupts, I/O Kernel Services, Processing Interrupts in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### Idata alloc Kernel Service

## **Purpose**

Allocates a pinned storage element from an Idata pool.

## **Syntax**

#include <sys/ldata.h>

void \* ldata alloc (ldatap)

ldata\_t ldatap;

## **Description**

The **Idata alloc** kernel service allocates a pinned storage element from a **Idata** pool and returns the address of the element. The Idata\_alloc kernel service makes a pinned storage element from the Idata pool available for use by the caller. The sub-pool from which the element is allocated corresponds to the SRAD on which the call was made. If there are no free pinned elements, a new element cannot be allocated and a NULL value is returned.

After it is allocated, the pinned storage element can be freed to the Idata pool through the Idata\_free kernel service.

#### **Parameters**

Idatap

Specifies the handle of the Idata pool.

#### **Execution Environment**

The Idata\_alloc kernel service can be called from the process or interrupt environment.

#### **Return Values**

Returns a pointer to a pinned storage element allocated from an Idata pool or NULL if no element could be allocated.

# Implementation Specifics

The Idata\_alloc kernel service is part of the Base Operating System (BOS) Runtime.

### **Related Information**

The Idata create, Idata grow, Idata free kernel services.

### Idata\_create Kernel Service

## **Purpose**

Creates a SRAD-aware pinned storage element pool (Idata pool) and returns its handle.

## **Syntax**

```
#include <sys/ldata.h>
int ldata_create (size, initcount, maxcount, kkey, ldatap)
size t size;
long initcount;
long maxcount;
kkey t kkey;
ldata_t * ldatap;
```

## Description

The **Idata** create kernel service creates a SRAD-aware pool (**Idata** pool) of pinned storage elements, each of the specified size, and returns a handle to the newly-allocated pool. An Idata pool consists of a number of sub-pools (one per SRAD). Each sub-pool is physically backed with memory local to its corresponding SRAD. The size of each sub-pool is equal to the value of the maxcount parameter multiplied by the value of the size parameter. The parameter (initcount) specifies the number of pinned storage elements in each sub-pool that should be pre-allocated.

The **Idata** pool can be created with a kernel storage protection key by specifying one through the *kkey* parameter. For compatibility with previous releases, a kkey parameter of zero requests no protection. When a protection key is specified, the caller must hold this key when calling any ldata service, including the Idata create kernel service.

After an **Idata** pool is created, its handle can be used to allocate pinned storage elements from the pool through the Idata\_alloc kernel service and free these elements to the pool through the Idata\_free kernel services. Elements are allocated and freed to the sub-pool corresponding to the SRAD on which Idata\_alloc and Idata\_free are called. If a sub-pool is exhausted of its pinned storage elements, it can be grown by calling the **Idata\_grow** kernel service up to *maxcount*.

An Idata pool created through the Idata\_create service can be destroyed by the Idata\_destroy kernel service.

#### **Parameters**

size Specifies the size, in bytes, of each pinned storage element of the **Idata** pool.

Specifies the initial count of pinned storage elements, to be contained within the Idata initcount

pool. Must be a positive integer.

maxcount Specifies the maximum count of pinned storage elements that can be contained with

the **Idata** pool. The value of maxcount must be positive and greater than or equal to

the value of initcount.

Specifies the kernel storage protection key to be applied to the newly created Idata kkey

pool. The value must be a valid kernel key number, or zero to indicate that storage

protection is not requested.

Idatap Specifies an address to be set on successful completion with the handle for the newly

created Idata pool.

#### **Execution Environment**

The Idata\_create kernel service can be called only from the process environment.

### **Return Values**

0 Completed successfully. The handle for Idata storage is

returned in *Idatap*.

**EINVAL** Invalid input parameters given. Invalid initcount, maxcount

or kkey. The Idatap parameter is undefined.

**ENOMEM** Error encountered. Insufficient memory to satisfy request.

The *Idatap* parameter is undefined.

## Implementation Specifics

The Idata\_create kernel service is part of the Base Operating System (BOS) Runtime.

#### **Related Information**

The Idata destroy, Idata grow, Idata alloc, Idata free kernel services.

## Idata\_destroy Kernel Service

## **Purpose**

Destroys an Idata pool created by the Idata\_create kernel service.

## **Syntax**

#include <sys/ldata.h>

void ldata\_destroy (ldatap)

ldata\_t ldatap;

# Description

The **Idata destroy** kernel service destroys an **Idata** pool previously created by an **Idata create** call. This routine assumes that all elements allocated from the pool have been freed back to the pool and there are no longer any active elements in the pool.

The Idata\_destroy call unpins and frees all of the storage associated with the handle.

#### **Parameters**

Idatap Specifies the handle of the Idata pool to be destroyed.

#### **Execution Environment**

The **Idata destroy** kernel service can be called from the process environment only.

#### **Return Values**

None.

# Implementation Specifics

The Idata\_destroy kernel service is part of the Base Operating System (BOS) Runtime.

### **Related Information**

The Idata create, Idata grow, Idata alloc, Idata free kernel services.

## Idata\_free Kernel Service

## **Purpose**

Frees a storage element that is pinned to an **Idata** pool.

## **Syntax**

```
#include <sys/ldata.h>
void ldata_free (ldatap, elementp)
ldata_t ldatap;
void * elementp;
```

## Description

The Idata\_free kernel service frees a pinned storage element that was previously allocated to an Idata pool. The pinned storage element is identified through the *elementp* parameter. The element identified by elementp is freed to the sub-pool corresponding to the SRAD that allocated the element.

#### **Parameters**

Specifies the handle of the Idata pool. Idatap

elementp Specifies the address of the pinned storage element to be freed.

### **Execution Environment**

The Idata\_free kernel service can be called from the process or interrupt environment.

### **Return Values**

None.

# Implementation Specifics

The Idata\_free kernel service is part of Base Operating System (BOS) Runtime.

### **Related Information**

The Idata alloc kernel service.

# Idata\_grow Kernel Service

# **Purpose**

Expands the count of available pinned storage elements contained within an Idata pool.

# **Syntax**

```
#include <sys/ldata.h>
int ldata grow (ldatap, count)
ldata_t ldatap;
long count;
```

# **Description**

The Idata\_grow kernel service increases the number of pinned storage elements contained within a per-SRAD sub-pool associated with the **Idata** handle *Idatap*, by count. If the **Idata\_alloc** call fails because there are no more free pinned storage elements in a sub-pool, use the Idata\_grow kernel service. The Idata grow kernel service pins additional count elements from the sub-pool and makes them available for the Idata\_alloc call. All of the sub-pools associated with the handle are grown. If count elements are not available or there is not enough pinned memory available, the Idata grow kernel service fails.

#### **Parameters**

Idatap Specifies the handle of the Idata pool.

Specifies the additional number of storage elements to be pinned in the sub-pool. The count

count value should be greater than 0 and should not increase the sub-pool size

beyond the value of maxcount specified with the Idata\_create call.

### **Execution Environment**

The Idata\_grow kernel service can be called only from the process environment.

### **Return Values**

Success.

-1 Error encountered. Illegal parameters or insufficient

resources.

## **Implementation Specifics**

The Idata\_grow kernel service is part of the Base Operating System (BOS) Runtime.

### **Related Information**

The Idata create kernel service.

# Idmp\_bufest, Idmp\_timeleft, Idmp\_xmalloc, Idmp\_xmfree, and Idmp\_errstr Kernel Services

# Purpose

Obtains information about the current live dump.

```
#include <sys/livedump.h>
kerrno t ldmp bufest (id, cb, len)
dumpid t id;
ras_block_t cb;
size_t *len;
kerrno_t ldmp_timeleft (id, timeleft)
dumpid t id;
long *timeleft;
kerrno t ldmp xmalloc (id, size, align, p)
dumpid_t id;
size t size;
uint align;
void **p;
```

```
kerrno_t ldmp_xmfree (id, p)
dumpid t id;
void *p;
kerrno t ldmp errstr (id, cb, str)
dumpid t id;
ras block t cb;
char *str;
```

align Specifies the log base 2 of the desired alignment. The maximum allowed alignment is 12, 4096

byte alignment.

cb Specifies the ras\_block\_t for the component.

id Specifies the ID of the dump.

Specifies the estimate of data in bytes that can still be buffered by the specified component in this len

pass.

Specifies the memory block to be allocated or freed. р

Specifies the memory size to be allocated. size

Specifies the error message.

timeleft Specifies the time, in nanoseconds, remaining for this pass. This value only has meaning for a

serialized dump. It can be negative.

## **Description**

The Idmp\_bufest kernel service estimates the number of bytes of dump buffer storage available to this component.

The Idmp\_timeleft kernel service estimates the time, in nanoseconds, remaining in this pass.

The **Idmp xmalloc** kernel service allocates storage from the live dump heap.

The **Idmp\_xmfree** kernel service frees live dump heap storage.

The Idmp\_errstr kernel service records an error to be part of the live dump status reporting. The string is contained in the live dump and reported in the error log entry if there is sufficient space.

Important: An error log entry has a maximum length of 2048 bytes. The error string is limited to 128 bytes, including the trailing NULL, and is truncated if too long. The component's path name is also logged.

**Tip:** The **Idmp** errstr kernel service can be called multiple times to report multiple errors. Components are encouraged to limit the size of error strings due to limited space in the error log entry.

### **Return Values**

Indicates a successful completion.

EINVAL RAS xxx BADARGS Indicates that the arguments for the service are not valid. EFAULT\_RAS\_xxx\_BADARGS Indicates that an address argument is not a valid address.

ENOMEM\_RAS\_LDMP\_XMALLOC Indicates that there is insufficient space in the live dump heap to satisfy

this request.

### **Related Information**

The **livedump** kernel service.

## Idmp\_freeparms Kernel Service

## **Purpose**

Frees any data allocated by the live dump associated with an unused Idmp\_parms\_t data item.

## **Syntax**

```
#include <sys/livedump.h>
kerrno t ldmp freeparms (parms)
ldmp_parms_t *parms;
```

### **Parameters**

parms

Points to an item of **Idmp\_parms\_t** type.

# **Description**

The Idmp\_freeparms kernel service is used in the event that you have partially set up the Idmp\_parms\_t data item, but do not want to take a dump. You can use the Idmp\_freeparms kernel service to clean up any data allocated by the live dump subsystem. However, you can always call the Idmp freeparms kernel service after the livedump kernel service, and the ldmp freeparms kernel service returns normally if there is nothing to free.

### **Execution Environment**

The **Idmp** freeparms kernel service can be called from either the process or interrupt environment.

#### **Return Values**

Indicates a successful completion.

EINVAL\_RAS\_LDMP\_FREEPARMS Indicates that the area is not a valid Idmp\_parms\_t data

**EFAULT RAS LDMP FREEPARMS** Indicates that a memory fault results.

#### **Related Information**

The Idmp\_setupparms and Iivedump kernel services.

# Idmp\_setupparms Kernel Service

# **Purpose**

Sets up the **Idmp parms t** parameter for the **Iivedump** kernel service.

# **Syntax**

```
#include <sys/livedump.h>
kerrno t ldmp setupparms (parms)
ldmp parms t *parms;
```

### **Parameters**

Points to an item of Idmp\_parms\_t type. parms

## **Description**

The Idmp\_setupparms kernel service simplifies the process of setting up a live dump by setting up the Idmp\_parms\_t parameter. It does not allocate any storage.

The **Idmp\_setupparms** kernel service performs the following setup for the **Idmp\_parms\_t** parameter:

**Field** Value

ldp evec evecatcher for ldmp parms

current version ldp\_vers

ldp\_flags

LDPP\_CRITICAL ldp\_prio

ldp\_recov NULL NULL ldp\_func NULL ldp\_namepref ldp\_errcode 0 NULL ldp\_symptom NULL ldp\_title ldp\_rsvd1 NULL

#### **Execution Environment**

The Idmp\_setupparms kernel service can be called from either the process or interrupt environment.

### **Return Values**

Indicates a successful completion. **EFAULT RAS LDMP SETUPPARMS** Indicates that the address is not valid.

### **Related Information**

The livedump kernel service.

### IS64U Kernel Service

## Purpose

Determines if the current user-address space is 64-bit or not.

# **Syntax**

#include <sys/types.h> #include <sys/user.h> int IS64U

# Description

The IS64U kernel service returns 1 if the current user-address space is 64-bit. It returns 0 otherwise.

#### **Execution Environment**

The IS64U kernel service can be called from a process or interrupt handler environment. In either case, it will operate only on the current user-address space.

#### **Return Values**

The current user-address space is 32-bits. 0

The current user-address space is 64-bits.

#### **Related Information**

The as att64 kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## k\_cpuextintr\_ctl Kernel Service

## **Purpose**

1

Performs CPU external interrupt control related operations.

## **Syntax**

#include <sys/intr.h>

kerrno t k cpuextintr ctl (command , cpuset , flags) extintctl t command: rsethandle t cpuset; unit flags;

## Description

This kernel services provides means of enabling, disabling, and querying the external interrupt state on the CPUs described by the CPU resource set. Enabling or disabling an CPU external interrupt could affect the external interrupt delivery to the CPU. Normally, on multiple CPU system, external interrupts can be delivered to any running CPU, and the distribution among the CPUs is determined by a predefined method. Any external interrupt can only be delivered to a CPU if its interrupt priority is more favored than the current external interrupt priority of the CPU. When external interrupts are disabled via this interface, any external interrupt priority less favored than INTMAX will be blocked until interrupts are enabled again. This kernel service is applicable only on selective hardware types.

**Note:** Since this kernel service change the way that interrupts are delivered, system performance may be affected. This service guarantees at least one online CPU will have external interrupts enabled for all device interrupts. Any DLPAR CPU removal can fail if the operation breaks this guarantee. On an I/O bound system, one CPU may not be enough to handle all of the external interrupts received by the partition. Performance may suffer when there are not enough CPUs enabled to handle external interrupts.

#### **Parameters**

command

Specifies the operation to the CPU specified by the CPU resource set. One of the following values defined in <sys/intr.h> can be used:

The following commands are supported:

- · EXTINTDISABLE: Disable external interrupts on the CPUs specified by the CPU resource
- EXTINTENABLE: Enable external interrupts on the CPUs specified by the CPU resource set
- · QUERYEXTINTDISABLE: Return a CPU resource set containing the CPUs that have external interrupts disabled.
- QUERYEXTINTENABLE: Return a CPU resource set containing the CPUs that have externals interrupt enabled.

Reference to a CPU resource set. Upon successful return from this kernel service, the CPUs cpuset

that have the external interrupt control operation done will be set in the CPU resource set.

The CPUs specified by this cpuset parameter are logic CPU ids.

Always set to 0 or EINVAL\_INTR\_DIS\_BAD\_FLAGS will be returned. flags

## Security

The caller must have root authority with CAP\_NUMA\_ATTACH capability or PV\_KER\_CONF privilege in the RBAC environment.

### **Execution Environment**

The **k** cpuextintr ctl kernel service can be called from process environment only.

#### Return Values

Upon successful completion, the k\_cpuextintr\_ctl kernel service returns a 0. If unsuccessful, one of the following kerrno value is returned.

kerrno	Description
EINVAL_EXTINTR_BAD_COMMAND	The command value is not valid.
EINVAL_EXTINTR_BAD_FLAGS	The flags value is unknown.
EINVAL_EXTINTR_BAD_CPUSET	The cpuset references NULL.
EINVAL_EXTINTR _NO_RSET	The <i>cpuset</i> is empty.
ENOTSUP_EXTINTR_CALLER	The kernel service is called from the interrupt environment.
ENOSYS_EXTINTR_PLATFORM	This function is not implemented on the platform.
EPERM_EXTINTR_OPER	The caller does not have enough privilege to perform the requested operation.

Note: A return value of success does not necessarily indicate that external interrupts have been enabled or disabled on all of the specified CPUs. For example, if a CPU is not online, then the enable or disable operation will not be performed on that CPU. The caller should check the returned cpuset to see which CPUs have this operation successfully done. The k\_cpuextintr\_ctl kernel service will not block DR CPU add/remove operation during the whole period of system call.

#### **Related Information**

None

# kcap\_is\_set and kcap\_is\_set\_cr Kernel Service

# **Purpose**

Determines if the given capability is present in an effective capability set.

# **Syntax**

```
kcap_is_set (capability)
cap_value_t capability;
kcap_is_set_cr (capability, cred)
cap value t capability;
struct ucred *cred;
```

#### **Parameters**

Specifies the capability to be examined. Must be one of the capabilities named in the capability

sys/capabilities.h header file.

## **Description**

The kcap is set subroutine determines if the given capability is present in the current process' effective capability set. The kcap is set cr subroutine determines if the given capability is present in the effective capability set of the credentials structure referenced by the cred parameter. The cred parameter must be a valid referenced credentials structure.

#### **Return Values**

The kcap\_is\_set and kcap\_is\_set\_cr subroutines return 1 if the capability is present. Otherwise, they return 0.

#### **Related Information**

Security Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## kcid\_curproc Kernel Service

## **Purpose**

Returns the current workload partition ID associated with the calling process.

## **Syntax**

#include <sys/wparid.h>

cid\_t kcid\_curproc ( )

# **Description**

The **kcid curproc** kernel service returns the workload partition ID associated with the calling process. You can use this service to determine whether the requesting process is operating within a workload partition (WPAR).

### **Execution Environment**

The **kcid curproc** kernel service can be called from the process environment only.

#### **Return Values**

If the kcid\_curproc kernel service is successful, it returns the workload partition ID associated with the calling process. If the calling process is not operating within a WPAR, the ID returned is equivalent to the WPAR GLOBAL definition found in the wparid.h header file.

### **Related Information**

The kwpar\_r2vmap\_pid kernel service, kwpar\_v2rmap\_pid kernel service.

# kcred\_genpagvalue Kernel Service

# **Purpose**

Generates a system-wide unique PAG value for a given PAG type.

## **Syntax**

```
int kcred_genpagvalue(crp, pag_type, pag_value, pag_flags);
cred t
              *crp:
int
             pag type;
uint64_t * pag_value;
int
            pag flags;
```

## **Description**

The kcred genpagvalue kernel service generates a new PAG value for a given PAG type. It is essential that for this function to succeed the PAG type must have been previously registered with the operating system using the kcred setpagname kernel service. The scope of the kcred genpagvalue kernel service is limited to maintaining information about the last generated PAG number and accordingly generating a new number. This service optionally stores the PAG value in the cred structure. It does not monitor the PAG values stored in the **cred** structure by other means.

The caller must convert a PAG name to a PAG type using the kcred\_getpagid kernel service prior to invoking the kcred\_genpagvalue kernel service.

The pag\_flags parameter with the PAG\_SET\_VALUE value set causes the generated value to be atomically stored in the process's credentials.

The PAG value returned is of size 64 bits. The number of significant bits is determined by the requested PAG type. 32-bit PAGs have 32 significant bits. 64-bit PAGs have 62 significant bits.

#### **Parameters**

pag\_type The pag\_type parameter is the ID value associated with a PAG name.

This pointer points to a buffer where the OS will return the newly generated PAG value. pag\_value

pag flags This parameter must be 0 or the value **PAG SET VALUE**.

### **Return Values**

A value of 0 is returned upon successful completion. A negative value is returned if unsuccessful.

#### **Error Codes**

**EINVAL** The PAG value cannot be generated because the named PAG type does not exist as part of

**EPERM** The named PAG type is a 32-bit PAG and the caller does not have the SET\_PROC\_DAC

privilege.

genpagvalue Subroutine in AIX Version 7.1 Technical Reference: Base Operating System and Extensions, Volume 1

# kcred\_getcap Kernel Service

## **Purpose**

Copies a capability vector from a credentials structure.

## **Syntax**

```
#include <sys/capabilities.h>
#include <sys/cred.h>
int kcred_getcap ( crp, cap )
struct ucred * cr;
struct __cap_t * cap;
```

#### **Parameters**

crp Pointer to a credentials structure

cap Capabilities set

## **Description**

The **kcred\_getcap** kernel service copies the capability set from the credentials structure referenced by *crp* into *cap. crp* must be a valid, referenced credentials structure.

### **Execution Environment**

The kcred\_getcap kernel service can be called from the process environment only.

#### **Return Values**

O Success.

-1 An error has occurred.

#### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kcred\_getgroups Kernel Service

# **Purpose**

Copies the concurrent group set from a credentials structure.

# **Syntax**

```
#include <sys/cred.h>
int kcred_getgroups ( crp, ngroups, groups )
struct ucred * cr;
int ngroups;
gid t * groups;
```

#### **Parameters**

*crp* Pointer to a credentials structure

Size of the array of group ID values ngroups

Array of group ID values groups

## **Description**

The kcred\_getgroups kernel service returns up to ngroups concurrent group set members from the credentials structure pointed to by crp. crp must be a valid referenced credentials structure.

#### **Execution Environment**

The kcred getgroups kernel service can be called from the process environment only.

### **Return Values**

The number of concurrent groups copied to groups. >=0

-1 An error has occurred.

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## kcred\_getpag or kcred\_getpag64 Kernel Service

## **Purpose**

Copies a process authentication group (PAG) ID from a credentials structure.

# **Syntax**

```
#include <sys/cred.h>
int kcred getpag ( crp, which, pag )
struct ucred * cr;
int which;
int * pag;
int kcred_getpag64 ( crp, which, pag )
struct ucred * cr;
int which;
uint64 * pag;
```

#### **Parameters**

Pointer to a credentials structure crp

which PAG ID to get

Process authentication group

# **Description**

The kcred\_getpag or kcred\_getpag64 kernel service copies the requested PAG from the credentials structure referenced by crp into pag. The value of which must be a defined PAG ID. The PAG ID for the Distributed Computing Environment (DCE) is 0. crp must be a valid, referenced credentials structure.

#### **Execution Environment**

The kcred\_getpag or kcred\_getpag64 kernel service can be called from the process environment only.

### **Return Values**

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and the errno global variable is set to indicate the error.

#### **Error Codes**

Thekcred\_getpag kernel service fails if the following condition is true:

-EOVERFLOW

PAG value is 64-bit (should be using kcred\_getpag64)

#### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## kcred getpagid Kernel Service

## **Purpose**

Returns the PAG identifier for a PAG name.

## **Syntax**

int kcred getpagid (name) char \*name;

## Description

Given a PAG type name, the kcred getpagid subroutine returns the PAG identifier for that PAG name.

#### **Parameters**

name

A pointer to the name of the PAG type whose integer PAG identifer is to be returned.

#### **Return Values**

A return value greater than or equal to 0 is the PAG identifier. A value less than 0 indicates an error.

#### **Error Codes**

**ENOENT** 

The name parameter doesn't refer to an existing PAG entry.

### **Related Information**

\_pag\_getid System Call" on page 1, "\_\_pag\_getname System Call" on page 1, "\_\_pag\_getvalue System Call" on page 2, "\_\_pag\_setname System Call" on page 3, "\_\_pag\_setvalue System Call" on page 3, "kcred getpagname Kernel Service" on page 249, and "kcred setpagname Kernel Service" on page 254.

# kcred\_getpaginfo Kernel Service

## **Purpose**

Returns a Process Authentication Group (PAG) flags for a given PAG type.

## **Syntax**

```
#include <sys/cred.h>
int kcred getpaginfo ( type, infop, infosz )
int type;
struct paginfo * infop
int infosz;
```

#### **Parameters**

PAG for which the flags are returned infop Pointer to PAG info structure infosz Size of paginfo structure

## **Description**

The kcred getpaginfo kernel service retrieves the flags for the specific PAG type and stores them in a PAG info structure. The value of type must be a defined PAG ID. The PAG ID for the Distributed Computing Environment (DCE) is 0. The infop parameter must be a valid, referenced PAG info structure of the size specified by infosz.

#### **Execution Environment**

The **kcred getpaginfo** kernel service can be called from the process environment only.

### **Return Values**

A value of 0 is returned upon successful completion. Upon failure, a -1 is returned and errno is set to a value that explains the error.

#### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kcred\_getpagname Kernel Service

# **Purpose**

Retrieves the name of a PAG.

# **Syntax**

```
int kcred getpagname (type, buf, size)
int type;
char *buf;
int size;
```

# **Description**

The **kcred getpagname** kernel service retrieves the name of a PAG type given its integer value.

#### **Parameters**

The integer valued identifier representing the PAG type. type

buf A char \* to where the PAG name is copied.

An int that specifies the size of buf in bytes. The size of the buffer must be size

PAG\_NAME\_LENGTH\_MAX+1.

### **Return Values**

If successful, a 0 is returned. If unsuccessful, an error code value less than 0 is returned. The PAG name associated with type is copied into the caller-supplied buffer buf.

#### **Error Codes**

**EINVAL** The value of id is less than 0 or greater than the maximum PAG identifier.

**ENOENT** There is no PAG associated with id.

**ENOSPC** The size parameter is insufficient to hold the PAG name.

#### **Related Information**

"\_\_pag\_getid System Call" on page 1, "\_\_pag\_getname System Call" on page 1, "\_\_pag\_getvalue System Call" on page 2, "\_\_pag\_setname System Call" on page 3, "\_\_pag\_setvalue System Call" on page 3, "kcred\_getpagid Kernel Service" on page 248, and "kcred\_setpagname Kernel Service" on page 254.

# kcred\_getppriv Kernel Service

### **Purpose**

Copies a privilege vector from a credentials structure.

## **Syntax**

```
#include <sys/priv.h>
#include <sys/cred.h>
int kcred getppriv (crp, which, privset)
struct ucred *crp;
int which;
privg_t privset;
```

#### **Parameters**

Points to a credentials structure. crp which Specifies the privilege set to get. privset Specifies the privilege set.

# **Description**

The kcred\_getppriv kernel service returns a single privilege set from the credentials structure referenced by the *crp* parameter. The *which* parameter is one of the values of **PRIV EFFECTIVE**, **PRIV MAXIMUM**, PRIV\_INHERITED, PRIV\_LIMITING, and PRIV\_USED. The corresponding privilege set is copied to the privset parameter. The crp parameter must be a valid, referenced credentials structure.

#### **Execution Environment**

The kcred\_getppriv kernel service can be called from the process environment only.

### **Return Values**

Success.

-1 An error has occurred.

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## kcred\_getpriv Kernel Service

## **Purpose**

Copies a privilege vector from a credentials structure.

## **Syntax**

```
#include <sys/priv.h>
#include <sys/cred.h>
int kcred getpriv ( crp, which, priv )
struct ucred * cr;
int which;
priv_t * priv;
```

### **Parameters**

Pointer to a credentials structure crp

which Privilege set to get Privilege set priv

## **Description**

The kcred\_getpriv kernel service returns a single privilege set from the credentials structure referenced by crp. The which parameter is one of PRIV\_BEQUEATH, PRIV\_EFFECTIVE, PRIV\_INHERITED, or PRIV\_MAXIMUM. The corresponding privilege set will be copied to priv. rp must be a valid, referenced credentials structure.

### **Execution Environment**

The kcred\_getpriv kernel service can be called from the process environment only.

### **Return Values**

Success. to priv. -1 An error has occurred.

#### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kcred\_setcap Kernel Service

# **Purpose**

Copies a capabilities set into a credentials structure.

## **Syntax**

```
#include <sys/capabilities.h>
#include <sys/cred.h>
void kcred setcap ( crp, cap )
struct ucred * cr;
struct __cap_t * cap;
```

#### **Parameters**

Pointer to a credentials structure crp

cap Capabilities set

## **Description**

The kcred\_setcap kernel service initializes the capability set in the credentials structure referenced by crp with cap. rp must be a valid, referenced credentials structure and must not be the current credentials of any process.

### **Execution Environment**

The kcred\_setcap kernel service can be called from the process environment only.

### **Return Values**

The kcred setcap kernel service has no return values.

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kcred\_setgroups Kernel Service

# **Purpose**

Copies a concurrent group set into a credentials structure.

# **Syntax**

```
#include <sys/cred.h>
int kcred setgroups ( crp, ngroups, groups )
struct ucred * cr;
int ngroups;
gid_t * groups;
```

#### **Parameters**

crp ngroups groups

Pointer to a credentials structure Size of the array of group ID values Array of group ID values

## **Description**

The kcred setgroups kernel service copies ngroups concurrent group set members into the credentials structure pointed to by crp. crp must be a valid, referenced credentials structure and must not be the current credentials of any process.

#### **Execution Environment**

The kcred\_setgroups kernel service can be called from the process environment only.

#### **Return Values**

The concurrent group set has been copied successfully.

-1 An error has occurred.

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## kcred\_setpag or kcred\_setpag64 Kernel Service

## **Purpose**

Copies a process authentication group ID into a credentials structure.

# **Syntax**

```
#include <sys/cred.h>
int kcred setpag ( crp, which, pag )
struct ucred * cr;
int which;
int pag;
int kcred setpag64 ( crp, which, pag )
struct ucred * cr;
int which;
uint64 * pag;
```

#### **Parameters**

Pointer to a credentials structure crp

which PAG ID to set

pag Process authentication group

# **Description**

The kcred\_setpag or kcred\_setpag64 kernel service initializes the specified PAG in the credentials structure referenced by crp with pag. The value of which must be a defined PAG ID. The PAG ID for the Distributed Computing Environment (DCE) is 0. Crp must be a valid, referenced credentials structure. crp may be a reference to the current credentials of a process.

#### **Execution Environment**

The kcred\_setpag or kcred\_setpag64 kernel service can be called from the process environment only.

### **Return Values**

0 Success.

-1 An error has occurred.

#### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## kcred\_setpagname Kernel Service

## **Purpose**

Copies a process authentication group ID into a credentials structure.

## **Syntax**

```
int kcred_setpagname (name, flags, func)
char *name;
int flags;
```

## Description

The kcred\_setpagname kernel service registers the name of a PAG and returns the PAG type identifier. If the PAG name has already been registered, the previously returned PAG type identifier is returned if the flags and func parameters match their earlier values.

### **Parameters**

name The name parameter is a 1 to 4 character, NULL-terminated name for the PAG type. Typical values

might include "afs", "dfs", "pki" and "krb5."

The flags parameter indicates if each PAG value is unique (PAG\_UNIQUEVALUE) or multivalued flags

(PAG\_MULTIVALUED). A multivalued PAG type allows multiple calls to the kcred\_setpag kernel

service to be made to store multiple values for a single PAG type.

func The func parameter is a pointer to an allocating and deallocating function. The flag parameter to that

function is either PAGVALUE\_ALLOC or PAGVALUE\_FREE. The value parameter is the actual PAG

value. The func parameter will be invoked by the crfree kernel service with a flag value of PAGVALUE\_FREE on the last free value of a credential. Whenever a credentials structure is

initialized with new PAG values, func will be invoked by that function with a value of

PAGVALUE ALLOC. This parameter may be ignored and an error returned if the value of func is

non-NULL.

#### **Return Values**

A value of 0 or greater is returned upon successful completion. This value is the PAG type identifier which is used with other kernel services, such as the kcred\_getpag and kcred\_setpag subroutines . A negative value is returned if unsuccessful.

### **Error Codes**

**ENOSPC** The PAG table is full.

**EEXISTS** The named PAG type already exists in the table and the flags and func parameters do not match

their earlier values.

**EINVAL** The *flags* parameter is an invalid value.

### **Related Information**

\_pag\_getid System Call" on page 1, "\_\_pag\_getname System Call" on page 1, "\_\_pag\_getvalue System Call" on page 2, "\_\_pag\_setname System Call" on page 3, "\_\_pag\_setvalue System Call" on page 3, "kcred\_getpagid Kernel Service" on page 248, and "kcred\_getpagname Kernel Service" on page 249.

## kcred setppriv Kernel Service

## **Purpose**

Copies a privilege vector into a credentials structure.

## **Syntax**

```
#include <sys/priv.h>
#include <sys/cred.h>
int kcred setppriv (crp, which, privset)
struct ucred *crp;
int which;
privg_t privset;
```

### **Parameters**

crp Points to a credentials structure. Specifies the privilege set to set. which Specifies the privilege set. privset

## **Description**

The kcred\_setppriv kernel service sets one or more single privilege sets in the credentials structure referenced by the crp parameter. The which parameter is the bitwise OR of one or more values of PRIV\_EFFECTIVE, PRIV\_MAXIMUM, PRIV\_INHERITED, PRIV\_LIMITING, and PRIV\_USED. The privset parameter initializes the corresponding privilege sets. The crp parameter must be a valid, referenced credentials structure and cannot be the current credentials of any process.

### **Execution Environment**

The kcred\_setppriv kernel service can be called from the process environment only.

#### **Return Values**

Success.

-1 An error has occurred.

#### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kcred\_setpriv Kernel Service

# **Purpose**

Copies a privilege vector into a credentials structure.

## **Syntax**

```
#include <sys/priv.h>
#include <sys/cred.h>
int kcred setpriv ( crp, which, priv )
struct ucred * cr;
int which;
priv_t * priv;
```

### **Parameters**

crp Pointer to a credentials structure

which Privilege set to set priv Privilege set

## **Description**

The **kcred setpriv** kernel service sets one or more single privilege sets in the credentials structure referenced by crp. The which parameter is one or more bit-wise ored values of PRIV BEQUEATH, PRIV EFFECTIVE, PRIV INHERITED, and PRIV MAXIMUM. The corresponding privilege sets are initialized from priv. crp must be a valid, referenced credentials structure and must not be the current credentials of any process.

#### **Execution Environment**

The **kcred** setpriv kernel service can be called from the process environment only.

### **Return Values**

Success, to priv. -1 An error has occurred.

#### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kern\_soaccept Kernel Service

# **Purpose**

Accepts the first queued connection by assigning it to the new socket.

# **Syntax**

```
#include <svs/kern socket.h>
int kern soaccept( ksocket t so, ksocket t *aso, struct mbuf **name, int nonblock )
```

#### **Parameters**

The socket that was used in solisten().

The new socket for the accepted connection. The caller must pass in the address of a aso

ksocket\_t.

name The struct sockaddr containing the name of the foreign socket that will be filled in once the

routine completes. Caller should pass in the address of struct mbuf \*. Caller needs to free

this mbuf after the function returns.

nonblock

A flag to specify if this call should be non-blocking. The value of 1 is for non-blocking and 0 is for blocking.

## **Description**

The kern\_soaccept kernel service accepts the first queued connection by assigning it to the new socket.

### **Execution Environment**

The **kern\_soaccept** kernel service can be called from the process environment.

## **Examples**

```
struct mbuf *name = NULL;
ksocket t so;
ksocket t aso;
/* Create a socket so, Bind a socket so, Listen on that socket so */
kern socreate(AF INET, &so, SOCK STREAM, IPPROTO TCP);
kern_soaccept(so, &aso, &name, 0);
m_freem(name); /* Caller needs to free the mbuf after kern_soaccept */
```

### **Return Values**

**Upon Success** 

>0 Error

### **Related Information**

kern\_socreate kernel service, kern\_soreceive kernel service, kern\_sosend kernel service

# kern\_sobind Kernel Service

# **Purpose**

Associates the local network address to the socket.

# **Syntax**

```
#include <sys/kern socket.h>
int kern_sobind( ksocket_t so, struct sockaddr *laddr )
```

#### **Parameters**

The socket that was created by the **kern\_socreate()** system call.

laddr Local address to be bound.

# **Description**

The kern sobind kernel service binds a local address to the socket.

#### **Execution Environment**

The **kern\_sobind** kernel service can be called from the process environment.

## **Examples**

```
ksocket_t so;
struct sockaddr_in laddr; /* will be filled in by caller */
kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
kern sobind(so, (struct sockaddr *) &laddr);
```

#### **Return Values**

0 **Upon Success** >0 Error

### **Related Information**

kern socreate kernel service, kern solisten kernel service

### kern\_soclose Kernel Service

## **Purpose**

Aborts any connections and releases the data in the socket.

## **Syntax**

```
#include <sys/kern_socket.h>
int kern soclose( ksocket t so )
```

### **Parameters**

so

The socket on which the close will be issued.

# **Description**

The kern\_soclose kernel service aborts any connection and releases the data in the socket.

### **Execution Environment**

The **kern\_soclose** kernel service can be called from the process environment.

# **Examples**

```
ksocket_t so;
/* Create the socket so */
kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
/* Socket is in use */
kern_soclose(so);
```

### **Return Values**

0 **Upon Success** 

Error >0

### **Related Information**

The kern socreate kernel service.

## kern\_soconnect Kernel Service

## **Purpose**

Establishes a connection to a foreign address.

## **Syntax**

```
#include <sys/kern socket.h>
int kern soconnect( ksocket t so, struct sockaddr *faddr )
```

#### **Parameters**

so The socket that was created by socreate().

faddr Foreign address to connect.

## **Description**

The kern\_soconnect kernel service establishes connection with a foreign address.

### **Execution Environment**

The **kern\_soconnect** kernel service can be called from the process environment.

# **Examples**

```
ksocket t so;
struct sockaddr_in faddr; /* will be filled in by caller */
kern socreate(AF INET, &so, SOCK STREAM, IPPROTO TCP);
kern soconnect(so, (struct sockaddr *) &faddr);
```

### **Return Values**

**Upon Success** >0 Error

#### **Related Information**

The kern\_socreate kernel service, kern\_sosend kernel service, and kern\_soreceive kernel service

# kern\_socreate Kernel Service

# **Purpose**

Used to create a socket of the specified address family and type. If the protocol is left unspecified (zero), then the system selects the protocol based on the address family and type.

## **Syntax**

```
#include <sys/kern_socket.h>
```

int kern\_socreate (int addressfamily, ksocket\_t \*so, int type, int protocol)

#### **Parameters**

addressfamily The address family for the newly created socket. The file <sys/socket.h> contains the

definitions for the family. Currently AIX® supports:

AF INET

Denotes the IPv4 Internet addresses.

AF INET6

Denotes the IPv6 Internet addresses.

so The socket assigned by the create() call. The caller must pass the address of ksocket\_t.

The requested socket type. The file <sys/socket.h> contains the definition for the socket type. type

Currently AIX supports SOCK\_STREAM.

protocol The file <netinet/in.h> contains the definition for the protocol. Currently AIX supports

IPPROTO\_TCP

## **Description**

The **kern\_socreate** kernel service creates a socket based on the address family, type and protocol.

### **Execution Environment**

The **kern socreate** kernel service can be called from the process environment.

# **Examples**

```
ksocket t
               S0;
ksocket t
               so2;
kern socreate(AF INET, &so, SOCK STREAM, IPPROTO TCP);
kern_socreate(AF_INET6, &so2, SOCK_STREAM, 0);
```

### **Return Values**

0 **Upon Success** 

>0 Error

### **Related Information**

The kern\_soclose kernel service, kern\_soconnect kernel service, kern\_soshutdown kernel service.

# kern\_sogetopt Kernel Service

# **Purpose**

Obtains the option associated with the socket, either at the socket level or at the protocol level.

```
#include <sys/kern socket.h>
int kern sogetopt (ksocket t so, int level, int optname, struct mbuf **mp)
```

The socket that will be used to retrieve the option. so

The socket level (e.g. **SOL\_SOCKET**) or protocol level (**IPPROTO\_TCP**) level

The option name to retrieve. Socket options can be found in <sys/socket.h> and TCP options optname

can be found in <netinet/tcp.h> mp

The mbuf that will be returned with the option value. The mp->m\_len will be the size of the mp

value. The caller must pass the address of struct mbuf \*. The caller must free this mbuf after

the function returns.

## **Description**

The kern\_sogetopt kernel service obtains the option associated with the socket, either at the socket level, or at the protocol level.

### **Execution Environment**

The kern\_sogetopt kernel service can be called from the process environment.

## **Examples**

```
ksocket t so;
struct mbuf *sopt = NULL;
int tcp nodelay = -1;
/* Create a socket so */
kern socreate(AF INET, &so, SOCK STREAM, IPPROTO TCP);
sogetopt(so, IPPROTO TCP, TCP NODELAY, &sopt);
tcp nodelay = *mtod(sopt, int *) ? 1 : 0;
If (sopt) m_free(sopt); /* Caller needs to free the mbuf after kern_sogetopt */
```

### **Return Values**

**Upon Success** 

>0 Error

#### **Related Information**

The kern\_socreate kernel service.

# kern\_solisten Kernel Service

# **Purpose**

Prepares to accept incoming connections on the socket.

```
#include <sys/kern socket.h>
int kern_solisten( ksocket_t so, int backlog )
```

so The socket that was created by kern\_socreate() and used in kern\_sobind()

backlog Limit the number of connection requests that can be gueued on this socket. The maximum

value that can be passed to this parameter equals the minimum number of user backlog

number and the network option somaxconn value.

# **Description**

The kern\_solisten kernel service prepares to accept incoming connection on the socket.

### **Execution Environment**

The kern\_solisten kernel service can be called from the process environment.

## **Examples**

```
ksocket_t so;
struct sockaddr in faddr; /* will be filled in by caller */
/* Create a socket so */
kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
/* Bind the socket */
kern sobind(so, (struct sockaddr *) &laddr);
/* Listen */
kern solisten(so, 5);
```

### **Return Values**

0 **Upon Success** 

>0 Error

### **Related Information**

The kern\_socreate kernel service, kern\_soaccept kernel service.

### kern\_soreceive Kernel Service

# **Purpose**

The routine processes one record per call and returns the number of bytes requested.

```
#include <sys/kern_socket.h>
int kern_soreceive( ksocket_t so,
struct mbuf **paddr,
long len,
struct mbuf **mp,
struct mbuf **controlp,
int *flagp )
```

The socket to receive the data. SO

The foreign **socket** address information is returned in this pointer. The caller should pass in paddr

address of struct mbuf \*. The caller must free this mbuf after the function returns.

The length of the data to be received. len

The **mbuf** pointer so that data can be returned in an **mbuf** chain. The caller must pass in the mp

address of struct mbuf \*. The caller must free this mbuf after the function returns.

controlp Pointer to an mbuf containing the control information. The caller must pass in the address of

struct mbuf \*. The caller must free this mbuf after the function returns.

flagp If flagp is not NULL, caller can pass in actual flag. The flags are defined in the <sys/socket.h>

file. The **kern\_soreceive** routine will use flags set in *flagp*. The caller can set the *flagsp* to

MSG\_WAITALL or MSG\_NONBLOCK. On return, it will set flagp to MSG\_TRUNC, MSG\_OOB wherever applicable.

## **Description**

The **kern soreceive** kernel service processes one record per call and returns the number of bytes requested.

#### **Execution Environment**

The **kern\_soreceive** kernel service can be called from the process environment.

# **Examples**

```
ksocket t so;
struct mbuf *data;
int flags = 0;
long len; /* Will be filled in by caller for the amount we are willing to receive */
/* Create and Connect the socket so */
do {
       err = soreceive(so, NULL, len, &data, NULL, &flags);
                               /* process the mbuf data */
     m freem(data); /* Caller needs to free the mbuf after kern sosetopt. */
} while (err == EAGAIN || err == EINTR || err == ERESTART);
If (err) { return err; }
```

### **Return Values**

**Upon Success** Λ >0 Error

### **Related Information**

The kern\_socreate kernel service, kern\_sosend kernel service

## kern\_soreserve Kernel Service

## **Purpose**

The routine enforces the limit for the send and receive buffer space for a socket. It does not actually allocate memory only sets the buffer size.

## **Syntax**

```
#include <sys/kern_socket.h>
int kern_soreserve( ksocket_t so, uint64_t sndcc, uint64_t rcvcc )
```

#### **Parameters**

so The socket that will be used in reserving the space.

sndccSend buffer size in bytes.rcvccReceive buffer size in bytes.

## Description

The **kern\_soreserve** kernel service enforces the limit for the send and receive buffer space for a socket. It does not actually allocate memory. It sets the buffer size.

### **Execution Environment**

The kern\_soreserve kernel service can be called from the process environment.

## **Examples**

```
ksocket_t so;
/*Create the socket so */
kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
kern soreserve(so, sb snd hiwat, sb rcv hiwat);
```

### **Return Values**

0 Upon Success >0 Error

### **Related Information**

The kern socreate kernel service.

## kern\_sosend Kernel Service

# **Purpose**

Pass data and control information to the protocol associated send routines.

```
#include <sys/kern_socket.h>
int kern_sosend( ksocket_t so, struct sockaddr *faddr, struct mbuf *top, struct mbuf *control, int flags )
```

so The socket to send data.

faddr The destination address, only necessary if the socket is not connected.

The **mbuf** chain of data to be sent. Remember that the first **mbuf** must have the packet

header filled out. Set the **top->m\_pkthdr.len** to the total length of the data in the **mbuf** chain and the **m\_flags** to **M\_PKTHDR**. The caller must allocate **mbuf** memory before calling the

routine.

control Pointer to an **mbuf** containing the control information to be sent. The caller must allocate **mbuf** 

memory before calling the function if the caller wants to pass in control information.

flags Flags options for this write call. Caller can set flags to MSG\_NONBLOCK.

## **Description**

The **kern\_sosend** kernel service passes data and control information to the protocol associated send routines.

### **Execution Environment**

The **kern\_sosend** kernel service can be called from process environment.

## **Examples**

```
typedef struct packet
char testcase[512];
char arguments[512];
} packet t;
ksocket_t so;
int flags = 0;
struct mbuf *send mbuf;
struct sockaddr in faddr; /* will be filled in by caller */
char testname[512]; /* Will be filled in by caller */
char arguments[512]; /* Will be filled in by caller */
packet t pkt;
/* Socket created and connection initialized so */
send mbuf = m get(M DONOTWAIT,MT SONAME); /* Caller needs to allocate mbuf memory */
bcopy(testname, pkt.testcase, sizeof(pkt.testcase));
bcopy(arguments, pkt.arguments, sizeof(pkt.arguments));
bcopy(&pkt, mtod(send_mbuf, caddr_t), sizeof(packet_t));
kern sosend(so, (struct sockaddr *)&faddr, send mbuf, 0, MSG NONBLOCK));
```

#### **Return Values**

0 Upon Success

>0 Error

### **Related Information**

The kern\_socreate kernel service, kern\_soreceive kernel service.

# kern\_sosetopt Kernel Service

## **Purpose**

Sets the option associated with the socket, either at the socket level or at the protocol level.

## **Syntax**

```
#include <sys/kern_socket.h>
int sosetopt( ksocket_t so, int level, int optname, struct mbuf *mp )
```

#### **Parameters**

so The socket that will be used to set the option.

level The socket level (e.g. SOL\_SOCKET) or protocol level (IPPROTO\_TCP)

optname The option name to set. Socket options can be found in <sys/socket.h> and the TCP options

can be found in <netinet/tcp.h>.

mp The **mbuf** that contains the option value and will be used to modify the field specified by the

option name. The mp->m\_len should be the size of the value. The caller must allocate mbuf

memory before calling the function.

## **Description**

The **kern\_sosettopt** kernel service sets the option associated with the socket, either at the socket level, or at the protocol level.

### **Execution Environment**

The **kern\_sosetopt** kernel service can be called from the process environment.

# **Examples**

```
ksocket_t so;
struct mbuf *mp = NULL;
struct linger *linger;
/* Create a socket so */
kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
mp = m_get(M_DONOTWAIT, MT_SOOPTS); /* Caller of kern_sosetopt must allocate mbuf memory */
mp->m_len = sizeof(struct linger);
linger = mtod(mp, struct linger *);
linger->l_linger = 5;
kern_sosetopt(so, SOL_SOCKET, SO_LINGER, mp);
```

### **Return Values**

**Upon Success** 

>0 Error

### **Related Information**

The kern socreate kernel service.

## kern soshutdown Kernel Service

## **Purpose**

Closes the read-half, write-half or both read and write of a connection.

## **Syntax**

```
#include <sys/kern socket.h>
int kern soshutdown( ksocket t so, int how )
```

#### **Parameters**

The socket to which the shutdown will be issued. so

how 0 read, 1 write, 2 read and write

# **Description**

The kern\_soshutdown kernel service closes the read-half, write-half or both read and write of a connection.

### **Execution Environment**

The **kern\_soshutdown** kernel service can be called from the process environment.

# **Examples**

```
ksocket t
            S0;
/* Create the socket so */
kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
/* Shutting down both the read/write */
kern_soshutdown(so, 2);
```

### **Return Values**

**Upon Success** 

>0 Error

### **Related Information**

The kern\_socreate kernel service.

# kgethostname Kernel Service

## **Purpose**

Retrieves the name of the current host.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>

int
kgethostname ( name, namelen)
char *name;
int *namelen;
```

#### **Parameters**

name Specifies the address of the buffer in which to place the host name.

namelen Specifies the address of a variable in which the length of the host name will be stored. This parameter

should be set to the size of the buffer before the kgethostname kernel service is called.

## **Description**

The **kgethostname** kernel service returns the standard name of the current host as set by the **sethostname** subroutine. The returned host name is null-terminated unless insufficient space is provided.

### **Execution Environment**

The **kgethostname** kernel service can be called from either the process or interrupt environment.

#### Return Value

0 Indicates successful completion.

### **Related Information**

The sethostname subroutine.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kgetpname Kernel Service

# **Purpose**

Provides the calling process's base program name.

# **Syntax**

```
#include <sys/encap.h>
int kgetpname (char * Buffer, size_t *BufferSize);
```

# **Description**

The **kgetpname** kernel service copies the program name of the calling process into the buffer specified by *Buffer*. Including the null terminator, the service copies no more than the lesser of \**BufferSize*,

MAXCOMLEN, or the actual size of the program name in bytes into the buffer. If Buffer is NULL, or \*BufferSize is 0, no copy is performed. If the full program name is copied into the buffer, the total number of bytes copied is written to \*BufferSize. If kgetpname cannot copy the full program name into the buffer, the size in bytes of the full program name is written to \*BufferSize, and ENAMETOOLONG is returned.

### **Execution Environment**

The **kgetpname** kernel service can only be called from the process environment.

#### **Return Values**

The full program name was successfully written to the buffer.

**ENAMETOOLONG** Only part of the full program name was written to the buffer, and kgetpname stored the

(positive) length in bytes (including the null character) of the full program name into

**EINVAL** Buffer is Null, BufferSize is NULL, or \*BufferSize is 0.

**ENOTSUP** The kgetpname kernel service was called from inside an interrupt context.

## kgetrlimit64 Kernel Service

## **Purpose**

Controls maximum system resource consumption.

## Library

Standard C Library (libc.a)

## **Syntax**

#include <sys/time.h> #include <sys/resource.h>

void kgetrlimit64 (Resource1, RLP) int Resource1; struct rlimit64 \*RLP;

Resource1

The Resource1 parameter can be one of the following values:

#### **RLIMIT AS**

The maximum size of a process's total available memory, in bytes. This limit is not enforced.

#### RLIMIT\_CORE

The largest size, in bytes, of a core file that can be created. This limit is enforced by the kernel. If the value of the RLIMIT\_FSIZE limit is less than the value of the RLIMIT\_CORE limit, the system uses the RLIMIT\_FSIZE limit value as the soft limit.

#### RLIMIT\_CPU

The maximum amount of central processing unit (CPU) time, in seconds, to be used by each process. If a process exceeds its soft CPU limit, the kernel sends a SIGXCPU signal to the process. After the hard limit is reached, the process is killed with SIGXCPU, even if it handles, blocks, or ignores that signal.

#### RLIMIT\_DATA

The maximum size, in bytes, of the data region for a process. This limit defines how far a program can extend its break value with the sbrk subroutine. This limit is enforced by the kernel.

#### **RLIMIT FSIZE**

The largest size, in bytes, of any single file that can be created. When a process attempts to write, truncate, or clear beyond its soft RLIMIT\_FSIZE limit, the operation fails with the errno variable set to EFBIG. If the environment variable XPG SUS ENV=ON is set in the user's environment before the process is issued, then the SIGXFSZ signal is also generated.

#### RLIMIT NOFILE

This is a number one greater than the maximum value that the system can assign to a newly-created descriptor.

#### **RLIMIT STACK**

The maximum size, in bytes, of the stack region for a process. This limit defines how far a program stack region can be extended. The system automatically performs stack extension. This limit is enforced by the kernel. When the stack limit is reached, the process receives a SIGSEGV signal. If this signal is not caught by a handler using the signal stack, the signal ends the process.

#### RLIMIT\_RSS

The maximum size, in bytes, to which the resident set size of a process can grow. This limit is not enforced by the kernel. A process might exceed its soft limit size without being

RLP

Points to the rlimit64 structure where the requested limits are returned by the kgetrlimit64 kernel service.

# **Description**

The kgetrlimit64 kernel service returns the values of limits on system resources used by the current process and its children processes.

Note: The initial values returned by the kgetrlimit64 kernel service are the ulimit values in effect when the process was started. For maxdata programs the initial soft limit for data is set to the lower of data ulimit value or a value corresponding to the number of data segments reserved for data segments.

The rlimit64 structure specifies the hard and soft limits for a resource, as defined in the sys/resource.h file. The RLIM64\_INFINITY value defines an infinite value for a limit.

## **Execution Environment**

The **kgetrlimit64** kernel service can be called from either the process or interrupt environment.

### **Return Values**

The kgetrlimit64 kernel service has no return values.

### **Related Information**

The getrlimit64 subroutine in AIX Version 7.1 Technical Reference: Base Operating System and Extensions, Volume 1.

# kgetsystemcfg Kernel Service

## **Purpose**

Displays the system configuration information.

## **Syntax**

#include <systemcfg.h> uint64 t kgetsystemcfg ( int name)

## Description

Displays the system configuration information.

### **Parameters**

name

Specifies the system variable setting to be returned. Valid values for the name parameter are defined in the systemcfg.h file.

## **Return Values**

If the value specified by the *name* parameter is system-defined, the **kgetsystemcfg** kernel service returns the data that is associated with the structure member represented by the input parameter. Otherwise, the kgetsystemcfg kernel service will return UINT64\_MAX, and the errno will be set.

### **Error Codes**

The kgetsystemcfg subroutine will fail if:

**EINVAL** 

The value of the *name* parameter is invalid.

### **Related Information**

The **getsystemcfg** subroutine.

# kgettickd Kernel Service

# **Purpose**

Retrieves the current status of the systemwide time-of-day timer-adjustment values.

## **Syntax**

```
#include <sys/types.h>
int kgettickd (timed, tickd, time_adjusted)
int *timed;
int *tickd;
int *time_adjusted;
```

#### **Parameters**

timed Specifies the current amount of time adjustment in microseconds remaining to be applied to

the systemwide timer.

tickd Specifies the time-adjustment rate in microseconds.

time\_adjusted Indicates if the systemwide timer has been adjusted. A value of True indicates that the timer

has been adjusted by a call to the **adjtime** or **settimer** subroutine. A value of False indicates that it has not. The use of the **ksettimer** kernel service has no effect on this flag.

This flag can be changed by the **ksettickd** kernel service.

## **Description**

The **kgettickd** kernel service provides kernel extensions with the capability to determine if the **adjtime** or **settimer** subroutine has adjusted or changed the systemwide timer.

The **kgettickd** kernel service is typically used only by kernel extensions providing time synchronization functions. This includes coordinated network time (which is the periodic synchronization of all system clocks to a common time by a time server or set of time servers on a network), where use of the **adjtime** subroutine is insufficient.

### **Execution Environment**

The kgettickd kernel service can be called from either the process or interrupt environment.

### **Return Values**

The **kgettickd** service always returns a value of 0.

#### Related Information

The ksettimer kernel service.

The adjtime subroutine, settimer subroutine.

Timer and Time-of-Day Kernel Services and Using Fine Granularity Timer Services and Structures in AIX<sup>®</sup> Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kkey\_assign\_private Kernel Service

# **Purpose**

Requests a private kernel-key assignment.

# **Syntax**

```
#include <sys/types.h>
#include <sys/skeys.h>
#include <sys/kerrno.h>

kerrno_t kkey_assign_private (id, instance, flags, kkey)
char *id;
```

272 AIX® Version 7.1 Technical Reference: Kernel and Subsystems, Volume 1

long instance; unsigned long flags; kkey t \*kkey;

### **Parameters**

id Specifies a null-terminated string. The kkey\_assign\_private kernel service uses the string value to

assign a private key. This normally contains a load module name associated with the calling kernel

subsystem, but you can specify any unique string.

Specifies a unique number for each private key requested by a subsystem. This must be an integer instance

value starting from 0 and increases with each kernel-key requested.

flags You must specify this parameter to zero.

Contains the returned assigned kernel key. The valid pointer must be a 4-byte aligned address kkey

(kkey t's natural alignment).

## **Description**

The kkey\_assign\_private kernel service assigns a private kernel key to the caller. Private kernel keys are used to limit data accessibility by external kernel code. The kkey\_assign\_private kernel service distributes requests for private kernel keys among a predetermined range (from KKEY\_PRIVATE1 to KKEY\_PRIVATE32). The intention is to perform a uniform distribution on behalf of requests by multiple kernel subsystems. The assignment is made based on the id and instance parameters and might return the same private key to multiple callers. It might also return the same private key when the instance number is different.

The **kkey assign private** kernel service does not perform a resource allocation. It only provides a recommended kernel key to use for data protection.

### **Execution Environment**

The kkey\_assign\_private kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful completion.

EINVAL KKEY ASSIGN PRIVATE Indicates that the parameter or execution environment is not valid.

# kkeyset\_add\_key Kernel Service

# Purpose

Adds a kernel key to a kernel keyset.

# **Syntax**

```
#include <sys/kerrno.h>
#include <sys/skeys.h>
```

```
kerrno_t kkeyset_add_key (set, key, flags)
kkeyset_t set;
kkey t key;
unsigned long flags;
```

## **Parameters**

set

Specifies the kernel keyset to which the **kkeyset add key** kernel service will add a key.

key Specifies the kernel key to add.

You can specify the flags parameter to one of the following values: flags

Specifies that the read access for the key is to be added.

**KA WRITE** 

Specifies that the write access for the key is to be added.

KA RW

Specifies that both the read access and the write access are to be added. This is equivalent to the value of KA\_READ | KA\_WRITE.

## **Description**

The kkeyset\_add\_key kernel service adds a single kernel key specified by the key parameter to the kernel keyset specified by the set parameter. You must specify the flags parameter to control the read or write authority.

### **Execution Environment**

The kkeyset\_add\_key kernel service can be called from the process environment only.

## **Return Values**

Indicates a successful completion.

EINVAL\_KKEYSET\_ADD\_KEY Indicates that the parameter or execution environment is not valid.

# kkeyset add set Kernel Service

## **Purpose**

Adds members of one kernel keyset to an existing kernel keyset.

# **Syntax**

```
#include <sys/kerrno.h>
#include <sys/skeys.h>
kerrno t kkeyset add set (set, addset)
kkeyset_t set;
kkeyset t addset;
```

### **Parameters**

set Specifies an existing kernel keyset. This set contains the resulting union on completion.

addset Specifies the kernel keyset to add.

# **Description**

The kkeyset\_add\_set kernel service adds a kernel keyset specified by the addset parameter to the kernel keyset specified by the set parameter.

#### **Execution Environment**

The **kkeyset add set** kernel service can be called from the process environment only.

## **Return Values**

Indicates a successful completion.

EINVAL\_KKEYSET\_ADD\_SET Indicates that the parameter or execution environment is not valid.

## kkeyset create Kernel Service

## **Purpose**

Creates and initializes a kernel keyset.

## **Syntax**

#include <sys/kerrno.h> #include <sys/skeys.h>

kerrno t kkeyset create (set) kkeyset\_t \*set;

### **Parameters**

set

Contains the returned newly-created keyset.

## **Description**

The kkeyset\_create kernel service creates a new (empty) kernel keyset. You can add or remove the access to an individual or groups of kernel keys using the kkeyset\_add\_key, kkeyset\_remove\_key, kkeyset add set, and kkeyset remove set kernel services.

Important: The kkeyset\_create kernel service allocates hidden kernel resources. You must release these resources using the **kkeyset delete** kernel service when the kernel keyset is no longer in use. When creating a new set, the caller of the kkeyset\_create kernel service must initialize the storage that will contain the returned kernel keyset (\*set) to the value of KKEYSET\_INVALID.

### **Execution Environment**

The kkeyset\_create kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful completion.

ENOMEM\_KKEYSET\_CREATE Indicates that the available memory is not sufficient to satisfy the request. EINVAL\_KKEYSET\_CREATE Indicates that the parameter or execution environment is not valid.

### **Related Information**

The kkeyset add key kernel service, kkeyset remove key kernel service, kkeyset add set kernel service, kkeyset remove set kernel service, kkeyset delete kernel service.

# kkeyset\_delete Kernel Service

# **Purpose**

Deletes a kernel keyset.

## **Syntax**

```
#include <sys/kerrno.h>
#include <sys/skeys.h>
kerrno_t kkeyset_delete (set)
kkeyset t set;
```

### **Parameters**

Specifies the keyset to be destroyed. set

# **Description**

The kkeyset\_delete kernel service destroys a kernel keyset. The kernel service releases the hidden resources associated with this keyset.

### **Execution Environment**

The **kkeyset** delete kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful completion.

**EINVAL KKEYSET DELETE** Indicates that the parameter or execution environment is not valid.

# kkeyset\_remove\_key Kernel Service

## **Purpose**

Removes a kernel key from a kernel keyset.

# **Syntax**

```
#include <sys/kerrno.h>
#include <sys/skeys.h>
kerrno t kkeyset remove key (set, key, flags)
kkeyset t set;
kkey_t key;
unsigned long flags;
```

### **Parameters**

set Specifies the kernel keyset from which the kkeyset\_remove\_key kernel service will remove a key.

key Specifies the kernel key to remove.

You can specify the flags parameter to one of the following values: flags

KA\_READ

Specifies that the read access for the key is to be removed.

KA\_WRITE

Specifies that the write access for the key is to be removed.

KA RW

Specifies that both the read access and the write access are to be removed. This is equivalent to the value of KA\_READ | KA\_WRITE.

## **Description**

The kkeyset\_remove\_key kernel service removes a single kernel key specified by the key parameter from the kernel keyset specified by the set parameter. You must specify the flags parameter to control the read or write authority.

### **Execution Environment**

The kkeyset\_remove\_key kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful completion.

EINVAL\_KKEYSET\_REMOVE\_KEY Indicates that the parameter or execution environment is not valid.

## kkeyset\_remove\_set Kernel Service

## **Purpose**

Removes members of one kernel keyset from an existing kernel keyset.

## **Syntax**

```
#include <sys/kerrno.h>
#include <sys/skeys.h>
kerrno_t kkeyset_remove_set (set, removeset)
kkeyset_t set;
kkeyset t removeset;
```

### **Parameters**

Specifies the kernel keyset from which the kkeyset\_remove\_set kernel service will remove a set

Specifies the kernel keyset to remove. removeset

# **Description**

The kkeyset\_remove\_set kernel service removes a kernel keyset specified by the removeset parameter from the kernel keyset specified by the set parameter.

### **Execution Environment**

The kkeyset\_remove\_set kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful completion.

EINVAL\_KKEYSET\_REMOVE\_SET Indicates that the parameter or execution environment is not valid.

# kkeyset\_to\_hkeyset Kernel Service

# **Purpose**

Computes the hardware keyset associated with a kernel keyset.

## **Syntax**

```
#include <sys/kerrno.h>
#include <sys/skeys.h>
kerrno_t kkeyset_to_hkeyset (kkeyset, hkeyset)
kkeyset t kkeyset;
hkeyset t *hkeyset;
```

### **Parameters**

kkeyset Specifies the input kernel keyset to be mapped.

hkeyset Specifies the hardware keyset that is mapped to. The valid pointer must be an 8-byte aligned

address.

## Description

The **kkeyset to hkeyset** kernel service maps a kernel keyset to its associated hardware keyset.

### **Execution Environment**

The kkeyset\_to\_hkeyset kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful completion.

EINVAL\_KKEYSET\_TO\_HKEYSET Indicates that the parameter or execution environment is not valid.

# klpar\_get\_info Kernel Service

# **Purpose**

Retrieves the calling partition's characteristics.

# **Syntax**

```
#include <sys/dr.h>
int klpar_get_info (command, lparinfo, bufsize)
int command;
void *lparinfo;
size_t bufsize;
```

### **Parameters**

command Specifies whether the user wants format1, format2, or processor module details.

Iparinfo Pointer to the user-allocated buffer that is passed in.

bufsize Size of the buffer that is passed in.

# **Description**

The **klpar\_get\_info** kernel service retrieves LPAR and Micro-Partitioning<sup>™</sup> attributes of both low-frequency use and high-frequency use and also retrieves processor module information. Because the low-frequency attributes, as defined in the **lpar\_info\_format1\_t** structure, are static in nature, a reboot is required to effect any change. The high-frequncy attributes, as defined in the Ipar\_info\_format2\_t structure, can be changed dynamically while the partition is running. The signature of this kernel service, its parameter types, and the order of the member fields in both the <a href="Ipar\_info\_format1\_t">Ipar\_info\_format2\_t</a> and <a href="Ipar\_info\_format2\_t">Ipar\_info\_format1\_t</a> and <a href="Ipar\_info\_format2\_t">Ipar\_info\_format2\_t</a>

structures are specific to the AIX® platform. If you requests processor module information, the kernel service provides this information as an array of **proc module info t** structures. To obtain this information, the caller must provide a buffer of the exact length to accommodate one proc\_module\_info\_t structure for each module type. You can obtain the module count using the NUM\_PROC\_MODULE\_TYPES command. The module count is in the form of a uint64 t type. Processor module information is reported for the entire system. This information is available on POWER6® and later systems.

To see the complete structures of **lpar info format1 t**, **lpar info format2 t**, and **proc module info t**, refer to the dr.h header file.

### **Return Values**

Upon success, the klpar\_get\_info kernel service returns a value of 0. Upon failure, the klpar\_get\_info kernel service returns an error code.

### **Error Codes**

**EINVAL** Invalid input parameter.

**ENOSYS** The hardware or the firmware level does not support this operation.

**ENOTSUP** The platform does not support this operation.

## **Related Information**

The **lpar\_get\_info** subroutine.

# kmod entrypt Kernel Service

## **Purpose**

Returns a function pointer to a kernel module's entry point.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/ldr.h>
void (*(kmod entrypt ( kmid, flags)))( )
mid t kmid;
uint flags;
```

#### **Parameters**

kmid Specifies the kernel module ID of the object file for which the entry point is requested. This parameter is the kernel module ID returned by the kmod\_load kernel service.

Flag specifying entry point options. The following flag is defined: flags

> Returns a function pointer to the specified module's entry point as specified in the module header. n

# **Description**

The **kmod** entrypt kernel service obtains a function pointer to a specified module's entry point. This function pointer is typically used to invoke a routine in the module for initializing or terminating its functions. Initialization and termination occurs after loading and before unloading. The module for which the entry point is requested is specified by the kernel module ID represented by the kmid parameter.

## **Execution Environment**

The **kmod\_entrypt** kernel service can be called from the process environment only.

### **Return Values**

A nonnull function pointer indicates a successful completion. This function pointer contains the module's entry point. A null function pointer indicates an error.

### **Related Information**

The kmod load kernel service.

Kernel Extension and Device Driver Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## kmod load Kernel Service

## **Purpose**

Loads an object file into the kernel or gueries for an object file already loaded.

# **Syntax**

```
#include <sys/ldr.h>
#include <sys/types.h>
#include <sys/errno.h>
int kmod load (pathp,
flags, libpathp, kmidp)
caddr_t pathp;
uint flags;
caddr t
libpathp;
mid_t * kmidp;
```

### **Parameters**

pathp

Points to a character string containing the path-name of the object file to load or query.

flags

Specifies a set of loader flags describing which loader options to invoke. The following flags are defined:

#### LD\_USRPATH

The character strings pointed to by the *pathp* and *libpathp* parameters are in user address space. If the **LD\_USRPATH** flag is not set, the character strings are assumed to be in kernel, or system, space.

#### LD\_KERNELEX

Puts this object file's exported symbols into the /usr/lib/boot/unix name space. Additional object files loaded due to symbol resolution for the specified file do not have their exported symbols placed in kernel name space.

### LD\_SINGLELOAD

When this flag is set, the object file specified by the *pathp* parameter is loaded into the kernel only if an object file with the same path-name has not already been loaded. If an object file with the same path-name has already been loaded, its module ID is returned (using the *kmidp* parameter) and its load count incremented. If the object file is not yet loaded, this service performs the load as if the flag were not set.

This option is useful in supporting global kernel routines where only one copy of the routine and its data can be present. Typically, routines that export symbols to be added to kernel name space are of this type.

**Note:** A path-name comparison is done to determine whether the same object file has already been loaded. This service will erroneously load a new copy of the object file into the kernel if the path-name to the object file is expressed differently than it was on a previous load request.

If neither this flag nor the **LD\_QUERY** flag is set, this service loads a new copy of the object file into the kernel. This occurs even if other copies of the object file have previously been loaded.

#### LD\_QUERY

This flag specifies that a query operation will determine if the object file specified by the *pathp* parameter is loaded. If not loaded, a kernel module ID of 0 is returned using the *kmidp* parameter. Otherwise, the kernel module ID assigned to the object file is returned.

If multiple instances of this file have been loaded into the kernel, the kernel module ID of the most recently loaded object file is returned.

The *libpathp* parameter is not used for this option.

**Note:** A path-name comparison is done to determine whether the same object file has been loaded. This service will erroneously return a not loaded condition if the path-name to the object file is expressed differently than it was on a previous load request.

If this flag is set, no object file is loaded and the **LD\_SINGLELOAD** and **LD\_KERNELEX** flags are ignored, if set.

libpathp

Points to a character string containing the search path to use for finding object files required to complete symbol resolution for this load. If the parameter is null, the search path is set from the specification in the object file header for the object file specified by the *pathp* parameter.

kmidp

Points to an area where the kernel module ID associated with this load of the specified module is to be returned. The data in this area is not valid if the **kmod\_load** service returns a nonzero return code.

# **Description**

The **kmod\_load** kernel service loads into the kernel a kernel extension object file specified by the *pathp* parameter. This service returns a kernel module ID for that instance of the module.

You can specify flags to request a single load, which ensures that only one copy of the object file is loaded into the kernel. An additional option is simply to query for a given object file (specified by path-name). This allows the user to determine if a module is already loaded and then access its assigned kernel module ID.

The kmod load service also provides load-time symbol resolution of the loaded module's imported symbols. The **kmod load** service loads additional kernel object modules if required for symbol resolution.

## **Loader Symbol Binding Support**

Symbols imported from the kernel name space are resolved with symbols that exist in the kernel name space at the time of the load. (Symbols are imported from the kernel name space by specifying the #!/unix character string as the first field in an import list at link-edit time.)

Kernel modules can also import symbols from other kernel object modules. These other kernel object modules are loaded along with the specified object module if they are needed to resolve the imported symbols.

Any symbols exported by the specified kernel object module are added to the kernel name space if the flags parameter has the LD\_KERNELEX flag set. This makes the symbols available to other subsequently loaded kernel object modules. Kernel object modules loaded on behalf of the specified kernel object module (to resolve imported symbols) do not have their exported symbols added to the kernel name space.

Kernel export symbols specified (at link-edit time) with the SYSCALL keyword in the primary module's export list are added to the system call table. These kernel export symbols are available to application programs as system calls.

## Finding Shared Object Modules for Resolving Symbol References

The search path search string is taken from the module header of the object module specified by the pathp parameter if the libpathp parameter is null. The module header of the object module specified by the pathp parameter is used.

If the module header contains an unqualified base file name for the symbol (no / [slash] characters in the name), a search string is used to find the location of the shared object module required to resolve the import. This search string can be taken from one of two places. If the libpathp parameter on the call to the kmod\_load service is not null, then it points to a character string specifying the search path to be used. However, if the *libpathp* parameter is null, then the search path is to be taken from the module header for the object module specified by the pathp parameter.

The search path specification found in object modules loaded to resolve imported symbols is not used. The kernel loader service does not support deferred symbol resolution. The load of the kernel module is terminated with an error if any imported symbols cannot be resolved.

### **Execution Environment**

The **kmod\_load** kernel service can be called from the process environment only.

#### Return Values

If the object file is loaded without error, the module ID is returned in the location pointed to by the kmidp parameter and the return code is set to 0.

### **Error Codes**

If an error results, the module is not loaded, and no kernel module ID is returned. The return code is set to one of the following return values:

Return Value Description

**EACCES** Indicates that an object module to be loaded is not an ordinary file or that the mode of the

object module file denies read-only access.

EACCES Search permission is denied on a component of the path prefix. Return Value Description

**EFAULT** Indicates that the calling process does not have sufficient authority to access the data area

described by the pathp or libpathp parameters when the LD\_USRPATH flag is set. This error

code is also returned if an I/O error occurs when accessing data in this area.

**ENOEXEC** Indicates that the program file has the appropriate access permission, but has an XCOFF

indicator that is not valid in its header. The **kmod\_load** kernel service supports loading of XCOFF (Extended Common Object File Format) object files only. This error code is also

returned if the loader is unable to resolve an imported symbol.

**EINVAL** Indicates that the program file has a valid XCOFF indicator in its header, but the header is

either damaged or incorrect for the machine on which the file is to be loaded.

**ENOMEM** Indicates that the load requires more kernel memory than allowed by the system-imposed

maximum.

**ETXTBSY** Indicates that the object file is currently open for writing by some process.

**ENOTDIR** Indicates that a component of the path prefix is not a directory. **ENOENT** Indicates that no such file or directory exists or the path-name is null.

**ESTALE** Indicates that the caller's root or current directory is located in a virtual file system that has

been unmounted.

**ELOOP** Indicates that too many symbolic links were encountered in translating the *path* or *libpathp* 

parameter.

**ENAMETOOLONG** Indicates that a component of a path-name exceeded 255 characters, or an entire path-name

exceeded 1023 characters.

**EIO** Indicates that an I/O error occurred during the operation.

## **Related Information**

The kmod unload and kmod util kernel services.

Kernel Extension and Device Driver Management Kernel Services in *AIX® Version 7.1 Kernel Extensions* and Device Support Programming Concepts.

## kmod\_unload Kernel Service

# **Purpose**

Unloads a kernel object file.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/ldr.h>

int kmod_unload ( kmid
, flags)
mid_t kmid;
uint flags;
```

### **Parameters**

kmid Specifies the kernel module ID of the object file to be unloaded. This kernel module ID is returned when using the kmod\_load kernel service.

flags Flags specifying unload options. The following flag is defined:

**0** Unloads the object module specified by its *kmid* parameter and any object modules that were loaded as a result of loading the specified object file if this file is not still in use.

## **Description**

The **kmod unload** kernel service unloads a previously loaded kernel extension object file. The object to be unloaded is specified by the kmid parameter. Upon successful completion, the following objects are unloaded or marked unload pending:

- · The specified object file
- · Any imported kernel object modules that were loaded as a result of the loading of the specified module

Users of these exports or system calls are modules bound to this module's exported symbols. If there are no users of any of the module's kernel exports or system calls, the module is immediately unloaded. If there are users of this module, the module is not unloaded but marked unload pending.

Marking a module *unload pending* removes the module's exported symbols from the kernel name space. Any system calls exported by this module are also removed. This prohibits new users of these symbols. The module is unloaded only when all current users have been unloaded.

If the unload is successfully completed or marked pending, a value of 0 is returned. When an error occurs, the specified module and any imported modules are not unloaded. A nonzero return value indicates the error.

## **Execution Environment**

The **kmod** unload kernel service can be called from the process environment only.

### **Return Values**

Indicates successful completion.

**EINVAL** Indicates that the kmid parameter, which specifies the kernel module, is not valid or does not correspond

to a currently loaded module.

**EBUSY** The *kmid* parameter specifies a kernel extension that is still intercepting system calls.

### **Related Information**

The kmod\_load and kmod\_util kernel services.

Kernel Extension and Device Driver Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kmod util Kernel Service

# **Purpose**

Registers routines to be called before and after specified system calls are invoked.

# **Syntax**

```
#include <sys/sysconfig.h>
int kmod_util ( flags, buffer, blen)
int flags;
void * buffer;
long blen;
```

## **Parameters**

flags

Specifies the operation. Valid values are KU\_INTERCEPT, KU\_INTERCEPT\_STOP, and KU INTERCEPT CANCEL.

buffer

Points to a buffer containing a system call interception header and an array of system call interception

Specifies the length of the buffer. blen

# **Description**

The kmod\_util kernel service allows system calls to be intercepted. Routines called pre-sc functions are specified to be called before the intercepted system call. Routines called **post-sc** functions are specified to be called after the intercepted system call. In addition, a pre-sc function is allowed to abort the system call, providing its own return value and preventing subsequent pre-sc functions and the system call itself from being called. Similarly, each post-sc function may examine and alter the return value. If a system call does not return (e.g., thread terminate), post-sc functions are not called.

For each intercepted system call, either a pre-sc function, a post-sc function, or both, must be specified. If a pre-sc function and post-sc function are registered for the same system call in the same kmod util invocation, they are considered paired. All pre-sc and post-sc functions specified in a kmod\_util call must be defined in the same kernel extension as the caller of the kmod util kernel service. Other kernel extensions, however, can intercept the same system calls. The most recently registered pre-sc function is called first, and its paired **post-sc** function is called last.

The interception of a system call is implemented so that all calls to the system call are intercepted, even for existing processes.

It may be necessary to prevent the interception of certain system calls to avoid destabilizing the system. A future version or release of the kmod util kernel service may prevent the interception of additional system calls, and such a change will not be considered a violation of binary compatibility.

```
The prototype of a pre-sc function is
```

```
int pre sc(uintptr t *rc, void *parms, uintptr t cookie, void *buffer);
```

where parms is a pointer to the parameters of the system call, cookie is an opaque value specified by the caller of **kmod util**, buffer is a scratch 128-byte buffer for use by the **pre-sc** function and its paired post-sc function.

If the pre-sc function returns non-zero, the system call is aborted. The rc parameter is the address where an alternate return value can be specified. Subsequent pre sc functions are not called, nor is the system call. For pre-sc functions already called, their paired post-sc functions are called.

The prototype of a post-sc function is

```
void post sc(uintptr t *rc, void *parms, uintptr t cookie,
   void *buffer);
```

The parameters of the post-sc function are the same as those of the pre-sc function. In particular, the buffer parameter is the same buffer that was passed to the paired pre-sc function. The return value can be modified by a **post-sc** function.

For calls to the **kmod\_util** kernel service, the buffer contains a header and an array of elements about system calls to be intercepted. The layout of these structures is defined in <sys/sysconfig.h>.

An array element is ignored if the KU IGNORE flag is set in the kue iflag field. Otherwise, each array element in the input buffer is validated, and if any errors are found, the entire call fails without any partial execution.

#### **Intercepting System Calls**

Calls to **kmod\_util()** with the **KU\_INTERCEPT** flag initiate system call interception.

### Stopping System Call Interception

Calls to kmod\_util() with the KU\_INTERCEPT\_STOP flag suspend the interception of the specified system calls. If a pre-sc function has already been called for a specified system call, its paired post-sc function will still be called, but future calls to the system call will not invoke either the pre-sc or post-sc function. It is not valid to stop interception of a system call that was not originally intercepted by the calling kernel extension.

If the interception of a system call has been suspended, it may be resumed by calling the kmod\_util() function with the KU\_INTERCEPT flag, as long as the same values are specified, such as the **pre-sc** and **post-sc** functions.

#### Cancelling System Call Interception

System call interception can be cancelled by specifying the KU INTERCEPT CANCEL flag. When interception is cancelled, the post-sc function is not called even if its paired pre-sc function was called. It is not valid to cancel interception of a system call that was not originally intercepted by the calling kernel extension, but interception can be cancelled without first stopping interception.

Once interception of a system call has been cancelled, it can be intercepted anew by calling the kmod util() function with the KU INTERCEPT flag. Different pre-sc and pre-sc functions can be specified in this case.

## **Return Values**

If the specified operations can be enacted for all specified system calls, 0 is returned. Otherwise, a non-zero value is returned and no change in the state of system call interception occurs. If an error occurs because of a validation error in a particular array element, the kue\_oflags field usually identifies the error in more detail.

### **ERROR CODES**

If an error results, one of the following error values is returned:

Return Value	Description
EINVAL	The flags parameter is not KU_INTERCEPT, KU_INTERCEPT_STOP, nor KU_INTERCEPT_CANCEL.
	The fields in the header are invalid or the <i>blen</i> parameter is not consistent with the number of array elements.
	The buffer was invalid. For <b>KU_INTERCEPT</b> , at least one of the <b>pre-sc</b> and <b>post-sc</b> must be supplied for each system call to be intercepted. All <b>pre-sc</b> and <b>post-sc</b> functions must be in the same kernel extension as the caller of <b>kmod_util()</b> .
EBUSY	A request was made to intercept a system call that was already being intercepted.
ENOENT	A request was made to stop or cancel interception of a system call that was not being intercepted.
ENOMEM	Memory could not be allocated to satisfy the request.
ENOTSUPP	One of the specified system calls is not allowed to be intercepted.

### **Related Information**

The kmod load kernel service. The kmod unload kernel service. Kernel Extension and Device Driver Management Kernel Services in Kernel Extensions and Device Support Programming Concepts.

## kmsgctl Kernel Service

## **Purpose**

Provides message-queue control operations.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/ipc.h>
#include <sys/msg.h>
int kmsgctl (msqid, cmd, buf)
int msqid, cmd;
struct msqid ds *buf;
```

### **Parameters**

Specifies the message queue ID, which indicates the message queue for which the control operation is msqid being requested for.

cmd Specifies which control operation is being requested. There are three valid commands.

Points to the msqid ds structure provided by the caller of the kmsqctl service. Data is obtained either buf from this structure or from status returned in this structure, depending on the cmd parameter. The

msqid\_ds structure is defined in the /usr/include/sys/msg.h file.

# **Description**

The kmsgctl kernel service provides a variety of message-queue control operations as specified by the cmd parameter. The kmsgctl kernel service provides the same functions for user-mode processes in kernel mode as the msqctl subroutine performs for kernel processes or user-mode processes in user mode. The kmsqctl service can be called by a user-mode process in kernel mode or by a kernel process. A kernel process can also call the **msqctl** subroutine to provide the same function.

The following three commands can be specified with the *cmd* parameter:

**IPC STAT** IPC SET

Sets only documented fields. See the **msgctl** subroutine.

Sets the value of the following fields of the data structure associated with the msqid parameter to the corresponding values found in the structure pointed to by the buf parameter:

- msg perm.uid
- · msg perm.gid
- msg perm.mode (only the low-order 9 bits)
- msg qbytes

To perform the IPC SET operation, the current process must have an effective user ID equal to the value of the msg perm.uid or msg perm.cuid field in the data structure associated with the msgid parameter. To raise the value of the msg\_qbytes field, the calling process must have the appropriate system privilege.

**IPC RMID** 

Removes from the system the message-queue identifier specified by the msqid parameter. This operation also destroys both the message queue and the data structure associated with it. To perform this operation, the current process must have an effective user ID equal to the value of the msg perm.uid or msg perm.cuid field in the data structure associated with the msqid parameter.

## **Execution Environment**

The **kmsgctl** kernel service can be called from the process environment only.

### **Return Values**

Indicates successful completion.

**EINVAL** Indicates either

- The identifier specified by the msqid parameter is not a valid message queue identifier.
- The command specified by the *cmd* parameter is not a valid command.

**EACCES** The command specified by the cmd parameter is equal to IPC STAT and read permission is denied to

the calling process.

**EPERM** The command specified by the cmd parameter is equal to IPC\_RMID, IPC\_SET, and the effective user

ID of the calling process is not equal to that of the value of the msg perm.uid field in the data structure

associated with the *msqid* parameter.

**EPERM** Indicates the following conditions:

• The command specified by the cmd parameter is equal to IPC\_SET.

· An attempt is being made to increase to the value of the msg gbytes field, but the calling process does not have the appropriate system privilege.

## **Related Information**

The msgctl subroutine.

Message Queue Kernel Services and Understanding System Call Execution in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kmsgget Kernel Service

# **Purpose**

Obtains a message queue identifier.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/stat.h>
#include <sys/ipc.h>
#include <sys/msg.h>
int kmsgget ( key, msgflg, msqid)
key t key;
int msgflg;
int *msqid;
```

## **Parameters**

Specifies either a value of IPC\_PRIVATE or an IPC key constructed by the ftok subroutine (or a similar key algorithm).

Specifies that the *msgflg* parameter is constructed by logically ORing one or more of these values: msgflg

### **IPC\_CREAT**

Creates the data structure if it does not already exist.

#### IPC EXCL

Causes the kmsqqet kernel service to fail if IPC CREAT is also set and the data structure already exists.

#### S IRUSR

Permits the process that owns the data structure to read it.

#### S IWUSR

Permits the process that owns the data structure to modify it.

#### S IRGRP

Permits the process group associated with the data structure to read it.

#### S IWGRP

Permits the process group associated with the data structure to modify it.

#### S IROTH

Permits others to read the data structure.

#### S\_IWOTH

Permits others to modify the data structure.

The values that begin with S\_I... are defined in the /usr/include/sys/stat.h file. They are a subset of the access permissions that apply to files.

msqid

A reference parameter where a valid message-queue ID is returned if the kmsgget kernel service is successful.

## **Description**

The **kmsgget** kernel service returns the message-queue identifier specified by the *msgid* parameter associated with the specified key parameter value. The kmsgget kernel service provides the same functions for user-mode processes in kernel mode as the msgget subroutine performs for kernel processes or user-mode processes in user mode. The kmsgget service can be called by a user-mode process in kernel mode or by a kernel process. A kernel process can also call the msgget subroutine to provide the same function.

### **Execution Environment**

The **kmsgget** kernel service can be called from the process environment only.

#### **Return Values**

Indicates successful completion. The msqid parameter is set to a valid message-queue identifier.

If the **kmsgget** kernel service fails, the *msgid* parameter is not valid and the return code is one of these four values:

**EACCES** Indicates that a message queue ID exists for the key parameter but operation permission as specified by the *msgflg* parameter cannot be granted.

**ENOENT** Indicates that a message queue ID does not exist for the key parameter and the IPC\_CREAT command is not set.

Indicates that a message queue ID is to be created but the system-imposed limit on the maximum **ENOSPC** number of allowed message queue IDs systemwide will be exceeded.

**EEXIST** Indicates that a message queue ID exists for the value specified by the key parameter, and both the IPC\_CREAT and IPC\_EXCL commands are set.

## **Related Information**

The **msgget** subroutine.

Message Queue Kernel Services and Understanding System Call Execution in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kmsgrcv Kernel Service

## **Purpose**

Reads a message from a message queue.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/ipc.h>
#include <sys/msg.h>
int kmsgrcv
(msqid, msgp, msgsz,
msgtyp, msgflg, flags, bytes)
int msqid;
struct msgxbuf * msgp;
   or struct msgbuf *msgp;
int msqsz;
mtyp t msgtyp;
int msgflg;
int flags;
ssize_t * bytes;
```

### **Parameters**

msqid

Specifies the message queue from which to read.

msgp

Points to either an msgxbuf or an msgbuf structure where the message text is placed. The type of structure pointed to is determined by the values of the flags parameter. These structures are defined in the /usr/include/sys/msg.h file.

msgsz

Specifies the maximum number of bytes of text to be received from the message queue. The received message is truncated to the size specified by the msgsz parameter if the message is longer than this size and MSG\_NOERROR is set in the msgflg parameter. The truncated part of the message is lost and no indication of the truncation is given to the calling process.

msgtyp

Specifies the type of message requested as follows:

- If the msgtyp parameter is equal to 0, the first message on the queue is received.
- If the msqtyp parameter is greater than 0, the first message of the type specified by the msqtyp parameter is received.
- If the msqtyp parameter is less than 0, the first message of the lowest type that is less than or equal to the absolute value of the *msgtyp* parameter is received.

Specifies a value of 0, or is constructed by logically ORing one of several values: msgflg

#### **MSG NOERROR**

Truncates the message if it is longer than the number of bytes specified by the msgsz

#### **IPC NOWAIT**

Specifies the action to take if a message of the desired type is not on the queue:

- If IPC\_NOWAIT is set, then the kmsgrcv service returns an ENOMSG value.
- · If IPC\_NOWAIT is not set, then the calling process suspends execution until one of the following occurs:
  - A message of the desired type is placed on the queue.
  - The message queue ID specified by the msqid parameter is removed from the system. When this occurs, the **kmsgrcv** service returns an **EIDRM** value.
  - The calling process receives a signal that is to be caught. In this case, a message is not received and the kmsgrcv service returns an EINTR value.

Specifies a value of 0 if a normal message receive is to be performed. If an extended message receive is flags to be performed, this flag should be set to an XMSG value. With this flag set, the kmsgrcv service functions as the msgxrcv subroutine would. Otherwise, the kmsgrcv service functions as the msgrcv

subroutine would.

Specifies a reference parameter. This parameter contains the number of message-text bytes read from bytes the message queue upon return from the kmsgrcv service.

> If the message is longer than the number of bytes specified by the msgsz parameter bytes but MSG\_NOERROR is not set, then the kmsgrcv kernel service fails and returns an E2BIG return value.

## **Description**

The **kmsgrcv** kernel service reads a message from the queue specified by the *msqid* parameter and stores the message into the structure pointed to by the *msgp* parameter. The **kmsgrcv** kernel service provides the same functions for user-mode processes in kernel mode as the msgrcv and msgxrcv subroutines perform for kernel processes or user-mode processes in user mode.

The **kmsgrcv** service can be called by a user-mode process in kernel mode or by a kernel process. A kernel process can also call the **msgrcv** and **msgxrcv** subroutines to provide the same functions.

### **Execution Environment**

The **kmsgrcv** kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful operation.

EINVAL Indicates that the ID specified by the msqid parameter is not a valid message queue ID.

**EACCES** Indicates that operation permission is denied to the calling process. EINVAL Indicates that the value of the *msgsz* parameter is less than 0.

E2BIG Indicates that the message text is greater than the maximum length specified by the msgsz parameter

and MSG\_NOERROR is not set.

ENOMSG Indicates that the queue does not contain a message of the desired type and IPC\_NOWAIT is set.

**EINTR** Indicates that the kmsgrcv service received a signal.

**EIDRM** Indicates that the message queue ID specified by the msqid parameter has been removed from the

system.

### **Related Information**

The **msgrcv** subroutine, **msgxrcv** subroutine.

Message Queue Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

Understanding System Call Execution in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kmsgsnd Kernel Service

## **Purpose**

Sends a message using a previously defined message queue.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/ipc.h>
#include <sys/msg.h>
int kmsgsnd (msqid, msqp, msqsz, msqflq)
int msaid:
struct msgbuf * msgp;
int msgsz, msgflg;
```

### **Parameters**

msqid	Specifies the message queue ID that indicates which message queue the message is to be sent on.
msgp	Points to an msgbuf structure containing the message. The msgbuf structure is defined in the
	/usr/include/sys/msg.h file.
msgsz	Specifies the size of the message to be sent in bytes. The <i>msgsz</i> parameter can range from 0 to a
	system-imposed maximum.
msafla	Specifies the action to be taken if the message cannot be sent for one of several reasons.

# **Description**

The **kmsqsnd** kernel service sends a message to the queue specified by the *msqid* parameter. The kmsgsnd kernel service provides the same functions for user-mode processes in kernel mode as the msgsnd subroutine performs for kernel processes or user-mode processes in user mode. The kmsgsnd service can be called by a user-mode process in kernel mode or by a kernel process. A kernel process can also call the **msgsnd** subroutine to provide the same function.

There are two reasons why the **kmsgsnd** kernel service cannot send the message:

- The number of bytes already on the queue is equal to the msq qbytes member.
- The total number of messages on all queues systemwide is equal to a system-imposed limit.

There are several actions to take when the **kmsqsnd** kernel service cannot send the message:

- If the msqflq parameter is set to IPC\_NOWAIT, then the message is not sent, and the kmsgsnd service fails and returns an EAGAIN value.
- If the msgflg parameter is 0, then the calling process suspends execution until one of the following occurs:
  - The condition responsible for the suspension no longer exists, in which case the message is sent.
  - The message queue ID specified by the *msqid* parameter is removed from the system. When this occurs, the kmsgsnd service fails and an EIDRM value is returned.
  - The calling process receives a signal that is to be caught. In this case, the message is not sent and the calling process resumes execution as described in the sigaction kernel service.

### **Execution Environment**

The **kmsgsnd** kernel service can be called from the process environment only.

The calling process must have write permission to perform the **kmsgsnd** operation.

### **Return Values**

Indicates a successful operation.

EINVAL Indicates that the *msgid* parameter is not a valid message queue ID. **EACCES** Indicates that operation permission is denied to the calling process.

**EAGAIN** Indicates that the message cannot be sent for one of the reasons stated previously, and the msaflq

parameter is set to IPC\_NOWAIT.

**EINVAL** Indicates that the msgsz parameter is less than 0 or greater than the system-imposed limit.

**EINTR** Indicates that the kmsgsnd service received a signal.

**EIDRM** Indicates that the message queue ID specified by the msqid parameter has been removed from the

system.

ENOMEM Indicates that the system does not have enough memory to send the message.

### Related Information

## kra\_attachrset Subroutine

## **Purpose**

Attaches a work component to a resource set.

# **Syntax**

```
#include <sys/rset.h>
int kra attachrset (rstype, rsid, rset, flags)
rstype_t rstype;
rsid_t rsid;
rsethandle t rset;
unsigned int flags;
```

# **Description**

The **kra\_attachrset** subroutine attaches a work component specified by the *rstype* and *rsid* parameters to a resource set specified by the rset parameter.

The work component is an existing process identified by the process ID or an existing kernel thread identified by the kernel thread ID (tid). A process ID or thread ID value of RS\_MYSELF indicates the attachment applies to the current process or the current kernel thread, respectively.

The following conditions must be met to successfully attach a process to a resource set:

- The resource set must contain processors that are available in the system.
- The calling process must either have root authority or have CAP\_NUMA\_ATTACH capability.
- The calling process must either have root authority or the same effective userid as the target process.
- The target process must not contain any threads that have bindprocessor bindings to a processor.
- The resource set must be contained in (be a subset of) the target process' partition resource set.

The resource set must be a superset of all the thread's rset in the target process.

The following conditions must be met to successfully attach a kernel thread to a resource set:

- The resource set must contain processors that are available in the system.
- The calling process must either have root authority or have CAP\_NUMA\_ATTACH capability.
- The calling process must either have root authority or the same effective userid as the target process.
- The target thread must not have bindprocessor bindings to a processor.
- · The resource set must be contained in (be a subset of ) the target thread's process effective and partition resource set.

If any of these conditions are not met, the attachment will fail.

Once a process is attached to a resource set, the threads in the process will only run on processors contained in the resource set. Once a kernel thread is attached to a resource set, that thread will only run on processors contained in the resource set.

The flags parameter can be set to indicate the policy for using the resources contained in the resource set specified in the rset parameter. The only supported scheduling policy is R ATTACH STRSET, which is useful only when the processors of the system are running in simultaneous multithreading mode. Processors like the POWER5<sup>™</sup> support simultaneous multithreading, where each physical processor has two execution engines, called hardware threads. Each hardware thread is essentially equivalent to a single CPU, and each is identified as a separate CPU in a resource set. The R ATTACH STRSET flag indicates that the process is to be scheduled with a single-threaded policy; namely, that it should be scheduled on only one hardware thread per physical processor. If this flag is specified, then all of the available processors indicated in the resource set must be of exclusive use. A new resource set, called an ST resource set, is constructed from the specified resource set and attached to the process according to the following rules:

- All offline processors are ignored.
- If all the hardware threads (CPUs) of a physical processor (when running in simultaneous multithreading mode, there will be more than one active hardware thread per physical processor) are not included in the specified resource set, the other CPUs of the processor are ignored when constructing the ST resource set.
- Only one CPU (hardware thread) resource per physical processor is included in the ST resource set.

#### **Parameters**

Specifies the type of work component to be attached to the resource set specified by the rset parameter. rstype The *rstype* parameter must be the following value, defined in **rset.h**:

- R\_PROCESS: existing process
- R THREAD: existing kernel thread

Identifies the work component to be attached to the resource set specified by the rset parameter. The rsid parameter must be the following:

- Process ID (for rstype of R\_PROCESS): set the rsid\_t at\_pid field to the desired process' process ID.
- · Kernel thread ID (for rstype of R\_THREAD): set the rsid\_t at\_tid field to the desired kernel thread's

Specifies which work component (specified by the rstype and rsid parameters) to attach to the resource rset

Specifies the scheduling policy for the work component being attached. flags

> The only supported value is R\_ATTACH\_STRSET value, which is only applicable if the rstype parameter is set to R\_PROCESS. The R\_ATTACH\_STRSET value indicates that the process is to be scheduled with a single-threaded policy (only on one hardware thread per physical processor).

rsid

## **Return Values**

Upon successful completion, the kra\_attachrset subroutine returns a 0. If unsuccessful, one or more of the following are true:

#### **EINVAL**

One of the following is true:

- The *flags* parameter contains an invalid value.
- The rstype parameter contains an invalid type qualifier.
- The R ATTACH STRSET flags parameter is specified and one or more processors in the rset parameter are not assigned for exclusive use.

#### **ENODEV**

The resource set specified by the rset parameter does not contain any available processors, or the R ATTACH STRSET flags parameter is specified and the constructed ST resource set does not have any available processors.

#### **ESRCH EPERM**

The process or kernel thread identified by the rstype and rsid parameters does not exist.

One of the following is true:

- If the rstype is R\_PROCESS, either the resource set specified by the rset parameter is not included in the partition resource set of the process identified by the rstype and rsid parameters, or any of the thread's R\_THREAD rset in this process is not a subset of the resource set specified by the rset parameter.
- · If the rstype is R\_THREAD, the resource set specified by the rset parameter is not included in the target thread's process effective or partition (real) resource set.
- The calling process has neither root authority nor CAP\_NUMA\_ATTACH attachment privilege.
- · The calling process has neither root authority nor the same effective user ID as the process identified by the rstype and rsid parameters.
- The process or thread identified by the rstype and rsid parameters has one or more threads with a bindprocessor processor binding.

## **Related Information**

For information on exclusive processors, see Exclusive use processor resource sets in AIX Version 7.1 Operating system and device management.

# kra\_creatp Subroutine

# Purpose

Creates a new kernel process and attaches it to a resource set.

# **Syntax**

#include <sys/rset.h> int kra creatp (pid, rstype, rsid, flags) pid t \*pid; rstype\_t rstype; rsid\_t rsid; unsigned int flags;

# Description

The kra\_creatp kernel service creates a new kernel process and attaches it to a resource set. The kra creatp kernel service attaches the new kernel process to the resource set specified by the rstype and rsid parameters.

The kra\_creatp kernel service is similar to the creatp kernel service. See the "creatp Kernel Service" on page 56 for details on creating a new kernel process.

The following conditions must be met to successfully attach a kernel process to a resource set:

- The resource set must contain processors that are available in the system.
- The calling process must either have root authority or have CAP\_NUMA\_ATTACH capability.
- The calling thread must not have a bindprocessor binding to a processor.
- The resource set must be contained in the calling process' partition resource set.

**Note:** When the **creatp** kernel service is used, the new kernel process inherits its parent's resource set attachments.

### **Parameters**

pid Pointer to a pid\_t field to receive the process ID of the new kernel process.

rstype Specifies the type of resource the new process will be attached to. This parameter must be the

following value, defined in rset.h.

R\_RSET: resource set.

rsid Identifies the resource set the new process will be attached to.

Resource set ID (for rstype of R\_RSET): set the rsid\_t at\_rset field to the desired resource set.

flags Reserved for future use. Specify as 0.

### **Return Values**

Upon successful completion, the **kra\_creatp** kernel service returns a 0. If unsuccessful, one or more of the following are true:

**EINVAL** One of the following is true:

• The rstype parameter contains an invalid type identifier.

• The flags parameter contains an invalid flags value.

**ENODEV** The specified resource set does not contain any available processors.

**EFAULT** Invalid address.

**EPERM** One of the following is true:

The calling process has neither root authority nor CAP\_NUMA\_ATTACH attachment privilege.

· The calling process contains one or more threads with a bindprocessor processor binding.

• The specified resource set is not included in the calling process' partition resource set.

**ENOMEM** Memory not available.

## **Related Information**

# kra\_detachrset Subroutine

# **Purpose**

Detaches a work component from a resource set.

# **Syntax**

```
#include <sys/rset.h>
int kra_detachrset (rstype, rsid, flags)
rstype_t rstype;
rsid_t rsid;
unsigned int flags;
```

## **Description**

The kra detachrset subroutine detaches a work component specified by rstype and rsid from a resource set.

The work component is an existing process identified by the process ID or an existing kernel thread identified by the kernel thread ID (tid). A process ID or thread ID value of RS\_MYSELF indicates the detach command applies to the current process or the current kernel thread, respectively.

The following conditions must be met to detach a process or kernel thread from a resource set:

- The calling process must either have root authority or have CAP\_NUMA\_ATTACH capability.
- The calling process must either have root authority or the same effective userid as the target process.

If these conditions are not met, the operation will fail.

Once a process is detached from a resource set, the threads in the process can run on all available processors contained in the process' partition resource set. Once a kernel thread is detached from a resource set, that thread can run on all available processors contained in its process effective or partition resource set.

### **Parameters**

Specifies the type of work component to be detached from to the resource set specified by rset. This rstype parameter must be the following value, defined in rset.h:

- · R\_PROCESS: existing process
- R\_THREAD: existing kernel thread

rsid Identifies the work component to be attached to the resource set specified by rset. This parameter must be the following:

- Process ID (for rstype of R PROCESS): set the rsid t at pid field to the desired process' process ID.
- Kernel thread ID (for rstype of R\_THREAD): set the rsid\_t at\_tid field to the desired kernel thread's thread

flags

For rstype of R\_PROCESS, the R\_DETACH\_ALLTHRDS indicates that R\_THREAD rsets are detached from all threads in a specified process. The process' effective rset is not detached in this case. Reserved for future use. Specify as 0.

### **Return Values**

Upon successful completion, the kra detachrset subroutine returns a 0. If unsuccessful, one or more of the following are true:

**EINVAL** One of the following is true:

- The flags parameter contains an invalid value.
- The rstype contains an invalid type qualifier.

**ESRCH** 

The process or kernel thread identified by the rstype and rsid parameters does not exist.

**EPERM** One of the following is true:

- The calling process has neither root authority nor CAP\_NUMA\_ATTACH attachment privilege.
- · The calling process has neither root authority nor the same effective user ID as the process identified by the rstype and rsid parameters.

### **Related Information**

The "kra attachrset Subroutine" on page 293.

## kra\_getrset Subroutine

## **Purpose**

Gets the resource set to which a work component is attached.

## **Syntax**

```
#include <sys/rset.h>
int kra_getrset (rstype, rsid, flags, rset, rset_type)
rstype_t rstype;
rsid_t rsid;
unsigned int flags;
rsethandle_t rset;
unsigned int *rset type;
```

## Description

The kra\_getrset subroutine returns the resource set to which a specified work component is attached.

The work component is an existing process identified by the process ID or an existing kernel thread identified by the kernel thread ID (tid). A process ID or thread ID value of RS\_MYSELF indicates the resource set attached to the current process or the current kernel thread, respectively, is requested.

Upon successful completion, one of the following types of resource set is returned into the *rset\_type* parameter:

- A value of RS\_EFFECTIVE\_RSET indicates the process was explicitly attached to the resource set.
   This may have been done with the kra\_attachrset subroutine.
- A value of RS\_PARTITION\_RSET indicates the process was not explicitly attached to a resource set.
   However, the process had an explicitly set partition resource set. This may be set with the
   krs\_setpartition subroutine or through the use of WLM work classes with resource sets.
- A value of RS\_DEFAULT\_RSET indicates the process was not explicitly attached to a resource set nor
  did it have an explicitly set partition resource set. The system default resource set is returned.
- A value of RS\_THREAD\_RSET indicates the kernel thread was explicitly attached to the resource set. This might have been done with the **ra\_attachrset** subroutine.

### **Parameters**

rstype

Specifies the type of the work component whose resource set attachment is requested. This parameter must be the following value, defined in **rset.h**:

- · R\_PROCESS: existing process
- · R\_THREAD: existing kernel thread

rsid

Identifies the work component whose resource set attachment is requested. This parameter must be the following:

- Process ID (for rstype of R\_PROCESS): set the rsid\_t at\_pid field to the desired process' process ID.
- Kernel thread ID (for rstype of R\_THREAD): set the rsid\_t at\_tid field to the desired kernel thread's thread ID.

flags Reserved for future use. Specify as 0.

rset Specifies the resource set to receive the work component's resource set.

rset\_type Points to an unsigned integer field to receive the resource set type.

## **Return Values**

Upon successful completion, the **kra\_getrset** subroutine returns a 0. If unsuccessful, one or more of the following are true:

EINVAL One of the following is true:

· The flags parameter contains an invalid value.

· The rstype parameter contains an invalid type qualifier.

**EFAULT** Invalid address.

**ESRCH** The process or kernel thread identified by the rstype and rsid parameters does not exist.

## **Related Information**

The "krs\_getpartition Subroutine" on page 303.

## krs\_alloc Subroutine

## Purpose

Allocates a resource set and returns its handle.

## **Syntax**

#include <sys/rset.h> int krs\_alloc (rset, flags) rsethandle t \*rset; unsigned int flags;

## **Description**

The krs\_alloc subroutine allocates a resource set and initializes it according to the information specified by the *flags* parameter. The value of the *flags* parameter determines how the new resource set is initialized.

### **Parameters**

rset Points to an rsethandle\_t where the resource set handle is stored on successful completion. flags

Specifies how the new resource set is initialized. It takes one of the following values, defined in rset.h:

- RS\_EMPTY (or 0 value): The resource set is initialized to contain no resources.
- RS\_SYSTEM: The resource set is initialized to contain available system resources.
- · RS\_ALL: The resource set is initialized to contain all resources.
- RS\_PARTITION: The resource set is initialized to contain the resources in the caller's process partition resource set.

## **Return Values**

Upon successful completion, the krs\_alloc subroutine returns a 0. If unsuccessful, one or more of the following is returned:

**EINVAL** The flags parameter contains an invalid value.

**ENOMEM** There is not enough space to create the data structures related to the resource set.

## **Related Information**

"krs\_free Subroutine" on page 300, "krs\_getinfo Subroutine" on page 301, and "krs\_init Subroutine" on page 304.

## krs\_free Subroutine

# **Purpose**

Frees a resource set.

## **Syntax**

```
#include <sys/rset.h>
void krs free(rset)
rsethandle_t rset;
```

## Description

The krs\_free subroutine frees a resource set identified by the rset parameter. The resource set must have been allocated by the krs\_alloc subroutine.

### **Parameters**

rset

Specifies the resource set whose memory will be freed.

## **Related Information**

The "krs\_alloc Subroutine" on page 299.

## krs\_getassociativity Subroutine

## **Purpose**

Gets the hardware associativity values for a resource.

# **Syntax**

```
#include <sys/rset.h>
int krs_getassociativity (type, id, assoc array, array size)
unsigned int type;
unsigned int id;
unsigned int *assoc array;
unsigned int array size;
```

# Description

The krs\_getassociativity subroutine returns the array of hardware associativity values for a specified resource.

This is a special purpose subroutine intended for specialized root applications needing the hardware associativity value information. The krs getinfo, krs getrad, and krs numrads subroutines are provided for typical applications to discover system hardware topology.

The calling process must have root authority to get hardware associativity values.

#### **Parameters**

type Specifies the resource type whose associativity values are requested. The only value supported to

retrieve values for a processor is R\_PROCS.

Specifies the logical resource id whose associativity values are requested. id

assoc\_array Specifies the address of an array of unsigned integers to receive the associativity values.

Specifies the number of unsigned integers in assoc\_array. array\_size

## **Return Values**

Upon successful completion, the krs\_getassociativity subroutine returns a 0. The assoc\_array parameter array contains the resource's associativity values. The first entry in the array indicates the number of associativity values returned. If the hardware system does not provide system topology data, a value of 0 is returned in the first array entry. If unsuccessful, one or more of the following are returned:

**EINVAL** One of the following occurred:

• The array\_size parameter was specified as 0.

· An invalid type parameter was specified.

**ENODEV** The resource specified by the *id* parameter does not exist.

**EFAULT** Invalid address.

**EPERM** The calling process does not have root authority.

## **Related Information**

"krs getinfo Subroutine," "krs getrad Subroutine" on page 304, and "krs numrads Subroutine" on page 305.

## krs get homesrad Subroutine

## **Purpose**

Gets the currently running thread's home SRADID (Scheduler Resource Allocation Domain Identifier).

## Library

Standard C library (libc.a)

# **Syntax**

#include <sys/rset.h> sradid\_t krs\_get\_homesrad(void)

# **Description**

The krs get homesrad is a kernel service and if the ENHANCED AFFINITY services are enabled, the krs get homesrad subroutine returns the home SRADID of the currently running thread. If the ENHANCED\_AFFINITY services are not enabled, the krs\_get\_homesrad subroutine returns SRADID ANY. SRADID is the index of a RAD (Resource Allocation Domain) at the R SRADSDL system detail level. See the "krs getrad Subroutine" on page 304 subroutine for information about obtaining a resource set that corresponds to a returned SRADID.

### **Return Values**

If the ENHANCED AFFINITY services are enabled, the home SRADID of the currently running thread is returned. Otherwise, SRADID ANY is returned.

### **Related Information**

"krs getrad Subroutine" on page 304

# krs\_getinfo Subroutine

# **Purpose**

Gets information about a resource set.

## **Syntax**

```
#include <sys/rset.h>
int krs_getinfo(rset, info_type, flags, result)
rsethandle t rset;
rsinfo_t info type;
unsigned int flags;
int *result;
```

## Description

The **krs getinfo** subroutine retrieves information about the resource set identified by the *rset* parameter. Depending on the value of the info\_type parameter, the krs\_getinfo subroutine returns information about the number of available processors, the number of available memory pools, or the amount of available memory contained in the resource rset.

The subroutine can also return global system information such as the maximum system detail level, the symmetric multiprocessor (SMP) and multiple chip module (MCM) system detail levels, and the maximum number of processor or memory pool resources in a resource set.

### **Parameters**

rset

Specifies a resource set handle of a resource set the information should be retrieved from. This parameter is not meaningful if the info\_type parameter is R\_MAXSDL, R\_MAXPROCS, R\_MAXMEMPS, R\_SMPSDL, or R\_MCMSDL.

info\_type

Specifies the type of information being requested. One of the following values (defined in rset.h) can be used:

- R NUMPROCS: The number of available processors in the resource set is returned.
- R\_NUMMEMPS: The number of available memory pools in the resource set is returned.
- R MEMSIZE: The amount of available memory (in MB) contained in the resource set is returned.
- · R\_MAXSDL: The maximum system detail level of the system is returned.
- R MAXPROCS: The maximum number of processors that may be contained in a resource set is returned.
- R\_MAXMEMPS: The maximum number of memory pools that may be contained in a resource set is
- R SMPSDL: The system detail level that corresponds to the traditional notion of an SMP is returned. A system detail level of 0 is returned if the hardware system does not provide system topology data.
- R\_MCMSDL: The system detail level that corresponds to resources packaged in an MCM is returned. A system detail level of 0 is returned if the hardware system does not have MCMs or does not provide system topology data.

flags

Reserved for future use. Must be specified as 0.

result

Points to an integer where the result is stored on successful completion.

## **Return Values**

Upon successful completion, the krs getinfo subroutine returns a 0, and the result field contains the requested information. If unsuccessful, one or more of the following are returned:

**EINVAL** 

One of the following is true:

- The info\_type parameter specifies an invalid resource type value.
- The flags parameter was not specified as 0.

**EFAULT** 

Invalid address.

## **Related Information**

The "krs\_numrads Subroutine" on page 305.

## krs\_getpartition Subroutine

## **Purpose**

Gets the partition resource set to which a process is attached.

## **Syntax**

```
#include <sys/rset.h>
int krs_getpartition (pid, flags, rset, rset_type)
pid_t pid;
unsigned int flags;
rsethandle_t rset;
unsigned int *rset type;
```

## **Description**

The **krs\_getpartition** subroutine returns the partition resource set attached to the specified process. A process ID value of RS\_MYSELF indicates the partition resource set attached to the current process is requested.

Upon successful completion, the type of resource set is returned into the *rset\_type* parameter.

A value of RS\_PARTITION\_RSET indicates the process has a partition resource set that is set explicitly. This may be set with the **krs\_setpartition** subroutine or through the use of WLM work classes with resource sets.

A value of RS\_DEFAULT\_RSET indicates the process did not have an explicitly set partition resource set. The system default resource set is returned.

## **Parameters**

pid Specifies the process ID whose partition rset is requested.

flags Reserved for future use. Specify as 0.

*rset* Specifies the resource set to receive the process' partition resource set. *rset\_type* Points to an unsigned integer field to receive the resource set type.

#### **Return Values**

Upon successful completion, the **krs\_getpartition** subroutine returns a 0. If unsuccessful, one or more of the following are true:

**EFAULT** Invalid address.

**ESRCH** The process identified by the *pid* parameter does not exist.

## **Related Information**

The "kra\_getrset Subroutine" on page 298.

## krs\_getrad Subroutine

## **Purpose**

Returns a system resource allocation domain (RAD) contained in an input resource set.

## **Syntax**

```
#include <sys/rset.h>
int krs_getrad (rad, sdl, index, flags)
rsethandle_t rad;
unsigned int sdl;
unsigned int index;
unsigned int flags;
```

## **Description**

The krs\_getrad subroutine returns a system RAD at a specified system detail level and index.

The system RAD is specified by system detail level sdl and index number index.

The *rad* parameter must be allocated (using the **krs\_alloc** subroutine) prior to calling the **krs\_getrad** subroutine.

### **Parameters**

rad Specifies a resource set handle to receive the desired system RAD.

sdl Specifies the system detail level of the desired system RAD.

index Specifies the index of the system RAD that should be returned from among those at the specified sdl. This

parameter must belong to the [0, krs\_numrads(rset, sdl, flags)-1] interval.

flags Reserved for future use. Specify as 0.

#### **Return Values**

Upon successful completion, the **krs\_getrad** subroutine returns a 0. If unsuccessful, one or more of the following are true:

**EINVAL** One of the following is true:

- · The flags parameter contains an invalid value.
- The sdl parameter is greater than the maximum system detail level.
- The RAD specified by the index parameter does not exist at the system detail level specified by the sdl parameter.

**EFAULT** Invalid address.

## **Related Information**

"krs\_numrads Subroutine" on page 305, "krs\_getinfo Subroutine" on page 301, "krs\_alloc Subroutine" on page 299, and "krs\_op Subroutine" on page 306.

# krs\_init Subroutine

# **Purpose**

Initializes a previously allocated resource set.

## **Syntax**

```
#include <sys/rset.h>
int krs_init (rset, flags)
rsethandle_t rset;
unsigned int flags;
```

## **Description**

The **krs\_init** subroutine initializes a previously allocated resource set. The resource set is initialized according to information specified by the *flags* parameter.

### **Parameters**

rset

Specifies the handle of the resource set to initialize.

flags

Specifies how the resource set is initialized. It takes one of the following values, defined in rset.h:

- RS EMPTY: The resource set is initialized to contain no resources.
- RS\_SYSTEM: The resource set is initialized to contain available system resources.
- RS\_ALL: The resource set is initialized to contain all resources.
- RS\_PARTITION: The resource set is initialized to contain the resources in the caller's process partition resource set.

### **Return Values**

Upon successful completion, the krs init subroutine returns a 0. If unsuccessful, the following is returned:

**EINVAL** 

The *flags* parameter contains an invalid value.

### **Related Information**

The "krs\_alloc Subroutine" on page 299.

## krs\_numrads Subroutine

# **Purpose**

Returns the number of system resource allocation domains (RADs) that have available resources.

# **Syntax**

```
#include <sys/rset.h>
int krs_numrads(rset, sdl, flags)
rsethandle_t rset;
unsigned int sdl;
unsigned int flags;
```

# **Description**

The **krs\_numrads** subroutine returns the number of system RADs at system detail level *sdl*, that have available resources contained in the resource set identified by the *rset* parameter.

The number of atomic RADs contained in the *rset* parameter is returned if the *sdl* parameter is equal to the maximum system detail level.

### **Parameters**

rset Specifies the resource set handle for the resource set being queried.

sdl Specifies the system detail level in which the caller is interested.

Reserved for future use. Specify as 0. flags

## **Return Values**

Upon successful completion, the number of RADs is returned. If unsuccessful, a -1 is returned and one or more of the following are true:

- The flags parameter contains an invalid value.
- The sdl parameter is greater than the maximum system detail level.

### **Related Information**

"krs\_getrad Subroutine" on page 304, and "krs\_getinfo Subroutine" on page 301.

# krs\_op Subroutine

## **Purpose**

Performs a set of operations on one or two resource sets.

# **Syntax**

```
#include <sys/rset.h>
int krs_op (command, rset1, rset2, flags, id)
unsigned int command;
rsethandle_t rset1, rset2;
unsigned int flags;
unsigned int id;
```

# **Description**

The **krs\_op** subroutine performs the operation specified by the *command* parameter on resource set *rset1*, or both resource sets rset1 and rset2.

#### **Parameters**

command

Specifies the operation to apply to the resource sets identified by *rset1* and *rset2*. One of the following values, defined in **rset.h**, can be used:

- RS UNION: The resources contained in either rset1 or rset2 are stored in rset2.
- RS\_INTERSECTION: The resources that are contained in both rset1 and rset2 are stored in rset2.
- RS\_EXCLUSION: The resources in rset1 that are also in rset2 are removed from rset2. On
  completion, rset2 contains all the resources that were contained in rset2 but were not contained in
  rset1.
- RS\_COPY: All resources in rset1 whose type is flags are stored in rset2. If rset1 contains no
  resources of this type, rset2 will be empty. The previous content of rset2 is lost, while the content of
  rset1 is unchanged.
- RS\_ISEMPTY: Test if resource set rset1 is empty.
- RS\_ISEQUAL: Test if resource sets rset1 and rset2 are equal.
- RS\_ISCONTAINED: Test if all resources in resource set rset1 are also contained in resource set rset2
- RS\_TESTRESOURCE: Test if the resource whose type is *flags* and index is *id* is contained in resource set *rset1*.
- RS\_ADDRESOURCE: Add the resource whose type is flags and index is id to resource set rset1.
- RS\_DELRESOURCE: Delete the resource whose type is flags and index is id from resource set rset1.
- **RS\_STSET**: Constructs an ST resource set by including only one hardware thread per physical processor included in *rset1* and stores it in *rset2*. Only available processors are considered when constructing the ST resource set.

rset1 rset2 Specifies the resource set handle for the first of the resource sets involved in the *command* operation. Specifies the resource set handle for the second of the resource sets involved in the *command* operation. This resource set is also used, on return, to store the result of the operation, and its previous content is lost. The *rset2* parameter is ignored on the RS\_ISEMPTY, RS\_TESTRESOURCE, RS\_ADDRESOURCE, and RS\_DELRESOURCE commands.

flags

id

When combined with the RS\_COPY command, the *flags* parameter specifies the type of the resources that will be copied from *rset1* to *rset2*. This parameter is constructed by logically ORing one or more of the following values, defined in **rset.h**:

- R\_PROCS: processors
- R\_MEMPS: memory pools
- R\_ALL\_RESOURCES: processors and memory pools

If none of the above are specified for *flags*, R\_ALL\_RESOURCES is assumed. On the RS\_TESTRESOURCE, RS\_ADDRESOURCE, and RS\_DELRESOURCE commands, the *id* parameter specifies the index of the resource to be tested, added, or deleted. This parameter is ignored on the other commands.

#### **Return Values**

- Successful completion. The tested condition is not met for the RS\_ISEMPTY, RS\_ISEQUAL, RS\_ISCONTAINED, and RS\_TESTRESOURCE commands.
- 1 Successful completion. The tested condition is met for the RS\_ISEMPTY, RS\_ISEQUAL, RS\_ISCONTAINED, and RS\_TESTRESOURCE commands.

- -1 Unsuccessful completion. One or more of the following are true:
  - rset1 identifies an invalid resource set.
  - · rset2 identifies an invalid resource set.
  - · command identifies an invalid operation.
  - · flags identifies an invalid resource type.
  - id specifies a resource index that is too large.
  - Invalid address.

# krs\_setpartition Subroutine

# **Purpose**

Sets the partition resource set of a process.

# **Syntax**

```
#include <sys/rset.h>
int krs_setpartition(pid, rset, flags)
pid_t pid;
rsethandle t rset;
unsigned int flags;
```

# **Description**

The krs\_setpartition subroutine sets a process' partition resource set. The subroutine can also be used to remove a process' partition resource set.

The partition resource set limits the threads in a process to running only on the processors contained in the partition resource set.

The work component is an existing process identified by process ID. A process ID value of RS MYSELF indicates the attachment applies to the current process.

The following conditions must be met to set a process' partition resource set:

- The calling process must have root authority.
- The resource set must contain processors that are available in the system.
- · The new partition resource set must be equal to, or a superset of the target process' effective resource set.
- The target process must not contain any threads that have bindprocessor bindings to a processor.

The flags parameter can be set to indicate the policy for using the resources contained in the resource set specified in the rset parameter. The only supported scheduling policy is R\_ATTACH\_STRSET, which is useful only when the processors of the system are running in simultaneous multithreading mode. Processors like the POWER5<sup>™</sup> support simultaneous multithreading, where each physical processor has two execution engines, called hardware threads. Each hardware thread is essentially equivalent to a single CPU, and each is identified as a separate CPU in a resource set. The R\_ATTACH\_STRSET flag indicates that the process is to be scheduled with a single-threaded policy; namely, that it should be scheduled on only one hardware thread per physical processor. If this flag is specified, then all of the available processors indicated in the resource set must be of exclusive use. A new resource set, called an ST resource set, is constructed from the specified resource set and attached to the process according to the following rules:

All offline processors are ignored.

- If all the hardware threads (CPUs) of a physical processor (when running in simultaneous multithreading mode, there will be more than one active hardware thread per physical processor) are not included in the specified resource set, the other CPUs of the processor are ignored when constructing the ST resource set.
- Only one CPU (hardware thread) resource per physical processor is included in the ST resource set.

#### **Parameters**

pid Specifies the process ID of the process whose partition resource set is to be set. A value of RS\_MYSELF indicates the current process' partition resource set should be set.

rset Specifies the partition resource set to be set. A value of RS\_DEFAULT indicates the process' partition resource set should be removed.

flags Specifies the policy to use for the process. A value of R\_ATTACH\_STRSET indicates that the process is to be scheduled with a single-threaded policy (only on one hardware thread per physical processor).

#### **Return Values**

Upon successful completion, the **krs\_setpartition** subroutine returns a 0. If unsuccessful, one or more of the following are true:

**EINVAL** The R\_ATTACH\_STRSET *flags* parameter is specified and one or more processors in the *rset* 

parameter are not assigned for exclusive use.

**ENODEV** The resource set specified by the *rset* parameter does not contain any available processors, or the

R\_ATTACH\_STRSET flags parameter is specified and the constructed ST resource set does not have

any available processors.

**ESRCH** The process identified by the *pid* parameter does not exist.

**EFAULT** Invalid address.

**ENOMEM** Memory not available. **EPERM** One of the following is true:

· The calling process does not have root authority.

- The process identified by the pid parameter has one or more threads with a bindprocessor processor binding.
- The process identified by the pid parameter has an effective resource set and the new partition resource set identified by the rset parameter does not contain all of the effective resource set's resources.

## **Related Information**

"krs getpartition Subroutine" on page 303 and "kra attachrset Subroutine" on page 293.

For information about exclusive processors, see Exclusive use processor resource sets in *AIX Version 7.1 Operating system and device management*.

## ksettickd Kernel Service

# **Purpose**

Sets the current status of the systemwide timer-adjustment values.

# **Syntax**

```
#include <sys/types.h>
int ksettickd (timed, tickd, time_adjusted)
int *timed;
int *tickd;
int *time adjusted;
```

### **Parameters**

timed Specifies the number of microseconds by which the systemwide timer is to be adjusted

unless set to a null pointer.

tickd Specifies the adjustment rate of the systemwide timer unless set to a null pointer. This rate

determines the number of microseconds that the systemwide timer is adjusted with each timer tick. Adjustment continues until the time has been corrected by the amount specified

by the *timed* parameter.

Sets the kernel-maintained time adjusted flag to True or False. If the time adjusted time\_adjusted

parameter is a null pointer, calling the ksettickd kernel service always sets the kernel's

time\_adjusted parameter to False.

# **Description**

The ksettickd kernel service provides kernel extensions with the capability to update the time\_adjusted parameter, and set or change the systemwide time-of-day timer adjustment amount and rate. The timer-adjustment values indicated by the timed and tickd parameters are the same values used by the adjtime subroutine. A call to the settimer or adjtime subroutine for the systemwide time-of-day timer sets the time adjusted parameter to True, as read by the **kgettickd** kernel service.

This kernel service is typically used only by kernel extensions providing time synchronization functions such as coordinated network time where the adjtime subroutine is insufficient.

Note: The ksettickd service provides no serialization with respect to the adjtime and settimer subroutines, the ksettimer kernel service, or the timer interrupt handler, all of which also use and update these values. The caller of this kernel service must provide the necessary serialization to ensure appropriate operation.

## **Execution Environment**

The **ksettickd** kernel service can be called from either the process or interrupt environment.

#### Return Value

The ksettickd kernel service always returns a value of 0.

## Related Information

The kgettickd kernel service, ksettimer kernel service.

The adjtime subroutine, settimer subroutine.

Timer and Time-of-Day Kernel Services and Using Fine Granularity Timer Services and Structures in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## ksettimer Kernel Service

# **Purpose**

Sets the systemwide time-of-day timer.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/time.h>
int ksettimer (nct)
struct timestruc_t *nct;
```

## **Parameter**

nct

Points to a timestruc\_t structure, which contains the new current time to be set. The nanoseconds member of this structure is valid only if greater than or equal to 0, and less than the number of nanoseconds in a second.

# **Description**

The **ksettimer** kernel service provides a kernel extension with the capability to set the systemwide time-of-day timer. Kernel extensions typically use this kernel service to support network coordinated time, which is the periodic synchronization of all system clocks to a common time by a time server or set of time servers on a network. The newly set "current" time must represent the amount of time since 00:00:00 GMT, January 1, 1970.

## **Execution Environment**

The **ksettimer** kernel service can be called from the process environment only.

### Return Values

Indicates success.

**EINVAL** Indicates that the new current time specified by the nct parameter is outside the range of the systemwide

timer.

**EIO** Indicates that an error occurred while this kernel service was accessing the timer device.

### **Related Information**

Using Fine Granularity Timer Services and Structures and Timer and Time-of-Day Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kthread kill Kernel Service

# **Purpose**

Posts a signal to a specified kernel-only thread.

# **Syntax**

```
#include <sys/thread.h>
void kthread kill ( tid, sig)
tid t tid;
int sig;
```

#### **Parameters**

tid Specifies the target kernel-only thread. If its value is -1, the signal is posted to the calling thread.

Specifies the signal number to post. sig

# **Description**

The kthread\_kill kernel service posts the signal sig to the kernel thread specified by the tid parameter. When the service is called from the process environment, the target thread must be in the same process as the calling thread. When the service is called from the interrupt environment, the signal is posted to the target thread, without a permission check.

## **Execution Environment**

The kthread\_kill kernel service can be called from either the process environment or the interrupt environment.

### **Return Values**

The kthread kill kernel service has no return values.

### **Related Information**

The sig chk kernel service.

# kthread\_start Kernel Service

# **Purpose**

Starts a previously created kernel-only thread.

# **Syntax**

```
#include <sys/thread.h>
int kthread_start ( tid,  i_func,  i_data_addr,  i_data_len,  i_stackaddr,  i_sigmask)
tid t tid;
int (*i_func) (void *);
void *i data addr;
size t i data len;
void *i stackaddr;
sigset_t *i_sigmask;
```

#### **Parameters**

tid Specifies the kernel-only thread to start.

i func Points to the entry-point routine of the kernel-only thread. Points to data that will be passed to the entry-point routine. i\_data\_addr

Specifies the length of the data chunk. i\_data\_len

i\_stackaddr Specifies the stack's base address for the kernel-only thread.

Specifies the set of signal to block from delivery when the new kernel-only thread begins i\_sigmask

execution.

# **Description**

The kthread\_start kernel service starts the kernel-only thread specified by the tid parameter. The thread must have been previously created with the thread\_create kernel service, and its state must be TSIDL.

This kernel service initializes and schedules the thread for the processor. Its state is changed to TSRUN. The thread is initialized so that it begins executing at the entry point specified by the *i func* parameter, and that the signals specified by the *i sigmask* parameter are blocked from delivery.

The thread's entry point gets one parameter, a pointer to a chunk of data that is copied to the base of the thread's stack. The i data addr and i data len parameters specify the location and quantity of data to copy. The format of the data must be agreed upon by the initializing and initialized thread.

The thread's stack's base address is specified by the i\_stackaddr parameter. If a value of zero is specified, the kernel will allocate the memory for the stack (96K). This memory will be reclaimed by the system when the thread terminates. If a non-zero value is specified, then the caller should allocate the backing memory for the stack. Since stacks grow from high addresses to lower addresses, the i stackaddr parameter specifies the highest address for the thread's stack.

The thread will be automatically terminated when it returns from the entry point routine. If it is the last thread in the process, then the process will be exited.

## **Execution Environment**

The kthread\_start kernel service can be called from the process environment only.

## **Return Values**

The **kthread\_start** kernel service returns one of the following values:

Indicates a successful start.

ESRCH Indicates that the *tid* parameter is not valid.

## **Related Information**

The thread\_create kernel service.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kvmgetinfo Kernel Service

# **Purpose**

Retrieves Virtual Memory Manager (VMM) information.

# **Syntax**

#include <sys/vminfo.h>

int kvmgetinfo ( void \*out, int command, int arg)

# **Description**

The **kvmgetinfo** kernel service returns the current value of certain VMM parameters.

#### **Parameters**

out

Specifies the address where VMM information should be returned.

command

Specifies which information should be returned. The valid values for the command parameter are decribed below:

#### **VMINFO**

The content of vminfo structure (described in sys/vminfo.h) will be returned. The *out* parameter should point to a **vminfo** structure and the *arg* parameter should be the size of this structure. The smaller of the arg or sizeof (struct vminfo) parameters will be copied.

#### VMINFO\_ABRIDGED

The content of the vminfo structure (described in the sys/vminfo.h file) is returned. For this command, only the non-time consuming statistics are updated, so this command must be used in performance-critical applications rather than the VMINFO command. The out parameter must point to a vminfo structure and the arg parameter must be the size of this structure. The smaller of the arg or sizeof (struct vminfo) parameters are copied.

#### VM\_PAGE\_INFO

The size, in bytes, of the page backing the address specified in the addr field of the vm\_page\_info structure (described in the sys/vminfo.h file) is returned. The out parameter should point to a vm\_page\_info structure with the addr field set to the desired address of which to query the page size. This address, addr, is interpreted as an address in the address space of the current running process. The *arg* parameter should be the size of the **vm\_page\_info** structure.

## **IPC\_LIMITS**

The content of the ipc\_limits struct (described in the sys/vminfo.h file) is returned. The out parameter should point to an ipc limits structure and arg should be the size of this structure. The smaller of the arg or sizeof (struct ipc limits) parameters will be copied. The ipc limits struct contains the inter-process communication (IPC) limits for the system.

#### **VMINFO GETPSIZES**

Reports a system's supported page sizes. When arg is 0, the out parameter is ignored, and the number of supported page sizes is returned. When arg is greater than 0, arg indicates the number of page sizes to report, and out must be a pointer to an array with arg number of psize\_t types. The array of psize\_t types is updated with the system's supported page sizes in sorted order starting with the smallest supported page size. The number of array entries updated with page sizes is returned.

#### **VMINFO PSIZE**

Reports detailed VMM statistics for a specified page size. The out parameter must point to a vminfo\_psize structure with the psize field set to a page size, in bytes, for which to return statistics. The arg parameter should be the size of the vminfo psize structure.

An additional parameter that will depend upon the command parameter.

### **Execution Environment**

The **kvmgetinfo** kernel service can be called from the process environment only.

#### **Return Values**

The following return values apply to all commands other than VMINFO\_GETPSIZES:

0 Indicates successful completion.

**ENOSYS** Indicates the *command* parameter is not valid (or not yet implemented).

**EINVAL** When VM PAGE INFO is the command, the adr field of the vm page info structure is an

invalid address.

arg

When VMINFO GETPSIZES is specified as the command, -1 is returned if the kvmgetinfo() kernel service is unsuccessful. Otherwise, the kvmgetinfo() kernel service returns a number of page sizes when the VMINFO\_GETPSIZES command is specified.

### Related Information

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# kwpar\_checkpoint\_status Kernel Service

# **Purpose**

Provides a method for kernel services to inform the system that an event has occurred within a workload partition (WPAR) that will deny or subsequently will re-allow a checkpoint of the WPAR.

# **Syntax**

#include <sys/wparid.h>

int kwpar\_checkpoint\_status (kcid, cmd, varp) cid t kcid; int cmd; void \* varp;

## **Parameters**

An integer command that informs the API what action to take on behalf of the caller. cmd kcid The WPAR ID where the command operation is to take place. A void pointer to different elements depending on the *cmd* parameter. varp

- If the cmd parameter is set to the WPAR CHECKPOINT TRY value, the varp parameter is a pointer to an integer variable containing the number of seconds that the caller is willing to wait before a blocking event is removed.
- If the cmd parameter is set to the WPAR\_CHECKPOINT\_DENY value, the varp parameter is a pointer to a null terminated character string that contains a user readable reason for posting the event.

The WPAR restart state is initially set when the WPAR is recreated on the arrival

## Cmd Types

The cmd parameter is supplied on input to the kwpar\_checkpoint\_status API and describes the type of action or event notification the caller is expecting. The following *cmd* types are supported:

WPAR_CHECKPOINT_DENY	The caller is experiencing an event within the WPAR identified by the <i>kcid</i>
	parameter that would deny a checkpoint operation. The caller must supply a
	pointer to a user readable character string in the varp parameter.
WPAR_CHECKPOINT_ALLOW	The caller is clearing a previous checkpoint denial operation. Deny and allow
	operations are cumulative and thus each denial operation must be matched with
	an allow operation before a checkpoint is finally re-allowed.
WPAR_CHECKPOINT_TRY	Used by the AIX® 5.1 checkpoint system itself. The caller supplies the <i>varp</i> pointer
	to an integer containing a "willing to wait" timeout in seconds before a checkpoint
	denial operation is cleared.
WPAR_CHECKPOINT_CLEAR	Used by the AIX® 5.1 checkpoint system itself. The caller has completed a
	checkpoint after a successful WPAR_TRY_CHKPNT operation.
WDAD DECTART CLEAR	Used by the AIX® 5.1 checkpoint system itself. The caller has completed a restart.
WPAR_RESTART_CLEAR	osed by the AIX 5.1 checkpoint system itself. The caller has completed a restart.

system.

# **Description**

The kwpar\_checkpoint\_status kernel service provides a mechanism for kernel services to inform or query the system about a checkpoint denial event. Kernel extensions that experience a temporary event which prevents a WPAR from being the target of a checkpoint operation, must use this API to deny and then to subsequently re-allow a checkpoint when the event clears. An example denial event might occur if a device open is in an un-serialized interim state that cannot handle a checkpoint operation.

## **Execution Environment**

The kwpar\_checkpoint\_status kernel service can be called from the process environment only.

### **Return Values**

Success. non-zero Failure.

### **Error Codes**

The **kwpar checkpoint status** service fails if one or more of the following errors occur:

**EINVAL** The caller has supplied a not valid *cmd* or other parameter. **ENOENT** No WPAR with the kcid ID is currently active in the system. **EBUSY** Either of the following situations can lead to the EBUSY error.

> WPAR is in a checkpoint or restart state. The caller is unsuccessful in a WPAR\_CHECKPOINT\_DENY operation.

· WPAR is in a state that cannot participate in a checkpoint. The caller is

unsuccessful in a WPAR\_CHECKPOINT\_TRY operation.

**ETIMEDOUT** The caller is waiting for a timeout period during a WPAR\_CHECKPOINT\_TRY

operation but the timer has expired.

#### **Related Information**

The WPAR CKPT QUERY (Checkpoint Query) Device Driver loctl Operation

# kwpar\_getname Kernel Service

# **Purpose**

Returns the workload partition name associated with the requested ID.

# **Syntax**

```
#include<sys/wparid.h>
#include<sys/xmem.h>
```

```
int kwpar_getname(kcid, buffer, length, adspace)
cid t kcid;
char * buffer;
size t length;
int adspace;
```

# **Description**

Get the name associated with the workload partition ID (kcid) and write it to the output buffer. The maximum number of bytes to write is limited by the length parameter. The length parameter cannot exceed MAXCORRALNAMELEN. The service writes to either user space or kernel space, depending on the value specified for the adspace parameter.

## **Parameters**

kcid Specifies the workload partition ID.

buffer Points to the buffer where the workload partition name is stored.

length Specifies the maximum number of bytes to return.

adspace Indicates in which part of memory the buffer parameter is located:

SYS ADSPACE

Indicates that the buffer parameter is in the kernel memory.

**USER ADSPACE** 

Indicates that the buffer parameter is in the application memory.

## **Execution Environment**

Process environment only.

### **Return Values**

The command completed successfully.

**EINVAL** Invalid WPAR ID or specified length is greater than MAXCORRALNAMELEN.

**EFAULT** Error during copyout to user space.

## **Related Information**

None.

# kwpar\_getrootpath Kernel Service

# **Purpose**

Returns the root path of the workload partition associated with the requested ID.

# **Syntax**

#include<sys/wparid.h>

```
int kwpar getrootpath(kcid, length, buffer)
cid t kcid;
size t * length;
char * buffer;
```

# **Description**

Get the root path of the workload partition associated with the kcid parameter and copy it to the output buffer. On entry, the value specified for the length parameter indicates the size of the output buffer. On return, the value specified for the length parameter, contains the size of the root path. If the value for the length parameter on entry is smaller than the actual path length, then ENOSPC is returned. Then, the length parameter is set to the actual length of the root path.

### **Parameters**

kcid Specifies the workload partition ID.

Specifies the maximum number of bytes to return. length

Points to the buffer where the workload partition root path will be stored. buffer

## **Execution Environment**

Process environment only.

## **Return Values**

0 The command completed successfully.

**EINVAL** Error indicating that buffer is NULL, length is NULL, or \*length is 0.

**ENOENT** Invalid WPAR ID specified for the kcid parameter.

**ENOSPC** Insufficient space in buffer to copy path.

## **Related Information**

None.

# kwpar\_isappwpar Kernel Service

# **Purpose**

Returns whether a workload partition is an application workload partition.

# **Syntax**

#include <sys/wparid.h>

int kwpar isappwpar(kcid) cid\_t kcid;

# Description

Checks whether the workload partition associated with the kcid is an application workload partition.

## **Parameters**

kcid Specifies the workload partition ID.

## **Execution Environment**

Process environment only.

#### **Return Values**

Workload partition is an application workload partition. 0 Workload partition is not an application workload partition. -1 Indicates that the command did not complete successfully.

## **Related Information**

None.

# kwpar\_r2vmap\_devno Kernel Service

# **Purpose**

Maps a real device number to the corresponding virtual device number for a given workload partition (WPAR).

## **Syntax**

#include <sys/wparid.h>

int kwpar\_r2vmap\_devno ( wparid, vdevno, rdevno)

cid t wparid; dev t rdevno; dev t \* vdevno;

#### **Parameters**

WPAR identifier. This parameter is required. wparid rdevno Real device number. This parameter is required.

vdevno Points to the data area that will contain the virtual device number. This parameter is passed

by reference. This parameter is optional.

# **Description**

The **kwpar r2vmap devno** kernel service provides the ability to translate a real device number, maintained in the kernel device switch table, to the corresponding virtual device number maintained in the user space. The caller must specify an existing WPAR identifier with the wparid parameter and a valid real device number with the rdevno parameter. The kwpar\_r2vmap\_devno kernel service writes the corresponding virtual device number to the data area pointed to by the *vdevno* parameter (if specified). If the vdevno parameter is not specified, the return code indicates whether a mapping exists for the given WPAR identifier and real device number.

A mapping for the specified virtual device number must exist for the kwpar v2rmap devno kernel service to succeed.

#### **Execution Environment**

The **kwpar\_r2vmap\_devno** kernel service can be called from the process environment only.

#### **Return Values**

Success. Failure. non-zero

#### **Error Codes**

The kwpar\_r2vmap\_devno service fails if one or more of the following errors occur:

**EINVAL** Either the *wparid* or *rdevno* argument is invalid.

**ENXIO** Unable to locate the WPAR device map associated with the given WPAR ID. **ESRCH** Unable to locate a mapping for the given real device number *rdevno*.

### **Related Information**

The kwpar v2rmap devno kernel service, kwpar regdevno kernel service, kwpar unregdevno kernel service.

# kwpar\_r2vmap\_pid Kernel Service

# **Purpose**

Maps a real process ID to the equivalent virtual process ID assigned within a workload partition.

# **Syntax**

```
#include <sys/wparid.h>
```

```
pid_t kwpar_r2vmap_pid ( kcidp, rpid)
cid_t * kcidp;
pid t rpid;
```

### **Parameters**

A pointer to a memory location where the workload partition (WPAR) ID associated with the kcidp

rpid parameter is returned.

rpid The real process ID on which to translate a real process ID to a virtual process ID.

# **Description**

The kwpar\_r2vmap\_pid kernel service provides a mapping from a real process ID to a virtual process ID assigned within the workload partition. In most instances, the real and virtual process IDs are the same except in cases where the Workload Partition Mobility is in effect or for certain system services such as the init command which always have different real and virtual process IDs.

Usually kernel services dealing with process IDs only accept real process IDs. However, in some instances it might be necessary for kernel extensions, which communicate with other WPAR services or with processes within the WPAR, to know and communicate with virtual process IDs.

#### **Execution Environment**

The kwpar\_r2vmap\_pid kernel service can be called from the process environment only.

## **Return Values**

If the **kwpar\_r2vmap\_pid** kernel service succeeds, it returns the virtual *pid\_t* value associated with the rpid value provided on input. If the kernel service fails or if there is no virtual process ID associated with the rpid value, the rpid value is returned.

## **Related Information**

The kwpar\_v2rmap\_pid kernel service.

# kwpar r2vmap tid Kernel Service

# **Purpose**

Maps a real thread ID to the equivalent virtual thread ID assigned within a workload partition.

# **Syntax**

```
#include <sys/wparid.h>
```

```
tid_t kwpar_r2vmap_tid ( kcidp, rtid)
cid_t * kcidp;
tid_t rtid;
```

#### **Parameters**

kcidp A pointer to a memory location where the WPAR ID associated with the rtid parameter is

returned.

rtid The real thread ID on which to translate a real process ID to a virtual process ID.

# **Description**

The kwpar\_r2vmap\_tid kernel service provides a mapping from a real thread ID to a virtual thread ID assigned within the workload partition. In most instances, the real and virtual thread IDs are the same except in cases where the Workload Partition Mobility is in effect.

Normally kernel services dealing with thread IDs accept only real thread IDs. However, in some instances it might be necessary for kernel extensions, which communicate with other WPAR services or with processes within the WPAR, to know and communicate with virtual thread IDs.

## **Execution Environment**

The **kwpar r2vmap tid** kernel service can be called from the process environment only.

### **Return Values**

If the kwpar\_r2vmap\_tid kernel service succeeds, it returns the virtual tid\_t value associated with the rtid value provided on input. If the kernel service fails or if there is no virtual process ID associated with the rtid value, the rtid value is returned.

### **Related Information**

The kwpar\_v2rmap\_tid kernel service.

# kwpar\_regdevno Kernel Service

# **Purpose**

Registers a virtual device number for a given workload partition (WPAR) by mapping it to a real device number in the device switch table.

# **Syntax**

#include <sys/wparid.h>

int kwpar\_regdevno ( wparid, vdevno, rdevno) cid\_t wparid; dev\_t vdevno; dev\_t \* rdevno;

#### **Parameters**

wparid WPAR ID. This parameter is required.

vdevno Virtual device number. This parameter is required.

Points to the data area that will contains the real device number. This parameter is passed rdevno

by reference. This parameter is required.

# **Description**

The **kwpar\_regdevno** kernel service provides the ability to register a virtual device number for a given WPAR by mapping it to a real device number in the device switch table. The kwpar\_regdevno kernel service performs the following steps:

- 1. Locates a free slot in the kernel device switch table and reserves it for the WPAR specified by the wparid parameter.
- 2. Creates a mapping between the virtual device number, which is specified by the vdevno parameter, to the real device number reserved in the previous step.

3. The newly reserved real device number is passed back to the caller through the *rdevno* parameter.

## **Execution Environment**

The kwpar\_regdevno kernel service can be called from the process environment only.

### **Return Values**

Success. non-zero Failure.

### **Error Codes**

The **kwpar regdevno** kernel service fails if one or more of the following errors occur:

**EINVAL** Either the *wparid* or *vdevno* argument is not valid.

**ENXIO** Unable to locate the WPAR device map associated with the given WPAR ID.

**ENOTEMPTY** The virtual device number vdevno is already mapped.

## **Related Information**

The kwpar r2vmap devno kernel service, kwpar v2rmap devno kernel service, kwpar unregdevno kernel service.

# kwpar\_reghook Kernel Service

# **Purpose**

Registers a function callback with workload partition (WPAR) kernel services. Callback functions are subsequently performed when specific WPAR conditions occur.

# **Syntax**

#include <sys/wparid.h>

regkey\_t kwpar\_reghook ( hooktype, hookp) int hooktype; void \* hookp;

#### **Parameters**

hooktype Identifies the form of the *hookp* pointer.

A pointer to a memory location that might contain function pointers or other structure hookp

elements that are interpreted depending on the supplied hooktype value.

### **Hook Types**

The hooktype parameter is supplied on input to the kwpar reghook return and describes the form of the second parameter. The supported hook types are as follows:

**WPAR\_NOTIFY\_HOOK** Identifies the form of the *hookp* parameter as being of type **wpar\_config\_hook\_t**.

The wpar config hook t structure contains the following fields:

On output from the kwpar reghook service, this field contains the current upper number of uint current\_hiwater

> WPARs that have become active on this boot instance of AIX® 5.1. WPAR IDs are allocated in numeric order. Kernel subsystems that want to size internal components according to the number of active WPARs must register a WPAR\_NOTIFY\_HOOK hook type and examine the current\_hiwater value for existing WPARs during registration. Future WPAR activation after hook registration calls the specified configp function within the wpar config hook t element. See the WPARSTART flags later in this section for a further description of the

WPAR activation.

wpar\_config\_func\_t

configp

On input, this field contains a pointer to a callback routine that is invoked by the WPAR kernel services during the activation and the deactivation of workload partitions within the

The syntax for the **wpar config func t** is as follows:

#include <sys/wpar.h>

typedef int \* wpar\_config\_func\_t ( flags, cid, corralp, unused)

int flaas: cid t cid; struct corral \* corralp; void \* unused;

The parameters are as follows:

Information regarding the type of condition that is occurring within the workload partition. flags

The ID for the workload partition experiencing the condition. cid

A pointer to a kernel copy of the **corral** structure that might have been supplied from the corralp

user space at the start of the condition processing.

unused Currently unused and must be set to NULL. It might be expanded to contain additional

information in later revisions of this API.

The *flags* parameter can have the following potential values:

**WPARSTART** Signifies that the WPAR is undergoing activation. The callout to registered routines occurs

> before any other kernel subsystem processing occurs. Kernel components registering and desiring to see the WPAR activation are informed that a new WPAR with the cid parameter

set is going to enter the AIX® 5.1 kernel system.

Signifies that the WPAR has undergone deactivation. The callout to registered routines **WPARSTOP** 

> occurs after all other kernel subsystem processing occurs. Kernel components registering and desiring to see the WPAR deactivation are informed that an existing WPAR with the cid

parameter set has now left the AIX® 5.1 kernel system.

# **Description**

The kwpar\_reghook kernel service provides a mechanism for other kernel services to register callbacks and retrieve information when certain workload partition conditions occur.

#### **Execution Environment**

The **kwpar\_reghook** kernel service can be called from the process environment only.

#### Return Values

If the kwpar\_reghook kernel service is successful, it returns a registration key that can subsequently be used with the kwpar unreghook kernel service. If the kernel service fails, it returns a numeric value equivalent to the BADREGKEY definition found in the wparid.h file.

## **Error Codes**

The **kwpar\_reghook** kernel service fails if no space remains to record additional registration hook.

#### **Related Information**

The kwpar unreghook kernel service.

# kwpar\_unregdevno Kernel Service

# **Purpose**

Unregisters the mapping associated with a real device number for a given workload partition (WPAR).

# **Syntax**

#include <sys/wparid.h>

int kwpar\_unregdevno ( wparid, rdevno) cid\_t wparid; dev\_t rdevno;

### **Parameters**

WPAR identifier. This parameter is required. wparid rdevno Real device number. This parameter is required.

# **Description**

The kwpar\_unregdevno kernel service provides the ability to unregister the mapping associated with a real device number for a given WPAR. The **kwpar unregdevno** kernel service will perform the following steps:

- 1. Deletes the virtual-to-real mapping associated with the real device number specified by the *rdevno* parameter for the WPAR specified by the wparid parameter.
- 2. Releases the reserve associated with the real device number specified by the *rdevno* parameter.

## **Execution Environment**

The kwpar\_unregdevno kernel service can be called from the process environment only.

#### **Return Values**

Success. non-zero Failure.

#### **Error Codes**

The **kwpar unregdevno** kernel service fails if one or more of the following errors occur:

**EINVAL** Either the wparid or rdevno argument is not valid.

**ENXIO** Unable to locate the WPAR device map associated with the given WPAR ID. **ESRCH** Unable to locate the mapping for the given real device number rdevno.

## **Related Information**

The kwpar\_r2vmap\_devno kernel service.

The kwpar\_v2rmap\_devno kernel service.

The kwpar\_regdevno kernel service.

# kwpar\_unreghook Kernel Service

## **Purpose**

Removes a previously registered workload partition (WPAR) callback hook.

# **Syntax**

#include <sys/wparid.h>

int kwpar\_unreghook ( key) regkey\_t key;

#### **Parameters**

key The registration key of the hook that the caller wants to un-register. This key is equivalent to

the key returned from a hook registration with the kwpar\_reghook kernel service.

# **Description**

The kwpar\_unreghook kernel service informs workload partitions that the caller no longer wants to receive callouts for WPAR conditions.

## **Execution Environment**

The kwpar\_unreghook kernel service can be called from the process environment only.

## **Return Values**

Success. non-zero Failure.

## **Error Codes**

The **kwpar\_unreghook** service fails if one or more of the following errors occur:

**EINVAL** Not a valid registration key.

**EPERM** Not allowed to un-register this key.

## **Related Information**

The kwpar\_reghook kernel service.

# kwpar\_v2rmap\_devno Kernel Service

# **Purpose**

Maps a virtual device number to the corresponding real device number in the device switch table for a given workload partition (WPAR).

# **Syntax**

#include <sys/wparid.h>

int kwpar\_v2rmap\_devno ( wparid, vdevno, rdevno) cid t wparid; dev\_t vdevno; dev\_t \* rdevno;

### **Parameters**

wparid WPAR identifier. This parameter is required. Virtual device number. This parameter is required. vdevno

rdevno Points to the data area that will contain the real device number. This parameter is passed

by reference. This parameter is optional.

# Description

The kwpar\_v2rmap\_devno kernel service provides the ability to translate a virtual device number maintained in user space to the corresponding real device number maintained in the kernel device switch table. The caller must specify an existing WPAR identifier with the wparid parameter and a valid virtual device number with the vdevno parameter. The kwpar v2rmap devno kernel service will write the corresponding real device number to the data area pointed to by the rdevno parameter if it is specified. If the rdevno parameter is not specified, the return code will indicate whether a mapping exists for the given WPAR identifier and virtual device number.

A mapping for the specified virtual device number must exist for the kwpar\_v2rmap\_devno kernel service to succeed.

## **Execution Environment**

The kwpar v2rmap devno kernel service can be called from the process environment only.

#### **Return Values**

Success. non-zero Failure.

#### **Error Codes**

The kwpar\_v2rmap\_devno service fails if one or more of the following errors occur:

**EINVAL** Either the wparid or vdevno argument is not valid.

**ENXIO** Unable to locate the WPAR device map associated with the given WPAR id.

**ENODEV** Unable to locate the mapping for the given virtual device number.

## **Related Information**

The kwpar\_r2vmap\_devno kernel service.

The **kwpar regdevno** kernel service.

The kwpar\_unregdevno kernel service.

# kwpar\_v2rmap\_pid Kernel Service

# **Purpose**

Maps a virtual process ID associated with a process within a workload partition to the equivalent real process ID.

# **Syntax**

#include <sys/wparid.h>

pid\_t kwpar\_v2rmap\_pid ( kcid, vpid) cid\_t kcid; pid\_t vpid;

### **Parameters**

kcid The workload partition (WPAR) ID associated with the vpid parameter. Equivalent virtual

process IDs can be in use across different processes in different WPARs. Thus the caller

must provide the WPAR ID for which a virtual to real mapping is to occur.

The virtual process ID on which to perform a virtual to real mapping. vpid

# **Description**

The kwpar\_v2rmap\_pid kernel service provides a mapping from a virtual process ID associated with a process in a workload partition to the equivalent real process ID. In most instances, both the real and virtual process IDs are the same, except in cases where the Workload Partition Mobility is in effect.

Normally, kernel services dealing with process IDs accept only real thread IDs. In some instances where a kernel extension is communicating with other WPAR services or with processes within the WPAR, a mapping from virtual to real process IDs might be needed.

#### **Execution Environment**

The kwpar\_v2rmap\_pid kernel service can be called from the process environment only.

#### **Return Values**

If the **kwpar\_v2rmap\_pid** kernel service succeeds, it returns the real *pid\_t* value associated with the *vpid* value provided on input. If the kernel service fails, or if there is no real thread ID associated with the *vpid* value, then the *vpid* value is returned.

## **Related Information**

The kwpar\_r2vmap\_pid kernel service.

# kwpar\_v2rmap\_tid Kernel Service

# **Purpose**

Maps a virtual thread ID associated with a thread within a workload partition to the equivalent real thread ID.

# **Syntax**

```
#include <sys/wparid.h>
tid_t kwpar_v2rmap_tid ( kcid, vtid)
cid_t kcid;
tid_t vtid;
```

## **Parameters**

kcid The workload partition (WPAR) ID associated with the vtid parameter. Equivalent virtual

thread IDs can be in use across different threads in different WPARs. Thus the caller must

provide the WPAR ID for which a virtual to real mapping is to occur.

vtid The virtual thread ID on which to perform a virtual to real mapping.

# **Description**

The kwpar\_v2rmap\_tid kernel service provides a mapping from a virtual thread ID associated with a thread in a workload partition to the equivalent real thread ID. In most instances, both the real and virtual thread IDs are the same, except in cases where the Workload Partition Mobility is in effect. Normally, kernel services dealing with thread IDs accept only real thread IDs. In some instances where a kernel extension is communicating with other WPAR services or with processes within the WPAR, a mapping from virtual to real thread IDs might be needed.

#### **Execution Environment**

The kwpar v2rmap tid kernel service can be called from the process environment only.

### **Return Values**

If the kwpar v2rmap tid kernel service succeeds, it returns the real tid t value associated with the vtid value provided on input. If the kernel service fails, or if there is no real thread ID associated with the vtid value then the vtid value is returned.

#### **Related Information**

The kwpar\_r2vmap\_tid kernel service.

# limit\_sigs or sigsetmask Kernel Service

# **Purpose**

Changes the signal mask for the calling kernel thread.

# **Syntax**

```
#include <sys/encap.h>
void limit_sigs (
siglist,
```

```
old mask)
sigset t *siglist;
sigset_t *old_mask;
void sigsetmask ( old mask)
sigset t *old mask;
```

## **Parameters**

sialist Specifies the signal set to deliver. Points to the old signal set. old\_mask

# **Description**

The limit\_sigs kernel service changes the signal mask for the calling kernel thread such that only the signals specified by the siglist parameter will be delivered, unless they are currently being blocked or ignored.

The old signal mask is returned via the *old\_mask* parameter. If the *siglist* parameter is **NULL**, the signal mask is not changed; it can be used for getting the current signal mask.

The **sigsetmask** kernel service should be used to restore the set of blocked signals for the calling thread. The typical usage of these services is the following:

```
sigset_t allowed = limited set of signals
sigset_t old;
/* limits the set of delivered signals */
limit sigs (&allowed, &old);
   /* do something with a limited set of delivered signals */
/* restore the original set */
sigsetmask (&old);
```

## **Execution Environment**

The limit\_sigs and sigsetmask kernel services can be called from the process environment only.

#### **Return Values**

The **limit sigs** and **sigsetmask** kernel services have no return values.

#### **Related Information**

The kthread\_kill kernel service.

# livedump Kernel Service

# Purpose

Starts a live dump.

# **Syntax**

```
#include <sys/livedump.h>
kerrno t livedump (parms)
ldmp_parms_t *parms;
```

### **Parameters**

parms

Points to an item of Idmp\_parms\_t type.

# **Description**

The livedump kernel service initiates a live dump. It can be called from either the kernel or a kernel extension. Storage associated with the dump is not entirely freed until the dump has been written to disk, or the livedump kernel service returns an error indicating the dump was not taken.

#### **Execution Environment**

The livedump kernel service can be called from either the process or interrupt environment. Only a serialized, synchronous dump can be started from the interrupt level, and the dump is limited to one pass.

## **Return Values**

Indicates a successful completion.

EINVAL\_RAS\_LIVEDUMP\_PARM Indicates that one or more parameters are not valid.

EFAULT RAS LIVEDUMP\_PARM Indicates that a memory fault occurs.

EINVAL\_RAS\_LIVEDUMP\_COMP Indicates one or more components are not valid. EINVAL RAS LIVEDUMP NOCOMPS Indicates that no valid components were given.

### **Related Information**

The **Idmp setupparms** kernel service, **dmp compspec** kernel service, **dmp eaddr** kernel service, dmp\_context kernel service, dmp\_tid kernel service, dmp\_pid kernel service, dmp\_errbuf kernel service, dmp\_mtrc kernel service, dmp\_systrace kernel service, dmp\_ct kernel service, and dmp kernext kernel service.

# lock alloc Kernel Service

# **Purpose**

Allocates system memory for a simple or complex lock.

# **Syntax**

```
#include <sys/lock def.h>
#include <sys/lock_alloc.h>
void lock alloc ( lock addr, flags, class, occurrence)
void *lock addr;
int flags;
short class;
short occurrence;
```

#### **Parameters**

lock\_addr Specifies a valid simple or complex lock address. flags Specifies whether the memory allocated is to be pinned or pageable. Set this parameter as follows:

#### LOCK\_ALLOC\_PIN

Allocate pinned memory; use if it is not permissible to take a page fault while calling a locking kernel service for this lock.

#### LOCK\_ALLOC\_PAGED

Allocate pageable memory; use if it is permissible to take a page fault while calling a locking kernel service for this lock.

class Specifies the family which the lock belongs to.

Identifies the instance of the lock within the family. If only one instance of the lock is defined, this occurrence

parameter should be set to -1.

# **Description**

The **lock alloc** kernel service allocates system memory for a simple or complex lock. The **lock alloc** kernel service must be called for each simple or complex before the lock is initialized and used. The memory allocated is for internal lock instrumentation use, and is not returned to the caller; no memory is allocated if instrumentation is not used.

### **Execution Environment**

The lock\_alloc kernel service can be called from the process environment only.

### Return Values

The lock alloc kernel service has no return values.

### Related Information

The lock free kernel service, lock init kernel service, simple lock init kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

# lock\_clear\_recursive Kernel Service

# **Purpose**

Prevents a complex lock from being acquired recursively.

# **Syntax**

```
#include <sys/lock def.h>
```

```
void lock_clear_recursive ( lock addr)
complex_lock_t lock addr;
```

#### **Parameter**

lock\_addr Specifies the address of the lock word which is no longer to be acquired recursively.

# **Description**

The lock\_clear\_recursive kernel service prevents the specified complex lock from being acquired recursively. The lock must have been made recursive with the lock set recursive kernel service. The calling thread must hold the specified complex lock in write-exclusive mode.

## **Execution Environment**

The lock\_clear\_recursive kernel service can be called from the process environment only.

### **Return Values**

The lock clear recursive kernel service has no return values.

## **Related Information**

The lock\_init kernel service, lock\_done kernel service, lock\_read kernel service, lock\_read\_to\_write kernel service, lock write kernel service, lock set recursive kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

## lock done Kernel Service

# Purpose

Unlocks a complex lock.

# **Syntax**

```
#include <sys/lock_def.h>
void lock done ( lock addr)
complex lock t lock addr;
```

### **Parameter**

lock\_addr

Specifies the address of the lock word to unlock.

# **Description**

The **lock done** kernel services unlocks a complex lock. The calling kernel thread must hold the lock either in shared-read mode or exclusive-write mode. If one or more kernel threads are waiting to acquire the lock in exclusive-write mode, one of these kernel threads (the one with the highest priority) is made runnable and may compete for the lock. Otherwise, any kernel threads which are waiting to acquire the lock in shared-read mode are made runnable. If there was at least one kernel thread waiting for the lock, the priority of the calling kernel thread is recomputed.

If the lock is held recursively, it is not actually released until the lock\_done kernel service has been called once for each time that the lock was locked.

#### **Execution Environment**

The **lock\_done** kernel service can be called from the process environment only.

#### Return Values

The lock done kernel service has no return values.

#### **Related Information**

The lock\_alloc kernel service, lock\_free kernel service, lock\_init kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

# lock\_free Kernel Service

# **Purpose**

Frees the memory of a simple or complex lock.

# **Syntax**

```
#include <sys/lock def.h>
#include <sys/lock alloc.h>
void lock free ( lock addr)
void *lock addr;
```

## **Parameter**

lock addr

Specifies the address of the lock word whose memory is to be freed.

# **Description**

The lock\_free kernel service frees the memory of a simple or complex lock. The memory freed is the internal operating system memory which was allocated with the lock\_alloc kernel service.

Note: It is only necessary to call the lock\_free kernel service when the memory that the corresponding lock was protecting is released. For example, if you allocate memory for an i-node which is to be protected by a lock, you must allocate and initialize the lock before using it. The memory may be used with several i-nodes, each taken from, and returned to, the free i-node pool; the lock\_init kernel service must be called each time this is done. The lock free kernel service must be called when the memory allocated for the inode is finally freed.

## **Execution Environment**

The lock\_free kernel service can be called from the process environment only.

#### **Return Values**

The lock free kernel service has no return values.

### **Related Information**

The lock alloc kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

## lock\_init Kernel Service

# **Purpose**

Initializes a complex lock.

# **Syntax**

```
#include <sys/lock def.h>
void lock init ( lock addr, can sleep)
complex_lock_t lock addr;
boolean_t can sleep;
```

### **Parameters**

lock\_addr Specifies the address of the lock word.

This parameter is ignored. can\_sleep

# **Description**

The lock init kernel service initializes the specified complex lock. This kernel service must be called for each complex lock before the lock is used. The complex lock must previously have been allocated with the lock\_alloc kernel service. The can\_sleep parameter is included for compatibility with OSF/1 1.1, but is ignored. Using a value of TRUE for this parameter will maintain OSF/1 1.1 semantics.

### **Execution Environment**

The lock\_init kernel service can be called from the process environment only.

### **Return Values**

The lock init kernel service has no return values.

## **Related Information**

The lock\_alloc kernel service, lock\_free kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

## lock islocked Kernel Service

# **Purpose**

Tests whether a complex lock is locked.

# **Syntax**

```
#include <sys/lock def.h>
int lock_islocked ( lock addr)
complex_lock_t lock addr;
```

#### **Parameter**

Specifies the address of the lock word to test. lock\_addr

# **Description**

The lock islocked kernel service determines whether the specified complex lock is free, or is locked in either shared-read or exclusive-write mode.

#### **Execution Environment**

The **lock** islocked kernel service can be called from the process environment only.

#### **Return Values**

TRUE Indicates that the lock was locked. **FALSE** Indicates that the lock was free.

## **Related Information**

The lock init kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

## lockl Kernel Service

# **Purpose**

Locks a conventional process lock.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/lockl.h>
int lockl ( lock word, flags)
lock t *lock word;
int flags;
```

#### **Parameters**

lock \_word flags

Specifies the address of the lock word.

Specifies the flags that control waiting for a lock. The flags parameter is used to control how signals affect waiting for a lock. The four flags are:

#### LOCK\_NDELAY

Controls whether the caller waits for the lock. Setting the flag causes the request to be terminated. The lock is assigned to the caller. Not setting the flag causes the caller to wait until the lock is not owned by another process before the lock is assigned to the caller.

#### LOCK\_SHORT

Prevents signals from terminating the wait for the lock. LOCK\_SHORT is the default flag for the lock! Kernel Service. This flag causes non-preemptive sleep.

#### LOCK\_SIGRET

Causes the wait for the lock to be terminated by an unmasked signal.

#### LOCK\_SIGWAKE

Causes the wait for the lock to be terminated by an unmasked signal and control transferred to the return from the last operation by the **setjmpx** kernel service.

Note: The LOCK\_SIGRET flag overrides the LOCK\_SIGWAKE flag.

# **Description**

Note: The lockl kernel service is provided for compatibility only and should not be used in new code, which should instead use simple locks or complex locks.

The lockl kernel service locks a conventional lock

The lock word can be located in shared memory. It must be in the process's address space when the lockl or unlockl services are called. The kernel accesses the lock word only while executing under the caller's process.

The lock word parameter is typically part of the data structure that describes the resource managed by the lock. This parameter must be initialized to the LOCK AVAIL value before the first call to the lockl service. Only the lockl and unlockl services can alter this parameter while the lock is in use.

The lockl service is nestable. The caller should use the LOCK\_SUCC value for determining when to call the **unlock!** service to unlock the conventional lock.

The lockl service temporarily assigns the owner the process priority of the most favored waiter for the lock.

A process must release all locks before terminating or leaving kernel mode. Signals are not delivered to kernel processes while those processes own any lock. "Understanding System Call Execution" in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts discusses how system calls can use the lockl service when accessing global data.

### **Execution Environment**

The lockl kernel service can be called from the process environment only.

## **Return Values**

LOCK SUCC Indicates that the process does not already own the lock or the lock is not owned by another

process when the *flags* parameter is set to **LOCK\_NDELAY**.

LOCK NEST Indicates that the process already owns the lock or the lock is not owned by another process when

the flags parameter is set to LOCK\_NDELAY.

LOCK FAIL Indicates that the lock is owned by another process when the flags parameter is set to

LOCK\_NDELAY.

LOCK\_SIG Indicates that the wait is terminated by a signal when the flags parameter is set to LOCK SIGRET.

### **Related Information**

The unlockl kernel service.

Understanding Locking in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

# lock mine Kernel Service

# **Purpose**

Checks whether a simple or complex lock is owned by the caller.

# **Syntax**

#include <sys/lock\_def.h>

boolean\_t lock\_mine ( lock\_addr) void \*lock addr;

#### **Parameter**

lock addr Specifies the address of the lock word to check.

# **Description**

The **lock mine** kernel service checks whether the specified simple or complex lock is owned by the calling kernel thread. Because a complex lock held in shared-read mode has no owner, the service returns FALSE in this case. This kernel service is provided to assist with debugging.

### **Execution Environment**

The lock\_mine kernel service can be called from the process environment only.

### **Return Values**

TRUE Indicates that the calling kernel thread owns the lock.

**FALSE** Indicates that the calling kernel thread does not own the lock, or that a complex lock is held in shared-read

### **Related Information**

The lock init kernel service, lock islocked kernel service, lock read kernel service, lock write kernel service, **simple\_lock** kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

# lock read or lock try read Kernel Service

## Purpose

Locks a complex lock in shared-read mode.

# **Syntax**

```
#include <sys/lock def.h>
void lock read ( lock addr)
complex lock t lock addr;
boolean_t lock_try_read ( lock_addr)
complex lock t lock addr;
```

#### **Parameter**

lock addr Specifies the address of the lock word to lock.

# **Description**

The lock read kernel service locks the specified complex lock in shared-read mode; it blocks if the lock is locked in exclusive-write mode. The lock must previously have been initialized with the lock init kernel service. The lock read kernel service has no return values.

The lock\_try\_read kernel service tries to lock the specified complex lock in shared-read mode; it returns immediately if the lock is locked in exclusive-write mode, otherwise it locks the lock in shared-read mode. The lock must previously have been initialized with the lock\_init kernel service.

### **Execution Environment**

The lock\_read and lock\_try\_read kernel services can be called from the process environment only.

## **Return Values**

The **lock\_try\_read** kernel service has the following return values:

TRUE Indicates that the lock was successfully acquired in shared-read mode.

FALSE Indicates that the lock was not acquired.

#### **Related Information**

The lock init kernel service, lock islocked kernel service, lock done kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

# lock read to write or lock try read to write Kernel Service

# **Purpose**

Upgrades a complex lock from shared-read mode to exclusive-write mode.

# **Syntax**

```
#include <sys/lock def.h>
boolean_t lock_read_to_write ( lock_addr)
complex lock t lock addr;
boolean_t lock_try_read_to_write ( lock addr)
complex_lock_t lock addr;
```

### **Parameter**

lock addr

Specifies the address of the lock word to be converted from read-shared to write-exclusive mode.

# **Description**

The lock\_read\_to\_write and lock\_try\_read\_to\_write kernel services try to upgrade the specified complex lock from shared-read mode to exclusive-write mode. The lock is successfully upgraded if no other thread has already requested write-exclusive access for this lock. If the lock cannot be upgraded, it is no longer held on return from the lock\_read\_to\_write kernel service; it is still held in shared-read mode on return from the lock\_try\_read\_to\_write kernel service.

The calling kernel thread must hold the lock in shared-read mode.

## **Execution Environment**

The lock read to write and lock try read to write kernel services can be called from the process environment only.

#### **Return Values**

The following only apply to lock read to write:

**TRUE** Indicates that the lock was not upgraded and is no longer held.

**FALSE** Indicates that the lock was successfully upgraded to exclusive-write mode. The following only apply to **lock\_try\_read\_to\_write**:

TRUE Indicates that the lock was successfully upgraded to exclusive-write mode.

**FALSE** Indicates that the lock was not upgraded and is held in read mode.

#### **Related Information**

The lock\_init kernel service, lock\_islocked kernel service, lock\_done kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

## lock set recursive Kernel Service

# **Purpose**

Prepares a complex lock for recursive use.

# **Syntax**

```
#include <sys/lock def.h>
void lock_set_recursive ( lock addr)
complex_lock_t lock addr;
```

### **Parameter**

lock\_addr

Specifies the address of the lock word to be prepared for recursive use.

# **Description**

The lock\_set\_recursive kernel service prepares the specified complex lock for recursive use. A complex lock cannot be nested until the lock\_set\_recursive kernel service is called for it. The calling kernel thread must hold the specified complex lock in write-exclusive mode.

When a complex lock is used recursively, the lock done kernel service must be called once for each time that the thread is locked in order to unlock the lock.

Only the kernel thread which calls the lock set recursive kernel service for a lock may acquire that lock recursively.

#### **Execution Environment**

The **lock set recursive** kernel service can be called from process environment only.

## **Return Values**

The lock set recursive kernel service has no return values.

#### Related Information

The lock\_init kernel service, lock\_done kernel service, lock\_write kernel service, lock\_clear\_recursive kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

# lock\_write or lock\_try\_write Kernel Service

# **Purpose**

Locks a complex lock in exclusive-write mode.

# **Syntax**

```
#include <sys/lock def.h>
void lock_write ( lock addr)
complex_lock_t lock addr;
boolean t lock try write ( lock addr)
complex_lock_t lock addr;
```

### **Parameter**

lock\_addr

Specifies the address of the lock word to lock.

# **Description**

The lock\_write kernel service locks the specified complex lock in exclusive-write mode; it blocks if the lock is busy. The lock must have been previously initialized with the lock\_init kernel service. The lock\_write kernel service has no return values.

The lock try write kernel service tries to lock the specified complex lock in exclusive-write mode; it returns immediately without blocking if the lock is busy. The lock must have been previously initialized with the lock init kernel service.

### **Execution Environment**

The lock write and lock try write kernel services can be called from the process environment only.

## **Return Values**

The lock\_try\_write kernel service has the following parameters:

TRUE Indicates that the lock was successfully acquired.

FALSE Indicates that the lock was not acquired.

### **Related Information**

The lock init kernel service, lock islocked kernel service, lock done kernel service, lock read to write kernel service, lock try read to write kernel service, lock write to read kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

# lock write to read Kernel Service

# **Purpose**

Downgrades a complex lock from exclusive-write mode to shared-read mode.

## **Syntax**

```
#include <sys/lock_def.h>
void lock write to read ( lock addr)
complex lock t lock addr;
```

### **Parameter**

lock\_addr

Specifies the address of the lock word to be downgraded from exclusive-write to shared-read mode.

# **Description**

The lock\_write\_to\_read kernel service downgrades the specified complex lock from exclusive-write mode to shared-read mode. The calling kernel thread must hold the lock in exclusive-write mode.

Once the lock has been downgraded to shared-read mode, other kernel threads will also be able to acquire it in shared-read mode.

### **Execution Environment**

The lock write\_to\_read kernel service can be called from the process environment only.

## **Return Values**

The lock write to read kernel service has no return values.

## **Related Information**

The lock init kernel service, lock islocked kernel service, lock done kernel service, lock read to write kernel service, lock try read to write kernel service, lock try write kernel service, lock write kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

# loifp Kernel Service

# **Purpose**

Returns the address of the software loopback interface structure.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
struct ifnet *loifp ()
```

# **Description**

The loifp kernel service returns the address of the ifnet structure associated with the software loopback interface. The interface address can be used to examine the interface flags. This address can also be used to determine whether the looutput kernel service can be called to send a packet through the loopback interface.

## **Execution Environment**

The **loifp** kernel service can be called from either the process or interrupt environment.

### **Return Values**

The loifp service returns the address of the ifnet structure describing the software loopback interface.

## **Related Information**

The looutput kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# longjmpx Kernel Service

# **Purpose**

Allows exception handling by causing execution to resume at the most recently saved context.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int longjmpx ( ret val)
int ret val;
```

#### **Parameters**

ret\_val

Specifies the return value to be supplied on the return from the setimpx kernel service for the resumed context. This value normally indicates the type of exception that has occurred.

# **Description**

The longjmpx kernel service causes the normal execution flow to be modified so that execution resumes at the most recently saved context. The kernel mode lock is reacquired if it is necessary. The interrupt priority level is reset to that of the saved context.

The longimpx service internally calls the clrimpx service to remove the jump buffer specified by the jump\_buffer parameter from the list of contexts to be resumed. The longjmpx service always returns a nonzero value when returning to the restored context. Therefore, if the value of the ret val parameter is 0, the longimpx service returns an EINTR value to the restored context.

If there is no saved context to resume, the system crashes.

## **Execution Environment**

The **longimpx** kernel service can be called from either the process or interrupt environment.

## **Return Values**

A successful call to the longimpx service does not return to the caller. Instead, it causes execution to resume at the return from a previous **setjmpx** call with the return value of the *ret\_val* parameter.

### **Related Information**

The **cirimpx** kernel service, **setimpx** kernel service.

Understanding Exception Handling in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## lookupvp, lookupname, lookupname cur Kernel Services

## **Purpose**

Retrieves the v-node that corresponds to the named path.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/uio.h>
int lookupvp ( namep, flags, compvpp, crp)
char *namep;
int flags;
struct vnode **compvpp;
struct ucred *crp;
int lookupname ( namep, seg, flags, dirvpp, compvpp, crp)
char *namep;
int seg;
int flags;
struct vnode **dirvpp;
struct vnode **compvpp;
struct cred *crp;
int lookupname_cur ( namep, seg, flags, dirvpp, compvpp, curdvp, crp)
char *namep;
int seg;
int flags;
struct vnode **dirvpp;
struct vnode **compvpp;
struct vnode **curdvp;
struct cred *crp;
```

#### **Parameters**

Points to the cred structure. This structure contains data that the file system can use to validate crp

access permission.

namep Points to a character string path name. flags Specifies lookup directives, including these six flags:

> L\_LOC The path-name resolution must not cross a mount point into another file system implementation.

#### L NOFOLLOW

If the final component of the path name resolves to a symbolic link, the link is not to be

#### L NOXMOUNT

If the final component of the path name resolves to a mounted-over object, the mounted-over object, rather than the root of the next virtual file system, is to be returned.

**L\_CRT** The object is to be created.

**L\_DEL** The object is to be deleted.

L EROFS

An error is to be returned if the object resides in a read-only file system.

Specifies whether the namep buffer is in user space (UIO\_USERSPACE) or kernel space seg

(UIO\_SYSSPACE).

Points to the location where the vnode pointer for the named object is to be returned to the calling compvpp

Points to the location where the vnode pointer for the directory containing the named object is to be dirvpp

returned.

curdvp Points to the vnode for a current directory to be used instead of u\_cdir.

## **Description**

The **lookupvp** kernel service provides translation of the path name provided by the *namep* parameter into a virtual file system node. The lookupvp service provides a flexible interface to path-name resolution by regarding the flags parameter values as directives to the lookup process. The lookup process is a cooperative effort between the logical file system and underlying virtual file systems (VFS). Several v-node and VFS operations are employed to:

- Look up individual name components
- Read symbolic links
- Cross mount points

The lookupvp kernel service determines the process's current and root directories by consulting the u cdir and u rdir fields in the u structure. Information about the virtual file system and file system installation for transient v-nodes is obtained from each name component's vfs or qfs structure. The **lookupvp** kernel service assumes that the named path is in kernel address space.

The lookupname kernel service provides the same service as the lookupvp kernel service, but allows the caller to specify whether the path name is in kernel or user space. It also provides the ability to retrieve the vnode for the directory containing the named object. The lookupname\_cur kernel service further extends the interface by allowing the lookup to proceed relative to the given curdvp directory.

The vnodes returned by the lookup services are held. The calling routine is responsible for releasing the hold by calling the **vnop\_rele** entry point when it completes its operation.

### **Execution Environment**

The **lookup** kernel services can be called from the process environment only.

### **Return Values**

Indicates a successful operation.

Indicates an error. This number is defined in the /usr/include/sys/errno.h file. errno

### **Related Information**

Virtual File System Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

Virtual File System (VFS) Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# **looutput Kernel Service**

## **Purpose**

Sends data through a software loopback interface.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int looutput ( ifp, m\theta, dst)
struct ifnet *ifp;
struct mbuf *mθ;
struct sockaddr *dst;
```

## **Parameters**

ifp Specifies the address of an ifnet structure describing the software loopback interface.

Specifies an mbuf chain containing output data. m0

Specifies the address of a sockaddr structure that specifies the destination for the data. dst

# **Description**

The **looutput** kernel service sends data through a software loopback interface. The data in the m0 parameter is passed to the input handler of the protocol specified by the dst parameter.

#### **Execution Environment**

The looutput kernel service can be called from either the process or interrupt environment.

### **Return Values**

Indicates that the data was successfully sent. **ENOBUFS** Indicates that resource allocation failed.

**EAFNOSUPPORT** Indicates that the address family specified by the dst parameter is not supported.

#### **Related Information**

The **loifp** kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## **Itpin Kernel Service**

## **Purpose**

Pins the address range in the system (kernel) space and frees the page space for the associated pages.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pin.h>
int ltpin (addr, length)
caddr t addr;
         length;
int
```

### **Parameters**

addr Specifies the address of the first byte to pin. length Specifies the number of bytes to pin.

## **Description**

The **Itpin** (long term pin) kernel service pins the real memory pages touched by the address range specified by the addr and length parameters in the system (kernel) address space. It pins the real-memory pages to ensure that page faults do not occur for memory references in this address range. The **Itpin** kernel service increments the long-term pin count for each real-memory page. While either the long-term or short-term pin count is nonzero, the page cannot be paged out of real memory.

The **Itpin** kernel service pins either the entire address range or none of it. Only a limited number of pages are pinned in the system. If there are not enough unpinned pages in the system, the Itpin kernel service returns an error code. The **Itpin** kernel service is not a published interface.

Note: The operating system pins only whole pages at a time. Therfore, if the requested range is not aligned on a page boundary, then memory outside this range is also pinned.

The **Itpin** kernel service can only be called for addresses within the system (kernel) address space.

### **Return Values**

Indicates successful completion.

**EINVAL** Indicates that the *length* parameter has a negative value. Otherwise, the area of memory beginning at

the address of the first byte to pin (the addr parameter) and extending for the number of bytes specified

by the *length* parameter is not defined.

**EIO** Indicates that a permanent I/O error occurred while referencing data.

**ENOMEM** Indicates that the pin kernel service was unable to pin due to insufficient real memory or exceeding the

system-wide pin count.

**ENOSPC** Indicates insufficient file system or paging space.

#### **Related Information**

The Itunpin kernel service.

## **Itunpin Kernel Service**

## **Purpose**

Unpins the address range in system (kernel) address space and reallocates paging space for the specified region.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pin.h>
int ltunpin (addr, length)
caddr_t addr;
int length;
```

### **Parameters**

addr Specifies the address of the first byte to unpin.

length Specifies the number of bytes to unpin.

## **Description**

The **Itunpin** kernel service decreases the long-term pin count of each page in the address range. When the long-term pin count becomes 0, the backing storage (paging space) for the memory region is allocated and assigned to the pages. When both the long-term and short-term pin counts are 0, the page is no longer pinned and the **Itunpin** kernel service will assert. If allocating backing pages would put the system below the low paging space threshold, the call waits until paging space becomes available.

The **Itunpin** kernel service can only be called with addresses in the system (kernel) address space from the process environment.

## **Return Values**

0 Indicates successful completion.

**EINVAL** Indicates that the *length* parameter is a negative value.

**EIO** Indicates that a permanent I/O error occurred while referencing data.

### **Related Information**

The Itpin kernel service.

# m\_adj Kernel Service

# **Purpose**

Adjusts the size of an mbuf chain.

# Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>

void m_adj ( m, diff)
struct mbuf *m;
int diff;
```

### **Parameters**

m Specifies the **mbuf** chain to be adjusted. diff Specifies the number of bytes to be removed.

## **Description**

The **m** adj kernel service adjusts the size of an **mbuf** chain by the number of bytes specified by the diff parameter. If the number specified by the diff parameter is nonnegative, the bytes are removed from the front of the chain. If this number is negative, the alteration is done from back to front.

### **Execution Environment**

The **m** adj kernel service can be called from either the process or interrupt environment.

### **Return Values**

The m adj service has no return values.

### **Related Information**

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# mbreq Structure for mbuf Kernel Services

## **Purpose**

Contains **mbuf** structure registration information for the **m reg** and **m dereg** kernel services.

## **Syntax**

```
#include <sys/mbuf.h>
struct mbreq {
                  int low mbuf;
                  int low clust;
                  int initial mbuf;
                  int initial clust;
}
```

### **Parameters**

low mbuf Specifies the **mbuf** structure low-water mark.

low clust Specifies the page-sized **mbuf** structure low-water mark.

initial mbuf Specifies the initial allocation of **mbuf** structures.

Specifies the initial allocation of page-sized mbuf structures. initial\_clust

# **Description**

The **mbreq** structure specifies the **mbuf** structure usage expectations for a user of **mbuf** kernel services.

## **Related Information**

The **m\_dereg** kernel service, **m\_reg** kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## mbstat Structure for mbuf Kernel Services

## **Purpose**

Contains mbuf usage statistics.

## **Syntax**

```
#include <sys/mbuf.h>
struct mbstat {
ulong m_mbufs;
ulong m_clusters;
ulong m spare;
ulong m clfree;
ulong m_drops;
ulong m_wait;
ulong m drain;
short m mtypes[256];
```

### **Parameters**

m_mbufs	Specifies the number of <b>mbuf</b> structures allocated.
m_clusters	Specifies the number of clusters allocated.
m_spare	Specifies the spare field.
m_clfree	Specifies the number of free clusters.
m_drops	Specifies the times failed to find space.
m_wait	Specifies the times waited for space.
m_drain	Specifies the times drained protocols for space.
m_mtypes	Specifies the type-specific <b>mbuf</b> structure allocations.

# **Description**

The mbstat structure provides usage information for the mbuf services. Statistics can be viewed through the netstat -m command.

### **Related Information**

The netstat command.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## m\_cat Kernel Service

# **Purpose**

Appends one mbuf chain to the end of another.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
void m_{cat} ( m, n)
struct mbuf *m;
struct mbuf *n;
```

## **Parameters**

Specifies the **mbuf** chain to be appended to. m

Specifies the **mbuf** chain to append. n

## **Description**

The **m** cat kernel service appends an **mbuf** chain specified by the *n* parameter to the end of **mbuf** chain specified by the *m* parameter. Where possible, compaction is performed.

#### **Execution Environment**

The **m** cat kernel service can be called from either the process or interrupt environment.

## **Return Values**

The m cat service has no return values.

#### **Related Information**

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## m\_clattach Kernel Service

## **Purpose**

Allocates an mbuf structure and attaches an external cluster.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
struct mbuf *
m_clattach( ext_buf, ext_free, ext_size, ext_arg, wait)
caddr t ext buf;
int (*ext_free)();
int ext size;
int ext arg;
int wait;
```

#### **Parameters**

ext buf Specifies the address of the external data area. Specifies the address of a function to be called when this **mbuf** structure is freed. ext\_free ext size Specifies the length of the external data area. Specifies an argument to pass to the above function. ext\_arg Specifies either the M\_WAIT or M\_DONTWAIT value. wait

# **Description**

The m\_clattach kernel service allocates an mbuf structure and attaches the cluster specified by the ext\_buf parameter. This data is owned by the caller. The m\_data field of the returned mbuf structure points to the caller's data. Interrupt handlers can call this service only with the wait parameter set to M\_DONTWAIT.

Note: The m clattach kernel service replaces the m clgetx kernel service, which is no longer supported.

The calling function is required to fill out the mbuf structure sufficiently to support normal usage. This includes support for the DMA functions during network transmission. To support DMA functions, the ext hasxm flag field needs to be set to true and the ext xmemd structure needs to be filled out. For buffers allocated from the kernel pinned heap, the ext xmemd.aspace id field should be set to XMEM\_GLOBAL.

#### **Execution Environment**

The **m** clattach kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The m\_clattach kernel service returns the address of an allocated mbuf structure. If the wait parameter is set to M\_DONTWAIT and there are no free mbuf structures, the m\_clattach service returns null.

### **Related Information**

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## m\_clget Macro for mbuf Kernel Services

## **Purpose**

Allocates a page-sized mbuf structure cluster.

# **Syntax**

```
#include <sys/mbuf.h>
int m clget ( m)
struct mbuf *m;
```

#### **Parameter**

Specifies the **mbuf** structure with which the cluster is to be associated.

# **Description**

The m clget macro allocates a page-sized mbuf cluster and attaches it to the given mbuf structure. If successful, the length of the mbuf structure is set to CLBYTES.

## **Execution Environment**

The **m** clget macro can be called from either the process or interrupt environment.

#### **Return Values**

- Indicates successful completion.
- Indicates an error.

#### **Related Information**

The m clgetm kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## m\_clgetm Kernel Service

## **Purpose**

Allocates and attaches an external buffer.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
#include <net/net_globals.h>

int
m_clgetm( m, how, size)
struct mbuf *m;
int how;
int size;
```

#### **Parameters**

m Specifies the **mbuf** structure that the cluster will be associated with.

how Specifies either the M\_DONTWAIT or M\_WAIT value.

size Specifies the size of external cluster to attach. Any value less than **MAXALLOCSAVE** is valid. For larger

values, M\_WAIT must be specified.

## **Description**

The **m\_clgetm** service allocates an **mbuf** cluster of the specified number of bytes and attaches it to the **mbuf** structure indicated by the *m* parameter. If successful, the **m\_clgetm** service sets the **M\_EXT** flag.

### **Execution Environment**

The m\_clgetm kernel service can be called from either the process or interrupt environment.

An interrupt handler can specify the *wait* parameter as **M\_DONTWAIT** only.

### **Return Values**

1 Indicates a successful operation.

If there are no free **mbuf** structures, the **m\_clgetm** kernel service returns a null value.

#### **Related Information**

The **m** free kernel service, **m** freem kernel service, **m** get kernel service.

The **m** clget macro.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# m\_collapse Kernel Service

# **Purpose**

Guarantees that an **mbuf** chain contains no more than a given number of **mbuf** structures.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
struct mbuf *m collapse ( m, size)
struct mbuf *m;
int size;
```

#### **Parameters**

Specifies the **mbuf** chain to be collapsed.

Denotes the maximum number of **mbuf** structures allowed in the chain. size

## **Description**

The m\_collapse kernel service reduces the number of mbuf structures in an mbuf chain to the number of mbuf structures specified by the size parameter. The m\_collapse service accomplishes this by copying data into page-sized mbuf structures until the chain is of the desired length. (If required, more than one page-sized **mbuf** structure is used.)

#### **Execution Environment**

The m\_collapse kernel service can be called from either the process or interrupt environment.

#### **Return Values**

If the chain cannot be collapsed into the number of **mbuf** structures specified by the *size* parameter, a value of null is returned and the original chain is deallocated. Upon successful completion, the head of the altered mbuf chain is returned.

#### **Related Information**

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# m\_copy Macro for mbuf Kernel Services

# **Purpose**

Creates a copy of all or part of a list of mbuf structures.

# **Syntax**

```
#include <sys/mbuf.h>
struct mbuf *m_copy ( m, off, len)
struct mbuf *m;
int off;
int len;
```

#### **Parameters**

m Specifies the mbuf structure, or the head of a list of mbuf structures, to be copied.

off Specifies an offset into data from which copying starts.

Denotes the total number of bytes to copy. len

## **Description**

The **m\_copy** macro makes a copy of the structure specified by the *m* parameter. The copy begins at the specified bytes (represented by the off parameter) and continues for the number of bytes specified by the len parameter. If the len parameter is set to M COPYALL, the entire mbuf chain is copied.

### **Execution Environment**

The **m\_copy** macro can be called from either the process or interrupt environment.

#### **Return Values**

Upon successful completion, the address of the copied list (the mbuf structure that heads the list) is returned. If the copy fails, a value of null is returned.

### **Related Information**

The m\_copydata kernel service, m\_copym kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## m\_copydata Kernel Service

## **Purpose**

Copies data from an **mbuf** chain to a specified buffer.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
void m_copydata (m, off, len, cp)
struct mbuf * m;
     off;
int
    len;
caddr_t cp;
```

#### **Parameters**

- Indicates the **mbuf** structure, or the head of a list of **mbuf** structures, to be copied. m
- Specifies an offset into data from which copying starts. off
- Denotes the total number of bytes to copy. len
- Points to a data buffer into which to copy the **mbuf** data.

# **Description**

The **m** copydata kernel service makes a copy of the structure specified by the *m* parameter. The copy begins at the specified bytes (represented by the off parameter) and continues for the number of bytes specified by the *len* parameter. The data is copied into the buffer specified by the *cp* parameter.

#### **Execution Environment**

The **m** copydata kernel service can be called from either the process or interrupt environment.

#### Return Values

The mcopydata service has no return values.

### **Related Information**

The **m\_copy** macro.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## m copym Kernel Service

## **Purpose**

Creates a copy of all or part of a list of **mbuf** structures.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
struct mbuf *
m_copym( m, off, len, wait)
struct mbuf m;
int off;
int len;
int wait;
```

#### **Parameters**

```
m
         Specifies the mbuf structure to be copied.
```

Specifies an offset into data from which copying will start. off

Specifies the total number of bytes to copy. len

Specifies either the M DONTWAIT or M WAIT value. wait

# **Description**

The **m\_copym** kernel service makes a copy of the **mbuf** structure specified by the *m* parameter starting at the specified offset from the beginning and continuing for the number of bytes specified by the len parameter. If the *len* parameter is set to **M COPYALL**, the entire **mbuf** chain is copied.

If the **mbuf** structure specified by the *m* parameter has an external buffer attached (that is, the **M\_EXT** flag is set), the copy is done by reference to the external cluster. In this case, the data must not be altered or both copies will be changed. Interrupt handlers can specify the wait parameter as M\_DONTWAIT only.

#### **Execution Environment**

The **m\_copym** kernel service can be called from either the process or interrupt environment.

## **Return Values**

The address of the copy is returned upon successful completion. If the copy fails, null is returned. If the wait parameter is set to M DONTWAIT and there are no free mbuf structures, the m copym kernel service returns a null value.

### **Related Information**

The m copydata kernel service.

The **m** copy macro.

## m\_dereg Kernel Service

## **Purpose**

Deregisters expected mbuf structure usage.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
void m dereg ( mbp)
struct mbreq mbp;
```

### **Parameter**

Defines the address of an **mbreq** structure that specifies expected **mbuf** usage.

## **Description**

The m\_dereg kernel service deregisters requirements previously registered with the m\_reg kernel service. The **m** dereg service is mandatory if the **m** reg service is called.

## **Execution Environment**

The **m\_dereg** kernel service can be called from the process environment only.

#### Return Values

The m\_dereg service has no return values.

#### **Related Information**

The mbreq Structure for mbuf Kernel Services.

The **m\_reg** kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# m free Kernel Service

# **Purpose**

Frees an **mbuf** structure and any associated external storage area.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
struct mbuf *m_free( m)
struct mbuf *m;
```

### **Parameter**

Specifies the **mbuf** structure to be freed. m

## **Description**

The m\_free kernel service returns an mbuf structure to the buffer pool. If the mbuf structure specified by the m parameter has an attached cluster (that is, a paged-size mbuf structure), the m free kernel service also frees the associated external storage.

#### **Execution Environment**

The **m** free kernel service can be called from either the process or interrupt environment.

#### **Return Values**

If the **mbuf** structure specified by the *m* parameter is the head of an **mbuf** chain, the **m** free service returns the next **mbuf** structure in the chain. A null value is returned if the structure specified by the m parameter is not part of an **mbuf** chain.

### **Related Information**

The m\_get kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## m freem Kernel Service

## **Purpose**

Frees an entire mbuf chain.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
void m freem ( m)
struct mbuf *m;
```

#### **Parameter**

Indicates the head of the **mbuf** chain to be freed.

# **Description**

The m\_freem kernel service starts the m\_free kernel service for each mbuf structure in the chain headed by the head specified by the *m* parameter.

#### **Execution Environment**

The **m\_freem** kernel service can be called from either the process or interrupt environment.

### **Return Values**

The **m** freem service has no return values.

## **Related Information**

The **m\_free** kernel service, **m\_get** kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## m get Kernel Service

## **Purpose**

Allocates a memory buffer (mbuf) from the **mbuf** pool.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
struct mbuf *m get ( wait, type)
int wait;
int type;
```

#### **Parameters**

wait Indicates the action to be taken if there are no free mbuf structures. Possible values are:

#### **M DONTWAIT**

Called from either an interrupt or process environment.

M WAIT

Called from a process environment.

Specifies a valid mbuf type, as listed in the /usr/include/sys/mbuf.h file. type

# **Description**

The m\_get kernel service allocates an mbuf structure of the specified type. If the buffer pool is empty and the wait parameter is set to M WAIT, the m get kernel service does not return until an mbuf structure is available.

### **Execution Environment**

The **m get** kernel service can be called from either the process or interrupt environment.

An interrupt handler can specify the *wait* parameter as **M DONTWAIT** only.

## **Return Values**

Upon successful completion, the m get service returns the address of an allocated mbuf structure. If the wait parameter is set to M DONTWAIT and there are no free mbuf structures, the m get kernel service returns a null value.

### **Related Information**

The **m\_free** kernel service, **m\_freem** kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## m\_getclr Kernel Service

## **Purpose**

Allocates and zeroes a memory buffer from the **mbuf** pool.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
struct mbuf *m getclr ( wait, type)
int wait:
int type;
```

## **Parameters**

This flag indicates the action to be taken if there are no free mbuf structures. Possible values are: wait

M DONTWAIT

Called from either an interrupt or process environment.

M WAIT

Called from a process environment only.

Specifies a valid mbuf type, as listed in the /usr/include/sys/mbuf.h file. type

## **Description**

The m\_getclr kernel service allocates an mbuf structure of the specified type. If the buffer pool is empty and the wait parameter is set to M\_WAIT value, the m\_getclr service does not return until an mbuf structure is available.

The m\_getclr kernel service differs from the m\_get kernel service in that the m\_getclr service zeroes the data portion of the allocated mbuf structure.

#### **Execution Environment**

The m getclr kernel service can be called from either the process or interrupt environment. Interrupt handlers can call the m\_getclr service only with the wait parameter set to the M\_DONTWAIT value.

#### **Return Values**

The m\_getclr kernel service returns the address of an allocated mbuf structure. If the wait parameter is set to the M DONTWAIT value and there are no free mbuf structures, the m getclr kernel service returns a null value.

#### **Related Information**

The **m** free kernel service, **m** freem kernel service, **m** get kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# m\_getclust Macro for mbuf Kernel Services

# **Purpose**

Allocates an **mbuf** structure from the **mbuf** buffer pool and attaches a page-sized cluster.

## **Syntax**

```
#include <sys/mbuf.h>
struct mbuf *m getclust ( wait, type)
int wait;
int type;
```

### **Parameters**

Indicates the action to be taken if there are no available **mbuf** structures. Possible values are: wait

M DONTWAIT

Called from either an interrupt or process environment.

M WAIT

Called from a process environment only.

Specifies a valid mbuf type from the /usr/include/sys/mbuf.h file. type

## **Description**

The **m getclust** macro allocates an **mbuf** structure of the specified type. If the allocation succeeds, the m\_getclust macro then attempts to attach a page-sized cluster to the structure.

If the buffer pool is empty and the wait parameter is set to M\_WAIT, the m\_getclust macro does not return until an mbuf structure is available.

#### **Execution Environment**

The **m getclust** macro can be called from either the process or interrupt environment.

#### **Return Values**

The address of an allocated mbuf structure is returned on success. If the wait parameter is set to M DONTWAIT and there are no free mbuf structures, the m getclust macro returns a null value.

### **Related Information**

The m\_getclustm kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# m\_getclustm Kernel Service

# **Purpose**

Allocates an **mbuf** structure and attaches a cluster of the specified size, both from the **mbuf** buffer pool.

# **Syntax**

```
#include <sys/mbuf.h>
#include <net/net_globals.h>
struct mbuf *
m getclustm( wait, type, size)
int wait;
int type;
int size;
```

### **Parameters**

wait Specifies either the M DONTWAIT or M WAIT	Γvalue.
--	---------

type Specifies a valid **mbuf** type from the /usr/include/sys/mbuf.h file.

size Specifies the size of the external cluster to attach. Any value less than **MAXALLOCSAVE** is valid. For larger values, **M\_WAIT** must be specified.

## **Description**

The m\_getclustm service allocates an mbuf structure of the specified type. If successful, the m\_getclustm service then attempts to attach a cluster of the indicated size (specified by the *size* parameter) to the mbuf structure. If the buffer pool is empty and the *wait* parameter is set to M\_WAIT, the m\_get service does not return until an mbuf structure is available. Interrupt handlers should call this service only with the *wait* parameter set to M\_DONTWAIT.

### **Execution Environment**

The **m\_getclustm** kernel service can be called from either the process or interrupt environment.

An interrupt handler can specify the wait parameter as M\_DONTWAIT only.

#### **Return Values**

The **m\_getclustm** kernel service returns the address of an allocated **mbuf** structure on success. If the *wait* parameter is set to **M\_DONTWAIT** and there are no free **mbuf** structures, the **m\_getclustm** kernel service returns null.

### **Related Information**

The m clget kernel service, m free kernel service, m freem kernel service, m get kernel service.

The **m\_getclust** macro.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# m\_gethdr Kernel Service

# **Purpose**

Allocates a header memory buffer from the **mbuf** pool.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>

struct mbuf *
m_gethdr ( wait, type)
int wait;
int type;
```

#### **Parameters**

```
wait Specifies either the M_DONTWAIT or M_WAIT value.
```

type Specifies the valid **mbuf** type from the /usr/include/sys/mbuf.h file.

## **Description**

The **m gethdr** kernel service allocates an **mbuf** structure of the specified type. If the buffer pool is empty and the wait parameter is set to M\_WAIT, the m\_gethdr kernel service will not return until an mbuf structure is available. Interrupt handlers should call this kernel service only with the wait parameter set to M DONTWAIT. The M PKTHDR flag is set for the returned mbuf structure.

### **Execution Environment**

The m\_gethdr kernel service can be called from either the process or interrupt environment.

An interrupt handler can specify the *wait* parameter as **M\_DONTWAIT** only.

### **Return Values**

The address of an allocated mbuf structure is returned on success. If the wait parameter is set to M DONTWAIT and there are no free mbuf structure, the m gethdr kernel service returns null.

## **Related Information**

The m free kernel service, m freem kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## M HASCL Macro for mbuf Kernel Services

## **Purpose**

Determines if an **mbuf** structure has an attached cluster.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
struct mbuf * m;
M HASCL (m);
```

#### **Parameter**

Indicates the address of the **mbuf** structure in question.

# **Description**

The M HASCL macro determines if an mbuf structure has an attached cluster.

### **Execution Environment**

The M\_HASCL macro can be called from either the process or interrupt environment.

# Example

The **M\_HASCL** macro can be used as in the following example:

```
struct mbuf *m;
if (M HASCL(m))
  printf("mbuf has attached cluster");
```

## **Related Information**

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# m\_pullup Kernel Service

## **Purpose**

Adjusts an **mbuf** chain so that a given number of bytes is in contiguous memory in the data area of the head **mbuf** structure.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>

struct mbuf *m_pullup ( m, size)
struct mbuf *m;
int size:
```

## **Parameters**

m Specifies the **mbuf** chain to be adjusted.size Specifies the number of bytes to be contiguous.

# **Description**

The **m\_pullup** kernel service guarantees that the **mbuf** structure at the head of a chain has in contiguous memory within its data area at least the number of data bytes specified by the *size* parameter.

## **Execution Environment**

The **m\_pullup** kernel service can be called from either the process or interrupt environment.

#### **Return Values**

Upon successful completion, the head structure in the altered **mbuf** chain is returned.

A value of null is returned and the original chain is deallocated under the following circumstances:

- The size of the chain is less than indicated by the *size* parameter.
- The number indicated by the size parameter is greater than the data portion of the head-size mbuf structure.

#### **Related Information**

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# m\_reg Kernel Service

# **Purpose**

Registers expected **mbuf** usage.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
void m reg ( mbp)
struct mbreq mbp;
```

#### **Parameter**

Defines the address of an **mbreq** structure that specifies expected **mbuf** usage.

## **Description**

The m\_reg kernel service lets users of mbuf services specify initial requirements. The m\_reg kernel service also allows the buffer pool low-water and deallocation marks to be adjusted based on expected usage. Its use is recommended for better control of the buffer pool.

When the number of free **mbuf** structures falls below the low-water mark, the total **mbuf** pool is expanded. When the number of free **mbuf** structures rises above the deallocation mark, the total **mbuf** pool is contracted and resources are returned to the system.

### **Execution Environment**

The m\_reg kernel service can be called from the process environment only.

#### **Return Values**

The **m** reg service has no return values.

#### **Related Information**

The **mbreq** structure for **mbuf** kernel services, the **m dereg** kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## md\_restart\_block\_read Kernel Service

# **Purpose**

A copy of the RESTART\_BLOCK structure in the NVRAM header will be placed in the caller's buffer.

# **Syntax**

```
#include <sys/mdio.h>
int md restart block read (md)
                struct mdio *md;
```

### **Parameters**

md Specifies the address of the mdio structure. The mdio structure contains the following fields:

md\_data

Pointer to the data buffer.

md\_size

Number of bytes in the data buffer.

md\_addr

Contains the value PMMode on return in the least significant byte.

## **Description**

The RestartBlock which is in the **NVRAM** header will be copied to the user supplied buffer. This block is a communication vehicle for the software and the firmware.

### **Return Values**

Returns 0 for successful completion.

**ENOMEM** Indicates that there was not enough room in the user supplied buffer to contain the RestartBlock.

**EINVAL** Indicates this is not a PowerPC<sup>®</sup> reference platform.

## **Prerequisite Information**

Kernel Extensions and Device Driver Management Kernel Services in Kernel Extensions and Device Support Programming Concepts.

#### **Related Information**

Machine Device Driver in AIX Version 7.1 Technical Reference: Kernel and Subsystems, Volume 2.

# md\_restart\_block\_upd Kernel Service

# **Purpose**

The caller supplied RestartBlock will be copied to the NVRAM header.

# **Syntax**

# **Description**

The 8-bit value in *pmmode* will be stored into the **NVRAM** header at the PMMode offset. The Restart Block which is in the caller's buffer will be copied to the **NVRAM** after the Restart Block checksum is calculated and a new Crc1 value is computed.

#### **Parameters**

md Specifies the address of the mdio structure. The mdio structure contains the following fields:

md data

Pointer to the RestartBlock structure..

pmmode Value to be stored into PMMode in the NVRAM header.

## **Return Values**

Returns 0 for successful completion.

**EINVAL** 

Indicates this is not a PowerPC® reference platform.

## **Prerequisite Information**

Kernel Extensions and Device Driver Management Kernel Services in Kernel Extensions and Device Support Programming Concepts.

### **Related Information**

Machine Device Driver in AIX Version 7.1 Technical Reference: Kernel and Subsystems, Volume 2.

## MTOCL Macro for mbuf Kernel Services

## **Purpose**

Converts a pointer to an **mbuf** structure to a pointer to the head of an attached cluster.

## **Syntax**

```
#include <sys/mbuf.h>
struct mbuf * m;
MTOCL (m);
```

#### **Parameter**

m Indicates the address of the mbuf structure in question.

# **Description**

The MTOCL macro converts a pointer to an mbuf structure to a pointer to the head of an attached cluster.

The MTOCL macro can be used as in the following example:

```
caddr t attcls;
struct mbuf
attcls = (caddr t) MTOCL(m);
```

#### **Execution Environment**

The MTOCL macro can be called from either the process or interrupt environment.

## **Related Information**

The M HASCL macro for mbuf kernel services.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## **MTOD Macro for mbuf Kernel Services**

## **Purpose**

Converts a pointer to an **mbuf** structure to a pointer to the data stored in that **mbuf** structure.

## **Syntax**

```
#include <sys/mbuf.h>
MTOD ( m, type);
```

### **Parameters**

```
m Identifies the address of an mbuf structure.type Indicates the type to which the resulting pointer should be cast.
```

## **Description**

The **MTOD** macro converts a pointer to an **mbuf** structure into a pointer to the data stored in the **mbuf** structure. This macro can be used as in the following example:

```
char *bufp;
bufp = MTOD(m, char *);
```

## **Execution Environment**

The MTOD macro can be called from either the process or interrupt environment.

## **Related Information**

The DTOM macro for mbuf Kernel Services.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# **M\_XMEMD Macro for mbuf Kernel Services**

# **Purpose**

Returns the address of an **mbuf** cross-memory descriptor.

# **Syntax**

#### **Parameter**

M Specifies the address of the **mbuf** structure in question.

# **Description**

The **M\_XMEMD** macro returns the address of an **mbuf** cross-memory descriptor.

## **Execution Environment**

The **M\_XMEMD** macro can be called from either the process or interrupt environment.

## **Example**

The **M\_XMEMD** macro can be used as in the following example:

```
struct mbuf
struct xmem *xmemd;
xmemd = M XMEMD(m);
```

### **Related Information**

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# mycpu Kernel Service

## **Purpose**

Gets the bind ID of the processor we are running on.

## **Syntax**

```
#include <sys/processor.h>
cpu_t myc ()
```

## **Description**

The **mycpu** kernel service returns the bind ID of the processor we are currently running on.

### **Execution Environment**

The **mycpu** kernel services can be called from either the process or interrupt environment. This routine must be called disabled. Otherwise, the calling thread might be preempted and resume execution on a different processor resulting in a stale value being returned.

### **Return Values**

The **mycpu** kernel service returns the bind ID of the current processor.

#### **Related Information**

The bindprocessor kernel service.

## net attach Kernel Service

# **Purpose**

Opens a communications I/O device handler.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <aixif/net if.h>
#include <sys/comio.h>
int net_attach (kopen ext, device req, netid, netfpp)
struct kopen_ext * kopen_ext;
```

```
struct device_req * device_req;
struct netid_list * netid;
struct file ** netfpp;
```

#### **Parameters**

kopen\_extSpecifies the device handler kernel open extension.device\_reqIndicates the address of the device description structure.

netid Indicates the address of the network ID list.

netfpp Specifies the address of the variable that will hold the returned file pointer.

## **Description**

The **net\_attach** kernel service opens the device handler specified by the *device\_req* parameter and then starts all the network IDs listed in the address specified by the *netid* parameter. The **net\_attach** service then sleeps and waits for the asynchronous start completion notifications from the **net\_start\_done** kernel service.

## **Execution Environment**

The **net\_attach** kernel service can be called from the process environment only.

#### **Return Values**

Upon success, a value of 0 is returned and a file pointer is stored in the address specified by the *netfpp* parameter. Upon failure, the **net\_attach** service returns either the error codes received from the **fp\_opendev** or **fp\_ioctl** kernel service, or the value **ETIMEDOUT**. The latter value is returned when an open operation times out.

### **Related Information**

The net\_detach kernel service, net\_start kernel service, net\_start\_done kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## net\_detach Kernel Service

# **Purpose**

Closes a communications I/O device handler.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <aixif/net_if.h>

int net_detach ( netfp)
struct file *netfp;
```

### **Parameter**

netfp Points to an open file structure obtained from the **net\_attach** kernel service.

## **Description**

The net\_detach kernel service closes the device handler associated with the file pointer specified by the netfp parameter.

### **Execution Environment**

The **net\_detach** kernel service can be called from the process environment only.

### **Return Values**

The **net detach** service returns the value it obtains from the **fp close** service.

#### Related Information

The fp\_close kernel service, net\_attach kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## net error Kernel Service

## **Purpose**

Handles errors for communication network interface drivers.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>
#include <sys/comio.h>
net_error ( ifp, error_code, netfp)
struct ifnet *ifp;
int error code;
struct file *netfp;
```

## **Parameters**

Specifies the error code listed in the /usr/include/sys/comio.h file. error code Specifies the address of the ifnet structure for the device with an error. ifp

Specifies the file pointer for the device with an error. netfp

# **Description**

The **net error** kernel service provides generic error handling for communications network interface (if) drivers. Network interface (if) kernel extensions call this service to trace errors and, in some instances, perform error recovery.

Errors traced include those:

- · Received from the communications adapter drivers.
- · Occurring during input and output packet processing.

#### **Execution Environment**

The **net error** kernel service can be called from either the process or interrupt environment.

## **Return Values**

The **net error** service has no return values.

#### **Related Information**

The net\_attach kernel service, net\_detach kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## net sleep Kernel Service

## **Purpose**

Sleeps on the specified wait channel.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pri.h>
net_sleep ( chan, flags)
int chan;
int flags;
```

### **Parameters**

chan Specifies the wait channel to sleep upon.

flags Sleep flags described in the **sleep** kernel service.

# **Description**

The net\_sleep kernel service puts the caller to sleep waiting on the specified wait channel. If the caller holds the network lock, the net\_sleep kernel service releases the lock before sleeping and reacquires the lock when the caller is awakened.

#### **Execution Environment**

The **net\_sleep** kernel service can be called from the process environment only.

### **Return Values**

- Indicates that the sleeping process was not awakened by a signal.
- Indicates that the sleeper was awakened by a signal.

### **Related Information**

The **net wakeup** kernel service, **sleep** kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## net\_start Kernel Service

## **Purpose**

Starts network IDs on a communications I/O device handler.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <aixif/net_if.h>
#include <sys/comio.h>
struct file *net_start ( netfp, netid)
struct file *netfp;
struct netid list *netid;
```

### **Parameters**

Specifies the file pointer of the device handler. netfp Specifies the address of the network ID list. netid

## **Description**

The **net\_start** kernel service starts all the network IDs listed in the list specified by the *netid* parameter. This service then waits for the asynchronous notification of completion of starts.

## **Execution Environment**

The net\_start kernel service can be called from the process environment only.

#### **Return Values**

The net start service uses the return value returned from a call to the fp ioctl service requesting the **CIO START** operation.

**ETIMEDOUT** 

Indicates that the start for at least one network ID timed out waiting for start-done notifications from the device handler.

#### **Related Information**

The fp\_ioctl kernel service, net\_attach kernel service, net\_start\_done kernel service,.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## net\_start\_done Kernel Service

# **Purpose**

Starts the done notification handler for communications I/O device handlers.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <aixif/net_if.h>
#include <sys/comio.h>
void net_start_done ( netid, sbp)
struct netid_list *netid;
struct status_block *sbp;
```

#### **Parameters**

netid Specifies the address of the network ID list for the device being started. Specifies the status block pointer returned from the device handler. sbp

## **Description**

The net\_start\_done kernel service is used to mark the completion of a network ID start operation. When all the network IDs listed in the *netid* parameter have been started, the **net attach** kernel service returns to the caller. The net\_start\_done service should be called when a CIO\_START\_DONE status block is received from the device handler. If the status block indicates an error, the start process is immediately aborted.

### **Execution Environment**

The **net\_start\_done** kernel service can be called from either the process or interrupt environment.

## **Return Values**

The **net start done** service has no return values.

### **Related Information**

The **net\_attach** kernel service, **net\_start** kernel service.

The CIO START DONE status block.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# net\_wakeup Kernel Service

# **Purpose**

Wakes up all sleepers waiting on the specified wait channel.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
net wakeup ( chan)
int chan;
```

### **Parameter**

chan Specifies the wait channel.

## **Description**

The net\_wakeup service wakes up all network processes sleeping on the specified wait channel.

### **Execution Environment**

The **net wakeup** kernel service can be called from either the process or interrupt environment.

### **Return Values**

The net\_wakeup service has no return values.

#### Related Information

The **net\_sleep** kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## net xmit Kernel Service

## **Purpose**

Transmits data using a communications device handler.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <aixif/net_if.h>
int net xmit (ifp, m, netfp, lngth, m ext)
struct ifnet * ifp;
struct mbuf * m;
struct file * netfp;
     lngth;
struct mbuf * m ext;
```

### **Parameters**

ifp Indicates an address of the ifnet structure for this interface.

Specifies the address of an **mbuf** structure containing the data to transmit. m netfp Indicates the open file pointer obtained from the **net\_attach** kernel service.

Indicates the total length of the buffer being transmitted. Ingth

Indicates the address of an mbuf structure containing a write extension. m\_ext

# **Description**

The net\_xmit kernel service builds a uio structure and then invokes the fp\_rwuio service to transmit a packet. The net\_xmit\_trace kernel service is an alternative for network interfaces that choose not to use the net xmit kernel service.

### **Execution Environment**

The net\_xmit kernel service can be called from either the process or interrupt environment.

## **Return Values**

Indicates that the packet was transmitted successfully. **ENOBUFS** Indicates that buffer resources were not available.

The **net xmit** kernel service returns a value from the **fp rwuio** service when an error occurs during a call to that service.

#### **Related Information**

The fp rwuio kernel service, net xmit trace kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## net xmit trace Kernel Service

## **Purpose**

Traces transmit packets.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int net_xmit_trace ( ifp, mbuf )
struct ifnet *ifp;
struct mbuf *mbuf;
```

#### **Parameters**

Designates the address of the ifnet structure for this interface. ifp mbuf Designates the address of the **mbuf** structure to be traced.

# **Description**

The net\_xmit\_trace kernel service traces the data pointed to by the mbuf parameter. This kernel service was added for those network interfaces that choose not to use the net xmit kernel service to transmit packets. An application program (the iptrace command) reads the trace data and writes it to a file for the **ipreport** command to interpret.

### **Execution Environment**

The net\_xmit\_trace kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The **net xmit trace** kernel service has no return values.

#### **Related Information**

The net xmit kernel service.

The **ipreport** command.

The iptrace daemon.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# **NLuprintf Kernel Service**

## **Purpose**

Submits a request to print an internationalized message to a process' controlling terminal.

## **Syntax**

#include <sys/uprintf.h> int NLuprintf (Uprintf) struct uprintf \*Uprintf;

### **Parameters**

Uprintf

Points to a uprintf request structure.

## **Description**

The NLuprintf kernel service submits a internationalized kernel message request with the uprintf request structure specified by the *Uprintf* parameter as input. Once the request has been successfully submitted, the uprintfd daemon retrieves, converts, formats, and writes the message described by the uprintf request structure to a process' controlling terminal.

The caller must initialize the uprintf request structure before calling the NLuprintf kernel service. Fields in the uprintf request structure use several constants. The following constants are defined in the /usr/include/sys/uprintf.h file:

- UP MAXSTR
- UP MAXARGS
- UP MAXCAT
- UP MAXMSG

The **uprintf** request structure consists of the following fields:

#### Field

Uprintf->upf defmsg

Uprintf->upf arg[UP MAXARGS]

#### Description

Points to a default message format. The default message format is a character string that contains either or both of two types of objects:

- · Plain characters, which are copied to the message output stream
- Conversion specifications, each of which causes zero or more items to be fetched from the *Uprintf->arg* value parameter array

Each conversion specification consists of a % (percent sign) followed by a character that indicates the type of conversion to be applied:

- % Performs no conversion. Prints a % character.
- d, i Accepts an integer value and converts it to signed decimal notation.
- Accepts an integer value and converts it to unsigned u decimal notation.
- Accepts an integer value and converts it to unsigned 0 octal notation.
- Accepts an integer value and converts it to unsigned X hexadecimal notation.
- Accepts and prints a char value. C
- Accepts a value as a string (character pointer). S Characters from the string are printed until a \0 (null character) is encountered.

Field-width or precision conversion specifications are not supported.

The maximum length of the default message-format string pointed to by the Uprintf->upf\_defmsg field is the number of characters specified by the UP\_MAXSTR constant. The Uprintf->upf defmsg field must be a nonnull character.

The default message format is used in constructing the kernel message if the message format described by the Uprintf->upf NLsetno and Uprint->upf NLmsgno fields cannot be retrieved from the message catalog specified by Uprintf->upf NLcatname. The conversion specifications contained within the default message format should match those contained in the message format specified by the upf NLsetno and upf NLmsgno fields.

Specifies from zero to the number of value parameters specified by the **UP MAXARGS** constant. A *Value* parameter may be a integer value, a character value, or a string value (character pointer). Strings are limited in length to the number of characters specified by the UP\_MAXSTR constant. String value parameters must be nonnull characters. The number, type, and order of items in the Value parameter array should match the conversion specifications within the message format string.

Field Description

Points to the message catalog file name. If the catalog file Uprintf->upf NLcatname name referred to by the Uprintf->upf NLcatname field begins

> with a / (slash), it is assumed to be an absolute path name. If the catalog file name is not an absolute path name, the process environment determines the directory paths to search. The maximum length of the catalog file name is limited to the number of characters specified by the **UP\_MAXCAT** constant.

The value of the Uprintf->upf NLcatname field must be a nonnull character.

Specifies the set ID. Uprintf->upf NLsetno

Specifies the message ID. The Uprintf->upf NLsetno and Uprintf->upf NLmsqno Uprintf->upf NLmsqno fields specify a particular message format string to be retrieved from the message catalog

specified by the Uprintf->upf NLcatname field.

The maximum length of the constructed kernel message is limited to the number of characters specified by the UP\_MAXMSG constant. Messages larger then the number of characters specified by the UP\_MAXMSG constant are

discarded.

### **Execution Environment**

The NLuprintf kernel service can be called from the process environment only.

## **Return Values**

Indicates a successful operation.

ENOMEM Indicates that memory is not available to buffer the request.

**ENODEV** Indicates that a controlling terminal does not exist for the process.

**ESRCH** Indicates the uprintfd daemon is not active. No requests may be submitted.

**EINVAL** Indicates that the message catalog file-name pointer is null or the catalog file name is greater than the

number of characters specified by the UP\_MAXCAT constant.

**EINVAL** Indicates that a string-value parameter pointer is null or the string-value parameter is greater than the

number of characters specified by the UP\_MAXCAT constant.

**EINVAL** Indicates one of the following:

· Default message format pointer is null.

- Number of characters in the default message format is greater than the number specified by the **UP MAXSTR** constant.
- · Number of conversion specifications contained within the default message format is greater than the number specified by the UP\_MAXARGS constant.

#### **Related Information**

The uprintf kernel service.

The **uprintfd** daemon.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## ns\_add\_demux Network Kernel Service

## **Purpose**

Adds a demuxer for the specified type of network interface.

## **Syntax**

```
#include <sys/ndd.h>
#include <sys/cdli.h>
int ns add demux (ndd type, demux)
       u long ndd type;
       struct ns demuxer * demux;
```

#### **Parameters**

ndd\_type Specifies the interface type of the demuxer to be added.

demux Specifies the pointer to an **ns\_demux** structure that defines the demuxer.

# **Description**

The ns\_add\_demux network service adds the specified demuxer to the list of available network demuxers. Only one demuxer per network interface type can exist. An interface type describes a certain class of network devices that have the same characteristics (such as ethernet or token ring). The values of the ndd\_type parameter listed in the /usr/include/sys/ndd.h file are the numbers defined by Simple Network Management Protocol (SNMP). If the desired type is not in the **ndd.h** file, the SNMP value should be used if it is defined. Otherwise, any undefined type above NDD\_MAX\_TYPE may be used.

Note: The ns\_demuxer structure must be allocated and pinned by the network demuxer.

# **Examples**

The following example illustrates the **ns\_add\_demux** network service:

```
struct ns demuxer demuxer;
bzero (&demuxer, sizeof (demuxer));
demuxer.nd_add_filter = eth_add_filter;
demuxer.nd_del_filter = eth_del_filter;
demuxer.nd_add_status = eth_add_status;
demuxer.nd del status = eth del status;
demuxer.nd receive = eth receive;
demuxer.nd_status = eth status;
demuxer.nd response = eth response;
demuxer.nd use nsdnx = 1;
ns_add_demux(NDD_IS088023, &demuxer);
```

### **Return Values**

Indicates the operation was successful.

**EEXIST** Indicates a demuxer already exists for the given type.

### **Related Information**

The **ns** del demux network service.

## ns\_add\_filter Network Service

## **Purpose**

Registers a receive filter to enable the reception of packets.

## **Syntax**

#### **Parameters**

nddp Specifies the **ndd** structure to which this add request applies.

filter Specifies the pointer to the receive filter.

*len* Specifies the length in bytes of the receive filter to which the *filter* parameter points.

ns\_user Specifies the pointer to a ns\_user structure that defines the user.

## **Description**

The ns\_add\_filter network service registers a receive filter for the reception of packets and enables a network demuxer to route packets to the appropriate users. The add request is passed on to the nd\_add\_filter function of the demuxer for the specified NDD. The caller of the ns\_add\_filter network service is responsible for relinquishing filters before calling the ns\_free network service.

# **Examples**

The following example illustrates the **ns\_add\_filter** network service:

```
struct ns_8022 dl;
struct ns_user ns_user;

dl.filtertype = NS_LLC_DSAP_SNAP;
dl.dsap = 0xaa;
dl.orgcode[0] = 0x0;
dl.orgcode[1] = 0x0;
dl.orgcode[2] = 0x0;
dl.ethertype = 0x0800;

ns_user.isr = NULL;
ns_user.isr_data = NULL;
ns_user.protoq = &ipintrq;
ns_user.netisr = NETISR_IP;
ns_user.ifp = ifp;
ns_user.pkt_format = NS_PROTO_SNAP;
ns add filter(nddp, &dl, sizeof(dl), &ns_user);
```

There are two ways a user (that is, the entity that is interested in receiving incoming packets) can be invoked when a packet arrives. In the first method, a protocol queue can be defined in which incoming packets are queued upon receipt, and the specified *netisr* is scheduled to let the user know that there are new packets in the queue. For example, the preceding code assumes a network interrupt service request (netisr) with the name **NETISR\_IP** has been defined. When a packet arrives for the specified user, the

packet is queued on the specified protocol queue (in this case, **ipintrq**) and the **NETISR\_IP** request is scheduled to be executed. Because of its complexity, this mode is not currently being used by any network user.

The preferred way of receiving incoming packets is by registering an interrupt service request (isr) function that handles incoming packets; **ns\_user.isr** points to the function that will get invoked whenever a packet that matches the specified filter arrives. This function should expect the following four arguments:

```
void isr (ndd t *nddp, mbuf *m, caddr t macp, caddr t extp)
```

#### where

nddp Pointer to the **ndd** structure representing the adapter where the packet was received.

m Pointer to the **mbuf** structure representing the packet that was received.

macp Pointer to the start of the MAC header of the packet that was received.

extp Pointer to the (optional) structure specified in ns\_user.isr\_data, or NULL if none was specified.

In the following code, the function **bpf\_cdli\_tap** will be called when a new packet arrives; a pointer to the **bp** structure will be passed as the fourth parameter when **bpf\_cdli\_tap** is called.

```
dl.filtertype = NS_TAP;

ns_user.isr = bpf_cdli_tap;
ns_user.isr_data = (caddr_t) bp;
ns_user.protoq = (struct ifqueue *) NULL;
ns_user.netisr = 0;
ns_user.ifp = (struct ifnet *) NULL;
ns user.pkt format = NS INCLUDE MAC;
```

**Note:** Both modes of receiving packets are mutually exclusive. In other words, if the **ns\_user.protoq** member is non-null, the protocol queue method is used; otherwise, the direct isr function method is used, and the **ns user.isr** function pointer must be a valid function pointer.

In both cases, **ns\_user.ifp** can optionally point to the **ifnet** structure of the interface where the packets will be received. If it is non-null, the state of the interface will be verified when a packet is received. If the interface is not up, the packet will be dropped and it will not be delivered to the user. If the interface is up, the statistics for the number of received packets will be incremented, and the ifp will be saved in the packet's **mbuf** structure's **m\_pkthdr.rcvif** field.

The **ns\_user.pkt\_format** member determines how much of the MAC header the user is interested in receiving. Its possible values are:

NS\_PROTO Do not include the LLC header (but include the SNAP header, if there is one).

NS\_PROTO\_SNAP
Do not include the LLC SNAP header (that is, remove the entire MAC header)

and deliver only the data).

NS\_INCLUDE\_LLC Include the LLC header.

NS\_INCLUDE\_MAC Include the entire MAC header.

#### **NS\_HANDLE\_HEADERS**

Instead of passing the specified ns\_user.isr\_data structure by itself, build an isr\_data\_ext structure containing header information, as well as a pointer to the specified ns\_user.isr\_data. These are the fields that will be set in the isr\_data\_ext structure:

#### isr\_data\_ext.isr\_data

Pointer to the structure passed as ns\_user.isr\_data.

#### isr\_data\_ext.dstp

Pointer to the destination MAC address.

#### isr data ext.dstlen

Length of the destination MAC address.

#### isr\_data\_ext.srcp

Pointer to the source MAC address.

#### isr\_data\_ext.seclen

Length of the source MAC address.

#### isr data ext.seqp

Pointer to the routing segment.

#### isr data ext.seglen

Length of the routing segment.

#### isr\_data\_ext.llcp

Pointer to the LLC.

#### isr\_data\_ext.llclen

Length of the LLC.

It is possible to combine NS\_HANDLE\_HEADERS with one of the other flags by means of a logical OR operator (for example, ns user.pkt format = NS INCLUDE MAC | NS HANDLE HEADERS). The other flags, however, are mutually exclusive.

### **Return Values**

0 Indicates the operation was successful.

The network demuxer may supply other return values.

#### **Related Information**

The **ns\_del\_filter** network service.

# ns\_add\_status Network Service

# **Purpose**

Adds a status filter for the routing of asynchronous status.

# **Syntax**

```
#include <sys/cdli.h>
#include <sys/ndd.h>
int ns_add_status (nddp, statfilter, len, ns_statuser)
       struct ndd * nddp;
```

```
caddr_t statfilter;
int len;
struct ns_statuser * ns_statuser;
```

### **Parameters**

nddp Specifies a pointer to the **ndd** structure to which this add request applies.

statfilter Specifies a pointer to the status filter.

len Specifies the length, in bytes, of the value of the statfilter parameter.ns\_statuser Specifies a pointer to an ns\_statuser structure that defines this user.

## **Description**

The **ns\_add\_status** network service registers a status filter. The add request is passed on to the **nd\_add\_status** function of the demuxer for the specified network device driver (NDD). This network service enables the user to receive asynchronous status information from the specified device.

**Note:** The user's status processing function is specified by the isr field of the **ns\_statuser** structure. The network demuxer calls the user's status processing function directly when asynchronous status information becomes available. Consequently; the status processing function cannot be a scheduled routine. The caller of the **ns\_add\_status** network service is responsible for relinquishing status filters before calling the **ns\_free** network service.

# **Examples**

The following example illustrates the **ns\_add\_status** network service:

```
struct ns_statuser user;
struct ns_com_status filter;

filter.filtertype = NS_STATUS_MASK;
filter.mask = NDD_HARD_FAIL;
filter.sid = 0;
user.isr = status_fn;
user.isr_data = whatever_makes_sense;
error = ns_add_status(nddp, &filter, sizeof(filter), &user);
```

### **Return Values**

Indicates the operation was successful.

The network demuxer may supply other return values.

#### **Related Information**

The ns\_del\_status network service.

### ns\_alloc Network Service

# **Purpose**

Allocates use of a network device driver (NDD).

# **Syntax**

#include <sys/ndd.h>

```
int ns_alloc (nddname, nddpp)
       char * nddname;
       struct ndd ** nddpp;
```

### **Parameters**

nddname Specifies the device name to be allocated.

nddpp Indicates the address of the pointer to a **ndd** structure.

## **Description**

The ns alloc network service searches the Network Service (NS) device chain to find the device driver with the specified *nddname* parameter. If the service finds a match, it increments the reference count for the specified device driver. If the reference count is incremented to 1, the ndd open subroutine specified in the **ndd** structure is called to open the device driver.

## **Examples**

The following example illustrates the **ns\_alloc** network service:

```
struct ndd
           *nddp;
error = ns alloc("en0", &nddp);
```

### **Return Values**

If a match is found and the **ndd\_open** subroutine to the device is successful, a pointer to the **ndd** structure for the specified device is stored in the nddpp parameter. If no match is found or the open of the device is unsuccessful, a non-zero value is returned.

Indicates the operation was successful. **ENODEV** Indicates an invalid network device.

**ENOENT** Indicates no network demuxer is available for this device.

The **ndd\_open** routine may specify other return values.

#### **Related Information**

The ns free network service.

# ns attach Network Service

# **Purpose**

Attaches a network device to the network subsystem.

# **Syntax**

```
#include <sys/ndd.h>
int ns_attach (nddp)
       struct ndd * nddp;
```

### **Parameters**

nddp Specifies a pointer to an **ndd** structure describing the device to be attached.

## **Description**

The **ns\_attach** network service places the device into the available network service (NS) device chain. The network device driver (NDD) should be prepared to be opened after the **ns\_attach** network service is called.

Note: The ndd structure is allocated and initialized by the device. It should be pinned.

## **Examples**

The following example illustrates the **ns\_attach** network service:

### **Return Values**

Indicates the operation was successful.

**EEXIST** Indicates the device is already in the available NS device chain.

#### **Related Information**

The ns\_detach network service.

## ns\_del\_demux Network Service

# **Purpose**

Deletes a demuxer for the specified type of network interface.

# **Syntax**

### **Parameters**

ndd\_type Specifies the network interface type of the demuxer that is to be deleted.

## **Description**

If the demuxer is not currently in use, the **ns\_del\_demux** network service deletes the specified demuxer from the list of available network demuxers. A demuxer is in use if a network device driver (NDD) is open for the demuxer.

## **Examples**

The following example illustrates the **ns\_del\_demux** network service:

```
ns del demux(NDD IS088023);
```

### **Return Values**

Indicates the operation was successful.

**ENOENT** Indicates the demuxer of the specified type does not exist.

### **Related Information**

The ns\_add\_demux network service.

### ns\_del\_filter Network Service

## **Purpose**

Deletes a receive filter.

# **Syntax**

### **Parameters**

nddp Specifies the **ndd** structure that this delete request is for.

filter Specifies the pointer to the receive filter.

len Specifies the length in bytes of the receive filter.

# Description

The **ns\_del\_filter** network service deletes the receive filter from the corresponding network demuxer. This disables packet reception for packets that match the filter. The delete request is passed on to the **nd del filter** function of the demuxer for the specified network device driver (NDD).

# **Examples**

The following example illustrates the **ns del filter** network service:

```
struct ns_8022 dl;
dl.filtertype = NS_LLC_DSAP_SNAP;
dl.dsap = 0xaa;
dl.orgcode[0] = 0x0;
```

```
dl.orgcode[1] = 0x0;
dl.orgcode[2] = 0x0;
dl.ethertype = 0x0800;
ns_del_filter(nddp, &dl, sizeof(dl));
```

### **Return Values**

0 Indicates the operation was successful.

The network demuxer may supply other return values.

### **Related Information**

The ns\_add\_filter network service, ns\_alloc network service.

### ns\_del\_status Network Service

## **Purpose**

Deletes a previously added status filter.

# **Syntax**

#### **Parameters**

nddp Specifies the pointer to the **ndd** structure to which this delete request applies.

statfilter Specifies the pointer to the status filter.

len Specifies the length, in bytes, of the value of the statfilter parameter.

# **Description**

The **ns\_del\_status** network service deletes a previously added status filter from the corresponding network demuxer. The delete request is passed on to the **nd\_del\_status** function of the demuxer for the specified network device driver (NDD). This network service disables asynchronous status notification from the specified device.

# **Examples**

The following example illustrates the **ns\_del\_status** network service:

```
error = ns_add_status(nddp, &filter,
sizeof(filter));
```

### **Return Values**

0 Indicates the operation was successful.

The network demuxer may supply other return values.

### **Related Information**

The ns\_add\_status network service.

## ns\_detach Network Service

## **Purpose**

Removes a network device from the network subsystem.

## **Syntax**

```
#include <sys/ndd.h>
int ns detach (nddp)
       struct ndd * nddp;
```

### **Parameters**

nddp Specifies a pointer to an **ndd** structure describing the device to be detached.

# **Description**

The ns\_detach service removes the ndd structure from the chain of available NS devices.

# **Examples**

The following example illustrates the **ns\_detach** network service:

```
ns detach(nddp);
```

### **Return Values**

Indicates the operation was successful.

ENOENT Indicates the specified *ndd* structure was not found.

**EBUSY** Indicates the network device driver (NDD) is currently in use.

### **Related Information**

The ns attach network service.

# ns\_free Network Service

# **Purpose**

Relinquishes access to a network device.

# **Syntax**

```
#include <sys/ndd.h>
void ns_free (nddp)
       struct ndd * nddp;
```

#### **Parameters**

nddp Specifies the **ndd** structure of the network device that is to be freed from use.

## **Description**

The **ns\_free** network service relinquishes access to a network device. The **ns\_free** network service also decrements the reference count for the specified **ndd** structure. If the reference count becomes 0, the **ns\_free** network service calls the **ndd\_close** subroutine specified in the **ndd** structure.

## **Examples**

The following example illustrates the **ns\_free** network service:

```
struct ndd *nddp
ns free(nddp);
```

### **Files**

net/cdli.c

### **Related Information**

The ns\_alloc network service.

## panic Kernel Service

# **Purpose**

Crashes the system.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
panic ( s)
char *s;
```

#### **Parameter**

s Points to a character string to be written to the error log.

# **Description**

The **panic** kernel service is called when a catastrophic error occurs and the system can no longer continue to operate. The **panic** service performs these two actions:

- Writes the character string pointed to by the s parameter to the error log.
- Performs a system dump.

The system halts after the dump. You should wait for the dump to complete, reboot the system, and then save and analyze the dump.

### **Execution Environment**

The panic kernel service can be called from either the process or interrupt environment.

### **Return Values**

The **panic** kernel service has no return values.

### **Related Information**

RAS Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# pci\_cfgrw Kernel Service

## **Purpose**

Reads and writes PCI bus slot configuration registers.

## **Syntax**

```
#include <sys/mdio.h>
int pci_cfgrw(bid, md, write flag)
int bid;
struct mdio *md;
int write flag;
```

# **Description**

The pci\_cfgrw kernel service provides serialized access to the configuration registers for a PCI bus. To ensure data integrity in a multi-processor environment, a lock is required before accessing the configuration registers. Depending on the value of the write\_flag parameter, a read or write to the configuration register is performed at offset md\_addr for the device identified by md\_sla.

The pci cfgrw kernel service provides for kernel extensions the same services as the MIOPCFGET and MIOPCFPUT ioctls provides for applications. The pci\_cfgrw kernel service can be called from either the process or the interrupt environment.

### **Parameters**

bid Specifies the bus identifier.

md Specifies the address of the mdio structure. The mdio structure contains the following fields:

md\_addr

Starting offset of the configuration register to access (0 to 0xFF for PCI/PCI-X, and 0 to 0xFFF for PCI-E).

md\_data

Pointer to the data buffer.

md size

Number of items of size specified by the *md\_incr* parameter. The maximum size is 256 bytes for PCI/PCI-X, and 4096 for PCI-E.

md\_incr

Access types, MV\_BYTE, MV\_WORD, or MV\_SHORT.

md\_sla Device Number and Function Number.

(Device Number \* 8) + Function.

Set to 1 for write and 0 for read. write\_flag

### **Return Values**

Returns 0 for successful completion.

**ENOMEM** Indicates no memory could be allocated.

**EINVAL** Indicated that the bus, device/function, or size is not valid. **EPERM** 

Indicates that the platform does not allow the requested operation

### **Related Information**

Machine Device Driver in AIX Version 7.1 Technical Reference: Kernel and Subsystems, Volume 2

# pfctlinput Kernel Service

### **Purpose**

Invokes the **ctlinput** function for each configured protocol.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/domain.h>
void pfctlinput ( cmd, sa)
int cmd;
struct sockaddr *sa;
```

### **Parameters**

```
Specifies the command to pass on to protocols.
       Indicates the address of a sockaddr structure that is passed to the protocols.
sa
```

# **Description**

The pfctlinput kernel service searches through the protocol switch table of each configured domain and invokes the protocol ctlinput function if defined. Both the cmd and sa parameters are passed as parameters to the protocol function.

### **Execution Environment**

The **pfctlinput** kernel service can be called from either the process or interrupt environment.

### **Return Values**

The **pfctlinput** service has no return values.

### **Related Information**

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# pffindproto Kernel Service

# **Purpose**

Returns the address of a protocol switch table entry.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/domain.h>
```

```
struct protosw *pffindproto (family, protocol, type)
int family;
int protocol;
int type;
```

### **Parameters**

family Specifies the address family for which to search. Indicates the protocol within the address family. protocol

Specifies the type of socket (for example, SOCK\_RAW). type

# **Description**

The **pffindproto** kernel service first searches the domain switch table for the address family specified by the family parameter. If found, the pffindproto service then searches the protocol switch table for that domain and checks for matches with the type and protocol parameters.

If a match is found, the pffindproto service returns the address of the protocol switch table entry. If the type parameter is set to SOCK RAW, the pffindproto service returns the first entry it finds with protocol equal to 0 and type equal to SOCK RAW.

### **Execution Environment**

The **pffindproto** kernel service can be called from either the process or interrupt environment.

### **Return Values**

The **pffindproto** service returns a null value if a protocol switch table entry was not found for the given search criteria. Upon success, the pffindproto service returns the address of a protocol switch table entry.

# pgsignal Kernel Service

# **Purpose**

Sends a signal to all of the processes in a process group.

# **Syntax**

```
#include <svs/tvpes.h>
#include <sys/errno.h>
void pgsignal (pid, sig)
pid_t pid;
int sig;
```

#### **Parameters**

pid Specifies the process ID of a process in the group of processes to receive the signal.

Specifies the signal to send. sig

## **Description**

The pasignal kernel service sends a signal to each member in the process group to which the process identified by the pid parameter belongs. The pid parameter must be the process identifier of the member of the process group to be sent the signal. The sig parameter specifies which signal to send.

Device drivers can get the value for the pid parameter by using the getpid kernel service. This value is the process identifier for the currently executing process.

The **sigaction** subroutine contains a list of the valid signals.

#### **Execution Environment**

The **pgsignal** kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The **pgsignal** service has no return values.

### **Related Information**

The getpid kernel service, pidsig kernel service.

The **sigaction** subroutine.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# pidsig Kernel Service

# **Purpose**

Sends a signal to a process.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
void pidsig (pid, sig)
pid t pid;
int sig;
```

### **Parameters**

Specifies the process ID of the receiving process. pid

Specifies the signal to send. sig

# **Description**

The pidsig kernel service sends a signal to a process. The pid parameter must be the process identifier of the process to be sent the signal. The sig parameter specifies the signal to send. See the sigaction subroutine for a list of the valid signals.

Device drivers can get the value for the pid parameter by using the getpid kernel service. This value is the process identifier for the currently executing process.

The pidsig kernel service can be called from an interrupt handler execution environment if the process ID is known.

### **Execution Environment**

The **pidsig** kernel service can be called from either the process or interrupt environment.

### **Return Values**

The pidsig service has no return values.

### Related Information

The **getpid** kernel service, **pgsignal** kernel service.

The **sigaction** subroutine.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## pin Kernel Service

## **Purpose**

Pins the address range in the system (kernel) space.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pin.h>
int pin ( addr, length)
caddr_t addr;
int length;
```

#### **Parameters**

Specifies the address of the first byte to pin. addr length Specifies the number of bytes to pin.

# **Description**

The **pin** service pins the real memory pages touched by the address range specified by the addr and length parameters in the system (kernel) address space. It pins the real-memory pages to ensure that page faults do not occur for memory references in this address range. The pin service increments the pin count for each real-memory page. While the pin count is nonzero, the page cannot be paged out of real memory.

The pin routine pins either the entire address range or none of it. Only a limited number of pages can be pinned in the system. If there are not enough unpinned pages in the system, the pin service returns an error code.

**Note:** If the requested range is not aligned on a page boundary, then memory outside this range is also pinned. This is because the operating system pins only whole pages at a time.

The **pin** service can only be called for addresses within the system (kernel) address space. The **xmempin** service should be used for addresses within kernel or user space.

### **Execution Environment**

The **pin** kernel service can be called from the process environment only.

#### **Return Values**

0 Indicates successful completion.

**EINVAL** Indicates that the value of the *length* parameter is negative or 0. Otherwise, the area of memory

beginning at the address of the first byte to pin (the addr parameter) and extending for the number of

bytes specified by the *length* parameter is not defined.

**EIO** Indicates that a permanent I/O error occurred while referencing data.

**ENOMEM** Indicates that the pin service was unable to pin due to insufficient real memory or exceeding the

systemwide pin count.

**ENOSPC** Indicates insufficient file system or paging space.

### **Related Information**

The **xmempin** and **xmemunpin** kernel services.

Understanding Execution Environments and Memory Kernel Services in *AIX*® *Version 7.1 Kernel Extensions and Device Support Programming Concepts.* 

# pin\_context\_stack or unpin\_context\_stack Kernel Service

### **Purpose**

Pins and unpins hidden kernel stack region.

# **Syntax**

#include <sys/pin.h>

kerrno\_t pin\_context\_stack (flags)

 $long\ flags;$ 

kerrno\_t unpin\_context\_stack (flags)

long flags;

### **Parameters**

flags Various flags to the kernel service. Must be set to 0.

# **Description**

Kernel code that pins its system call stack should call this service before the first kernel stack pin and call the **unpin\_context\_stack()** service after the last unpin. These services do not pin or unpin the C execution stack, but instead pin or unpin a hidden stack resource used for the kernel-key support.

### **Execution Environment**

These services must be called in the process environment.

### **Return Values**

Indicates a successful completion.

**ENOMEM PIN CONTEXT STACK** Indicates that the memory is not sufficient to satisfy the request.

ENOSPC PIN CONTEXT STACK EINVAL\_PIN\_CONTEXT\_STACK **EINVAL UNPIN CONTEXT STACK** 

Indicates that the page space is not sufficient. Indicates that the execution environment is not valid. Indicates that the execution environment is not valid. (For example, the service is not in the process environment or the kernel keys are not enabled or the value of the *flag* parameter is not valid.)

#### **Related Information**

The vm\_setseg\_kkey, vm\_protect\_kkey, raschk\_eaddr\_kkey, xmgethkeyset, xmsethkeyset kernel services.

## pincf Kernel Service

## **Purpose**

Manages the list of free character buffers.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
int pincf ( delta)
int delta:
```

### **Parameter**

Specifies the amount by which to change the number of free-pinned character buffers. delta

# **Description**

The pincf service is used to control the size of the list of free-pinned character buffers. A positive value for the delta parameter increases the size of this list, while a negative value decreases the size.

All device drivers that use character blocks need to use the pincf service. These drivers must indicate with a positive delta value the maximum number of character blocks they expect to be using concurrently. Device drivers typically call this service with a positive value when the **ddopen** routine is called. They should call the pincf service with a negative value of the same amount when they no longer need the pinned character blocks. This occurs typically when the **ddclose** routine is called.

### **Execution Environment**

The **pincf** kernel service can be called in the process environment only.

### **Return Values**

The pincf service returns a value representing the amount by which the service changed the number of free-pinned character buffers.

#### **Related Information**

The waitcfree kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# pincode Kernel Service

### **Purpose**

Pins the code and data associated with a loaded object module.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pin.h>

int pincode ( func)
int (*func) ();
```

### **Parameter**

func

Specifies an address used to determine the object module to be pinned. The address is typically that of a function exported by this object module.

# **Description**

The **pincode** service uses the **pin** service to pin the specified object module. The loader entry for the object module is used to determine the size of both the code and data.

### **Execution Environment**

The **pincode** kernel service can be called from the process environment only.

### **Return Values**

Indicates successful completion.

**EINVAL** Indicates that the *func* parameter is not a valid pointer to the function.

**ENOMEM** Indicates that the **pincode** service was unable to pin the module due to insufficient real memory.

When an error occurs, the **pincode** service returns without pinning any pages.

### **Related Information**

The pin kernel service.

Understanding Execution Environments and Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# pio\_assist Kernel Service

# **Purpose**

Provides a standardized programmed I/O exception handling mechanism for all routines performing programmed I/O.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
int pio_assist ( ioparms, iofunc, iorecov)
caddr t ioparms;
int (*iofunc)();
int (*iorecov)();
```

### **Parameters**

ioparms Points to parameters for the I/O routine. iofunc Specifies the I/O routine function pointer.

Specifies the I/O recovery routine function pointer. iorecov

# **Description**

The pio assist kernel service assists in handling exceptions caused by programmed I/O. Use of the pio assist service standardizes the programmed I/O exception handling for all routines performing programmed I/O. The pio assist service is built upon other kernel services that routines access to provide their own exception handling if the pio assist service should not be used.

### Using the pio assist Kernel Service

To use the pio\_assist service, the device handler writer must provide a callable routine that performs the I/O operation. The device handler writer can also optionally provide a routine that can recover and log I/O errors. The mainline device handler code would then call the pio\_assist service with the following parameters:

- A pointer to the parameters needed by the I/O routine
- The function pointer for the routine performing I/O
- A pointer for the I/O recovery routine (or a null pointer, if there is no I/O recovery routine)

If the pointer for the I/O recovery routine is a null character, the iofunc routine is recalled to recover from I/O exceptions. The I/O routine for error retry should only be re-used if the I/O routine can handle being recalled when an error occurs, and if the sequence of I/O instructions can be reissued to recover from typical bus errors.

The *ioparms* parameter points to the parameters needed by the I/O routine. It is passed to the I/O routine when the pio assist service calls the I/O routine. It is also passed to the I/O recovery routine when the I/O recovery routine is invoked by the **pio** assist service. If any of the parameters found in the structure pointed to by the ioparms parameter are modified by the iofunc routine and needed by the iorecov or recalled iofunc routine, they must be declared as volatile.

#### Requirements for Coding the Caller-Provided I/O Routine

The *iofunc* parameter is a function pointer to the routine performing the actual I/O. It is called by the **pio** assist service with the following parameters:

```
int iofunc (ioparms)
caddr t ioparms;
                            /* pointer to parameters */
```

The *ioparms* parameter points to the parameters used by the I/O routine that was provided on the call to the pio\_assist kernel service.

If the pio\_assist kernel service is used with a null pointer to the iorecov I/O recovery routine, the iofunc I/O routine is called to retry all programmed I/O exceptions. This is useful for devices that have I/O operations that can be re-sent without concern for hardware state synchronization problems.

Upon return from the I/O, the return code should be 0 if no error was encountered by the I/O routine itself. If a nonzero return code is presented, it is used as the return code from the pio assist kernel service.

### Requirements for Coding the Caller-Provided I/O Recovery Routine

The iorecov parameter is a function pointer to the device handler's I/O recovery routine. This iorecov routine is responsible for logging error information, if required, and performing the necessary recovery operations to complete the I/O, if possible. This may in fact include calling the original I/O routine. The iorecov routine is called with the following parameters when an exception is detected during execution of the I/O routine:

```
int iorecov (parms, action, infop)
caddr t parms;/* pointer to parameters passed to iofunc*/
int action;
                      /* action indicator */
struct pio except *infop;
                                /* pointer to exception info */
```

The parms parameter points to the parameters used by the I/O routine that were provided on the call to the pio assist service.

The action parameter is an operation code set by the **pio** assist kernel service to one of the following:

**PIO RETRY** Log error and retry I/O operations, if possible. PIO NO RETRY Log error but do not retry the I/O operation.

The pio\_except structure containing the exception information is platform-specific and defined in the /usr/include/sys/except.h file. The fields in this structure define the type of error that occurred, the bus address on which the error occurred, and additional platform-specific information to assist in the handling of the exception.

The iorecov routine should return with a return code of 0 if the exception is a type that the routine can handle. A EXCEPT\_NOT\_HANDLED return code signals that the exception is a type not handled by the iorecov routine. This return code causes the pio\_assist kernel service to invoke the next exception handler on the stack of exception handlers. Any other nonzero return code signals that the *iorecov* routine handled the exception but could not successfully recover the I/O. This error code is returned as the return code from the pio\_assist kernel service.

#### Return Codes by the pio\_assist Kernel Service

The pio assist kernel service returns a return code of 0 if the iofunc I/O routine does not indicate any errors, or if programmed I/O exceptions did occur but were successfully handled by the iorecov I/O recovery routine. If an I/O exception occurs during execution of the *iofunc* or *iorecov* routines and the exception count has not exceeded the maximum value, the iorecov routine is called with an op value of PIO RETRY.

If the number of exceptions that occurred during this operation exceeds the maximum number of retries set by the platform-specific value of PIO\_RETRY\_COUNT, the pio\_assist kernel service calls the iorecov routine with an op value of PIO NO RETRY. This indicates that the I/O operation should not be retried. In this case, the pio\_assist service returns a return code value of EIO indicating failure of the I/O operation.

If the exception is not an I/O-related exception or if the iorecov routine returns with the return code of EXCEPT\_NOT\_HANDLED (indicating that it could not handle the exception), the pio\_assist kernel service does not return to the caller. Instead, it invokes the next exception handler on the stack of exception handlers for the current process or interrupt handler. If no other exception handlers are on the stack, the default exception handler is invoked. The normal action of the default exception handler is to cause a system crash.

#### **Execution Environment**

The pio\_assist kernel service can be called from either the process or interrupt environment.

### **Return Values**

0 Indicates that either no errors were encountered, or PIO errors were encountered and successfully handled. **EIO** Indicates that the I/O operation was unsuccessful because the maximum number of I/O retry operations was

### **Related Information**

Kernel Extension and Device Driver Management Kernel Services, User-Mode Exception Handling, Kernel-Mode Exception Handling in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# **Process State-Change Notification Routine**

## **Purpose**

Allows kernel extensions to be notified of major process and thread state transitions.

## **Syntax**

```
void prochadd_handler ( term, type, id)
struct proch *term;
int type;
long id;
void proch_reg_handler ( term, type, id)
struct prochr *term;
int type;
long id;
```

### **Parameters**

Points to the proch structure used in the prochadd call or to the prochr structure used in the proch\_reg term call.

type

Defines the state change event being reported: process initialization, process termination, process exec, thread initialization, or thread termination. These values are defined in the /usr/include/sys/proc.h file. The values that may be passed as type also depend on how the callout is requested.

Possible prochadd handler type values:

#### PROCH INITIALIZE

Process is initializing.

#### **PROCH TERMINATE**

Process is terminating.

#### PROCH\_EXEC

Process is about to exec a new program.

#### THREAD INITIALIZE

A new thread is created.

#### THREAD TERMINATE

A thread is terminated.

Possible proch\_reg\_handler type values:

#### PROCHR INITIALIZE

Process is initializing.

#### PROCHR TERMINATE

Process is terminating.

#### PROCHR EXEC

Process is about to exec a new program.

#### PROCHR\_THREAD\_INIT

A new thread is created.

#### PROCHR\_THREAD\_TERM

A thread is terminated.

id Defines either the process ID or the thread ID.

# **Description**

The notification callout is set up by using either the prochadd or the proch reg kernel service. If you request the notification using the prochadd kernel service, the callout follows the syntax shown first as prochadd handler. If you request the notification using the proch reg kernel service, the callout follows the syntax shown second as proch reg handler.

For process initialization, the process state-change notification routine is called in the execution environment of a parent process for the initialization of a newly created child process. For kernel processes, the notification routine is called when the initp kernel service is called to complete initialization.

For process termination, the notification routines are called before the kernel handles default termination procedures. The routines must be written so as not to allocate any resources under the terminating process. The notification routine is called under the process image of the terminating process.

### **Related Information**

The prochadd kernel service, prochdel kernel service, proch\_reg kernel service, proch\_unreg kernel service.

Kernel Extension and Device Driver Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# proch\_reg Kernel Service

## **Purpose**

Registers a callout handler.

## **Syntax**

```
#include <sys/proc.h>
int proch_reg(struct prochr *)
```

**Note:** The prochr structure contains the following elements that must be set prior to calling **proch\_reg**:

```
void (* proch handler)(struct prochr *, int, long)
unsigned int int prochr mask
```

### **Parameters**

int prochr\_mask

Specifies the set of kernel events for which a callout is requested. Unlike the old\_style interface, the callout is invoked only for the specified events. This mask is formed by ORing together any of these defined values:

#### PROCHR INITIALIZE

Process created.

#### PROCHR TERMINATE

Process terminated

#### PROCHR\_EXEC

Process has issued the exec system call

#### PROCHR\_THREADINIT

Thread created

#### PROCHR THREADTERM

Thread terminated

Specifies the callout function to be called when specified kernel events occur.

proch\_handler

# **Description**

If the same struct prochr \* is registered more than once, only the most recently specified information is retained in the kernel.

The **struct prochr** \* is not copied to a new location in memory. As a result, if the structure is changed, results are unpredictable. This structure does not need to be pinned.

The primary consideration for the new-style interface is to improve scalability. A lock is only acquired when callouts are made. A summary mask of all currently registered callout event types is maintained. This summary mask is updated every time proch\_reg or proch\_unreg is called, even when registering an identical struct prochr \*. Further, the lock is a complex lock, so once callouts have been registered, there is no lock contention in invoking them because the lock is held read-only.

When a callout to a registered handler function is made, the parameters passed are:

- · a pointer to the registered prochr structure
- · a callout request value to indicate the reason for the callout
- · a thread or process ID

### **Return Values**

On successful completion, the proch\_reg kernel service returns a value of 0. The only error (non-zero) return is from trying to register with a NULL pointer.

### **Execution Environment**

The **proch\_reg** kernel service can be called from the process environment only.

#### Related Information

The proch\_unreg kernel service.

The Process State-Change Notification Routine.

Kernel Extension and Driver Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# proch\_unreg Kernel Service

### **Purpose**

Unregisters a callout handler that was previously registered using the **proch reg** kernel service.

## **Syntax**

#include <sys/proc.h> int proch\_unreg(struct prochr \*old\_prochr);

### **Parameter**

old\_prochr Specifies the address of the **proch** structure to be unregistered.

# **Description**

Unregisters an existing callout handler that was previously registered using the proch\_reg() kernel service.

#### **Return Values**

On successful completion, the proch\_unreg kernel service returns a value of 0. An error (non-zero) return occurs when trying to unregister a handler that is not presently registered.

#### **Execution Environment**

The **proch\_unreg** kernel service can be called from the process environment only.

#### Related Information

The proch reg kernel service.

Kernel Extension and Driver Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# prochadd Kernel Service

# **Purpose**

Adds a system-wide process state-change notification routine.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/proc.h>
void prochadd ( term)
struct proch *term;
```

#### **Parameters**

term

Points to a proch structure containing a notification routine to be added from the chain of systemwide notification routines.

## **Description**

The prochadd kernel service allows kernel extensions to register for notification of major process state transitions. The **prochadd** service allows the caller to be notified when a process:

- · Has just been created.
- · Is about to be terminated.
- Is executing a new program.

The complete list of callouts is:

Callout Description PROCH\_INITIALIZE Process (pid) created (initp, kforkx) PROCH\_TERMINATE Process (pid) terminated (kexitx) PROCH\_EXEC Process (pid) executing (execvex) THREAD INITIALIZE Thread (tid) created (kforkx, thread\_create) THREAD\_TERMINATE Thread (tid) created (kexitx, thread\_terminate)

The prochadd service is typically used to allow recovery or reassignment of resources when processes undergo major state changes.

The caller should allocate a **proch** structure and update the proch.handler field with the entry point of a caller-supplied notification routine before calling the **prochadd** kernel service. This notification routine is called once for each process in the system undergoing a major state change.

The **proch** structure has the following form:

```
struct proch
        struct proch *next
                               *handler ();
        void
}
```

#### **Execution Environment**

The **prochadd** kernel service can be called from the process environment only.

### **Related Information**

The prochdel kernel service.

The Process State-Change Notification Routine.

Kernel Extension and Driver Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# prochdel Kernel Service

## **Purpose**

Deletes a process state change notification routine.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/proc.h>

void prochdel ( term)
struct proch *term;
```

### **Parameter**

term

Points to a **proch** structure containing a notification routine to be removed from the chain of system-wide notification routines. This structure was previously registered by using the **prochadd** kernel service.

# **Description**

The **prochdel** kernel service removes a process change notification routine from the chain of system-wide notification routines. The registered notification routine defined by the handler field in the **proch** structure is no longer to be called by the kernel when major process state changes occur.

If the **proch** structure pointed to by the *term* parameter is not found in the chain of structures, the **prochdel** service performs no operation.

### **Execution Environment**

The prochdel kernel service can be called from the process environment only.

#### **Related Information**

The prochadd kernel service.

The Process State-Change Notification Routine.

Kernel Extension and Driver Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# probe or kprobe Kernel Service

# **Purpose**

Logs errors with symptom strings.

# Library (for probe)

Run-time Services Library.

# **Syntax**

#include <sys/probe.h>
or

```
#include <sys/sysprobe.h>
int probe ( probe p)
probe t *probe p
int kprobe (probe_p)
probe_t *probe p
```

## **Description**

The probe subroutine logs an entry to the error log. The entry consists of an error log entry as defined in the errlog subroutine and the err\_rec.h header file, and a symptom string.

The **probe** subroutine is called from an application, while **kprobe** is called from the Kernel and Kernel extensions. Both probe and kprobe have the same interfaces, except for return codes.

IBM® software should use the sys/sysprobe.h header file while non-IBM® programs should include the sys/probe.h file. This is because IBM® symptom strings must conform to different rules than non-IBM® strings. It also tells any electronic support application whether or not to route the symptom string to IBM® s Retain database.

#### **Parameters**

probe\_p

is a pointer to the data structure which contains the pointer and length of the error record, and the data for the probe. The error record is described under the errlog subroutine and defined in err\_rec.h.

The first word of the structure is a magic number to identify this version of the structure. The magic number should be set to PROBE MAGIC.

Note: PROBE MAGIC is different between probe.h and sysprobe.h to distinguish an IBM® symptom string from a non-IBM® string.

The probe data consists of flags which control probe handling, the number of symptom string keywords, followed by an array consisting of one element for each keyword.

# **Flags**

**SSNOSEND** 

indicates this symptom string shouldn't be forwarded to automatic problem opening facilities. An example where **SSNOSEND** should be used is in symptom data used for debugging purposes.

nsskwd

This gives the number of keywords specified (i.e.), the number of elements in the sskwds array.

#### sskwds

This is an array of keyword/value pairs. The keywords and their values are in the following table. The I/S value indicates whether the keyword and value are informational or are part of the logged symptom string. The number in parenthesis indicates, where applicable, the maximum string length.

keyword	I/S	value	type	Description
SSKWD_LONGNAME	I	char *	(30)	Product's long name
SSKWD_OWNER	I	char *	(16)	Product's owner
SSKWD_PIDS	S	char *	(11)	<pre>product id.(required for IBM symptom strings)</pre>
SSKWD_LVLS	S	char *	(5)	product level (required for IBM symptom strings)
SSKWD APPLID	I	char *	(8)	application id.
SSKWD_PCSS	S	char *	(8)	probe id (required for all symptom strings)
SSKWD_DESC	I	char *	(80)	problem description
SSKWD_SEV	I	int		severity from 1 (highest) to 4 (lowest). 3 is the default.
SSKWD_AB	S	char *	(5)	abend code
SSKWD_ADRS	S	void *		address. If used at all, this should be a relative address.
SSKWD_DEVS	S	char *	(6)	Device type
SSKWD_FLDS	S	char *	(9)	arbitrary character string. This is usually a field name and the SSKWD VALUE keyword specifies the value.
SSKWD_MS	S	char *	(11)	Message number
SSKWD OPCS	S	char *	(8)	OP code
SSKWD OVS	S	char *	(9)	overwritten storage
SSKWD_PRCS	S S			unsigned long return code
SSKWD_REGS	S	char *	(4)	Register name (e.g.) GR15 or LR unsigned long Value
SSKWD VALU	S			
SSKWD_RIDS	S	char *	(8)	resource or module id.
SSKWD_SIG	S.	int		Signal number
SSKWD SN	S	char *	(7)	Serial Number
SSKWD_SRN	S	char *	(9)	Service Req. Number If specified, and no error is logged, a hardware error is assumed.
SSKWD_WS	S	char *	(10)	Coded wait

Note: The SSKWD PCCS value is always required. This is the probe id. Additionally, for IBM® symptom strings, the SSKWD\_PIDS and SSKWD\_LVLS keywords are also required

If either the erecp or erecl fields in the probe rec structure is 0 then no error logging record is being passed, and one of the default templates for symptom strings is used. The default template indicating a software error is used unless the SSKWD\_SRN keyword is specified. If it is, the error is assumed to be a hardware error. If you don't want to log your own error with a symptom string, and you want to have a hardware error, and don't want to use the SSKWD\_SRN value, then you can supply an error log record using the error identifier of ERRID\_HARDWARE\_SYMPTOM, see the /usr/include/sys/errids.h file.

# **Return Values for probe Subroutine**

Successful

Error. The errno variable is set to Indicates an invalid parameter **EINVAL EFAULT** Indicates an invalid address

# **Return Values for kprobe Kernal Service**

Successful

**EINVAL** Indicates an invalid parameter

### **Execution Environment**

**probe** is executed from the application environment.

kprobe is executed from the Kernel and Kernel extensions. Currently, kprobe must not be called with interrupts disabled.

### **Files**

/usr/include/sys/probe.h

Contains parameter definition.

### **Related Information**

Error Logging Overview.

The **errlog** subroutines.

The errsave or errlast subroutines.

# purblk Kernel Service

## **Purpose**

Purges the specified block from the buffer cache.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
void purblk ( dev, blkno)
dev t dev;
daddr_t blkno;
```

### **Parameters**

Specifies the device containing the block to be purged. dev

blkno Specifies the block to be purged.

# **Description**

The purblk kernel service purges (that is, makes unreclaimable by marking the block with a value of STALE) the specified block from the buffer cache.

### **Execution Environment**

The purblk kernel service can be called from the process environment only.

#### Return Values

The purblk service has no return values.

#### **Related Information**

The brelse kernel service, geteblk kernel service.

Block I/O Buffer Cache Kernel Services: Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# putc Kernel Service

## **Purpose**

Places a character at the end of a character list.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>

int putc ( c, header)
char c;
struct clist *header;
```

### **Parameters**

c Specifies the character to place on the character list.

header Specifies the address of the **clist** structure that describes the character list.

## **Description**

**Attention:** The caller of the **putc** service must ensure that the character list is pinned. This includes the **clist** header and all the **cblock** character buffers. Character blocks acquired from the **getcf** service are also pinned. Otherwise, the system may crash.

The **putc** kernel service puts the character specified by the *c* parameter at the end of the character list pointed to by the *header* parameter.

If the **putc** service indicates that there are no more buffers available, the **waitcfree** service can be used to wait until a character block is available.

### **Execution Environment**

The putc kernel service can be called from either the process or interrupt environment.

#### **Return Values**

- **0** Indicates successful completion.
- -1 Indicates that the character list is full and no more buffers are available.

### **Related Information**

The **getcb** kernel service, **getcf** kernel service, **pincf** kernel service, **putcf** kernel service, **putcf** kernel service, **putcf** kernel service, **putcf** kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# putcb Kernel Service

# **Purpose**

Places a character buffer at the end of a character list.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
void putcb ( p, header)
struct cblock *p;
struct clist *header;
```

#### **Parameters**

Specifies the address of the character buffer to place on the character list. Specifies the address of the clist structure that describes the character list. header

## **Description**

Attention: The caller of the putch service must ensure that the character list is pinned. This includes the clist header and all the cblock character buffers. Character blocks acquired from the getcf service are pinned. Otherwise, the system may crash.

The **putcb** kernel service places the character buffer pointed to by the p parameter on the end of the character list specified by the header parameter. Before calling the putch service, you must load this new buffer with characters and set the c first and c last fields in the cblock structure. The p parameter is the address returned by either the getcf or the getcb service.

#### **Execution Environment**

The **putcb** kernel service can be called from either the process or interrupt environment.

#### **Return Values**

- 0 Indicates successful completion.
- -1 Indicates that the character list is full and no more buffers are available.

### **Related Information**

The getcb kernel service, getcf kernel service, pincf kernel service, putcf kernel service, putcfl kernel service, waitcfree kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# putcbp Kernel Service

# **Purpose**

Places several characters at the end of a character list.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <cblock.h>

```
int putcbp ( header,  source,  n)
struct clist *header;
char *source;
int n;
```

#### **Parameters**

header Specifies the address of the **clist** structure that describes the character list.

source Specifies the address from which characters are read to be placed on the character list.

n Specifies the number of characters to be placed on the character list.

## **Description**

**Attention:** The caller of the **putcbp** service must ensure that the character list is pinned. This includes the **clist** header and all of the **cblock** character buffers. Character blocks acquired from the **getcf** service are pinned. Otherwise, the system may crash.

The **putcbp** kernel service operates on the characters specified by the *n* parameter starting at the address pointed to by the *source* parameter. This service places these characters at the end of the character list pointed to by the *header* parameter. The **putcbp** service then returns the number of characters added to the character list. If the character list is full and no more buffers are available, the **putcbp** service returns a 0. Otherwise, it returns the number of characters written.

### **Execution Environment**

The putcbp kernel service can be called from either the process or interrupt environment.

### **Return Values**

The **putchp** service returns the number of characters written or a value of 0 if the character list is full, and no more buffers are available.

#### **Related Information**

The **getcb** kernel service, **getcf** kernel service, **pincf** kernel service, **putcf** kernel service, **p** 

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# putcf Kernel Service

# **Purpose**

Frees a specified buffer.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>

void putcf ( p)
struct cblock *p;
```

#### **Parameter**

p Identifies which character buffer to free.

## **Description**

The **putcf** kernel service unpins the indicated character buffer.

The putcf service returns the specified buffer to the list of free character buffers.

### **Execution Environment**

The **putcf** kernel service can be called from either the process or interrupt environment.

### **Return Values**

The putcf service has no return values.

### **Related Information**

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## putcfl Kernel Service

## **Purpose**

Frees the specified list of buffers.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
void putcfl ( header)
struct clist *header;
```

#### **Parameter**

header Identifies which list of character buffers to free.

# **Description**

The putcfl kernel service returns the specified list of buffers to the list of free character buffers. The putcfl service unpins the indicated character buffer.

Note: The caller of the putcfl service must ensure that the header and clist structure are pinned.

#### **Execution Environment**

The putcfl kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The putcfl service has no return values.

#### **Related Information**

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# putcx Kernel Service

## **Purpose**

Places a character on a character list.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/cblock.h>
int putcx ( c, header)
char c;
struct clist *header;
```

### **Parameters**

Specifies the character to place at the front of the character list.

header Specifies the address of the clist structure that describes the character list.

## **Description**

The **putcx** kernel service puts the character specified by the c parameter at the front of the character list pointed to by the header parameter. The putcx service is identical to the putc service, except that it puts the character at the front of the list instead of at the end.

If the putcx service indicates that there are no more buffers available, the waitcfree service can be used to wait until a character buffer is available.

Note: The caller of the putcx service must ensure that the character list is pinned. This includes the clist header and all the cblock character buffers. Character blocks acquired from the getcf service are pinned.

### **Execution Environment**

The **putcx** kernel service can be called from either the process or interrupt environment.

## **Return Values**

- Indicates successful completion.
- -1 Indicates that the character list is full and no more buffers are available.

### **Related Information**

The getcb kernel service, getcf kernel service, pincf kernel service, putcf kernel service, putcfl kernel service, waitcfree kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# query\_proc\_info Kernel Service

# **Purpose**

Returns specific information about the current process or thread.

## **Syntax**

```
#include <sys/encap.h>
```

```
int query proc info (type)
int type;
```

### **Parameters**

type

Specifies the type of process or thread information requested. The type parameter can be one of the following values:

QPI\_XPG\_SUS\_ENV

Queries whether the calling process has SPEC 1170 environment active.

**QTI FUNNELLED** 

Queries whether the current thread is funneled.

## **Description**

The query\_proc\_info kernel service returns information about the current process or thread.

When called with the value QPI XPG SUS ENV as the type parameter, it returns TRUE (1) when the process has SPEC 1170 active, that is, the process was issued with the environment variable XPG SUS ENV defined. Otherwise, the routine returns FALSE (0). When called with the value QTI FUNNELLED as the type parameter, the query proc info kernel service returns TRUE (1) if the current thread has been funneled. Otherwise, the routine returns FALSE (0).

### **Execution Environment**

The query proc info kernel service can be called from either the process or interrupt environment.

### **Return Values**

1 True False.

# **RAS\_BLOCK\_NULL Exported Data Structure**

# **Purpose**

Allows for the silent failure of ras\_register calls due to memory allocation errors.

# **Syntax**

#include <sys/ras.h>

extern const ras block t RAS BLOCK NULL

# **Description**

The RAS BLOCK NULL data structure allows components to go through their normal code paths when they receive an ENOMEM error from the ras register kernel service. The presence of this data structure does not need to be explicitly checked by callers of RAS functions. All RAS domain functions (such as Component Tracing) are disabled with this control block.

The ras\_register and ras\_unregister exported kernel services.

The ras\_control exported kernel service.

The ras\_customize exported kernel service.

The CT\_HOOKx and CT\_GEN macros.

The **CT\_TRCON** macro.

### ras control Exported Kernel Service

### **Purpose**

Controls component RAS characteristics.

# **Syntax**

```
#include <sys/ras.h>
kerrno t ras control (
ras_block_t ras_blk,
ras_cmd_t command,
void * arg,
long argsize);
```

# **Description**

The ras control kernel service passes a command to the callback for the component referenced by the ras\_blk parameter. If the ras\_blk parameter is not known, use the ras\_path\_control call.

Note: During the ras control process, callbacks to the registrant of the component might be initiated for changes that the RAS infrastructure makes to the component. The registrant should be aware of this for locking purposes (for instance, the registrant should not hold any locks that the callback needs).

If the ras blk input parameter has a value of RAS BLOCK NULL, the ras control kernel service returns without errors and takes no action.

#### **Parameters**

ras\_blk The target control block pointer.

Command passed to the callback. Commands are specific to a given RAS domain, command

such as Component Trace.

arg Optional argument for the command. argsize Size of the argument, if a buffer or structure.

#### **Execution Environment**

The calling environment of the ras\_control kernel service varies by individual command. The calling environment of a particular command is documented with the command itself.

#### **Return Values**

The ras\_control kernel service returns 0 for success and a non-zero error code for failure.

Component Trace Facility in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

The ras\_callback registered callback.

The ras\_register and ras\_unregister exported kernel services.

The ras\_customize exported kernel service.

The **ras** path **control** exported kernel service.

The RAS\_BLOCK\_NULL data structure.

### ras customize Exported Kernel Service

### **Purpose**

Loads persistent customized properties for a RAS control block.

# **Syntax**

#include <sys/ras.h>

kerrno\_t ras\_customize (ras\_block\_t ras\_blk);

# **Description**

The ras customize kernel service checks for, and applies persistent customized properties for a given ras blk parameter. After applying any persistent properties, the ras customize kernel service puts the ras\_blk parameter in a usable state. Registration is not complete without a call to the ras\_customize kernel service.

Note: During the ras customize process, callbacks to the registrant might be initiated for changes that the RAS infrastructure makes to the component. The registrant should be aware of this for locking and initialization purposes (for example, the registrant should not be holding any locks that the callback needs, and the private data for the callback should be initialized before ras\_customize is called).

If the ras blk input parameter has a value of RAS BLOCK NULL, the ras customize kernel service returns without errors and takes no action.

### **Parameters**

ras\_blk

The control block to act on. Must be previously allocated by the ras\_register kernel service.

### **Execution Environment**

The ras\_customize kernel service must be called from the process environment.

### **Return Values**

Successful. n non-zero Unsuccessful.

Component Trace Facility in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

The ras\_callback registered callback.

The ras\_register and ras\_unregister exported kernel services.

The ras\_control exported kernel service.

The RAS BLOCK NULL data structure.

### ras path control Exported Kernel Services

### **Purpose**

Controls component RAS characteristics.

# **Syntax**

```
#include <sys/ras.h>
kerrno_t ras_path_control (
char * path,
ras cmd t command,
void * arg,
long argsize);
```

# **Description**

The ras\_path\_control kernel service passes a command to the RAS component specified by the path parameter.

Note: During the ras path control process, callbacks to the registrant of the component might be initiated for changes that the RAS infrastructure makes to the component. The registrant should be aware of this for locking purposes (for instance, the registrant should not be holding any locks the callback needs).

#### **Parameters**

path The pathname of the component to receive the *command* parameter.

Command passed to the callback. Commands are specific to a given RAS domain, command

such as Component Trace.

Optional argument for the command. arg Size of the argument, if a buffer or structure. argsize

#### **Execution Environment**

The calling environment of the ras\_path\_control kernel service varies by individual command. The calling environment of a particular command is documented with the command itself.

### **Return Values**

Successful. non-zero Unsuccessful.

Component Trace Facility in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

The ras control exported kernel service.

The ras\_register and ras\_unregister exported kernel services.

The ras\_customize exported kernel service.

# ras register and ras unregister Exported Kernel Services

### **Purpose**

Registers and unregisters a RAS component.

# **Syntax**

```
#include <sys/ras.h>
kerrno t ras register (
ras block t * rasbp,
char * name,
ras block t parent,
ras_type_t typesubtype,
char * desc,
long flags,
ras callback t ras callback,
void * private data);
kerrno_t ras_unregister (ras_block_t ras_blk);
```

# **Description**

The ras register kernel service and the ras unregister kernel service register and unregister RAS handlers which are invoked by the kernel when the system needs to communicate various RAS commands to each component.

The ras register kernel service registers a component with the given name under the parent provided. If the parent is NULL, the ras register kernel service registers name as a base component, but the typesubtype parameter must be provided. The name parameter specifies the name for the subcomponent or base component (it is not a full component path). The flags field is used to specify what aspects of RAS the component understands. The ras\_callback is the mechanism by which the RAS subsystem communicates various commands to the component, depending on what aspects of RAS the component understands. The *desc* parameter provides a short description for the component as a service aid.

The ras register kernel service allocates a ras block t member and returns the control block for the component through the rasbp argument. This control block can be used in ras\_control calls and further ras\_register calls (to allocate children, for instance).

If the registration fails due to the system being out of memory, the value of the rasbp argument is set to RAS\_BLOCK\_NULL. All RAS functions for this component are disabled. RAS kernel services accept RAS\_BLOCK\_NULL control blocks but take no action. If the control block is set to RAS\_BLOCK\_NULLRAS, domain related functions (such as the CT\_HOOKx and CT\_GEN macros) run correctly but take no action. This action allows the ENOMEM type failures from the ras register kernel service to be safely ignored. The value of the rasbp argument for all other types of errors is undefined.

The ras unregister kernel service unregisters a component previously registered with the ras register kernel service. The *ras blk* parameter should have no further children.

### **Parameters**

flags

The newly allocated ras\_block\_t member. rasbp

name The name of the component, not its full pathname. Individual node names are limited

> to the number of characters specified by the value of the RAS\_NAME\_MAX parameter (including the terminating NULL character). The full component path (the concatenated names of a child component and all of its ancestors) is limited to the number of characters specified by the value of the RAS\_PATH\_MAX parameter (including the terminating NULL character). The ras\_register kernel service reconstructs the full component path and rejects registrations for components whose full path exceeds the value of the RAS\_PATH\_MAX parameter. Node names are

restricted to the character set "A-Z", "a-z", "0-9" and "\_".

An optional pointer to the parent component or NULL if none. parent

If parent is NULL, mandatory parameter is used to categorize the component. The top typesubtype

> 16-bits of the lower word of this field are the type, and the bottom 16-bits are the subtype. The typesubtype is a ras\_type\_t member, which is an enum. See the sys/ras\_base.h file for a description of the types available. If parent is non-NULL, this

parameter is required to be the value of the RAS\_TYPE\_CHILD parameter.

A short description string for the component. The desc string is limited to the number desc

of characters specified by the value of the RAS\_DESC\_MAX parameter (including the terminating null). The desc string has no character set restriction. Any static elements of the string should be in U.S. English, but dynamic elements have no restriction. Indicates what type of RAS systems this component is aware of. Valid choices are the

followina:

RASF\_TRACE\_AWARE: Component is Component Trace aware.

• RASF\_ERROR\_AWARE: Component is Error Checking aware.

These flags are defined in the sys/ras.h file.

ras\_callback A function pointer provided by the registrant and called by the framework each time

an external event modifies a property of the component. See the ras callback

interface specification.

An optional pointer to a component private memory area passed to the ras\_callback private\_data

function upon callback.

The control block to remove. ras blk

#### **Execution Environment**

Both the ras register kernel service and the ras unregister kernel service must be called from the process environment.

#### **Return Values**

The following are the return values of the **ras register** kernel service.

Successful. non-zero Unsuccessful.

The following are the return values of the **ras unregister** kernel service.

Successful. 0 non-zero Unsuccessful.

Component Trace Facility in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

The **ras\_callback** registered callback.

The ras\_customize exported kernel service.

The ras\_control exported kernel service.

The RAS BLOCK NULL data structure.

### ras\_ret\_query\_parms Kernel Service

### **Purpose**

Returns callback parameters in the ras\_query\_parms structure.

# **Syntax**

```
#include <sys/ras.h>
kerrno_t ras_ret_query_parms (retp, fmtstr, numstrings, descr)
ras_query_parms_t *retp;
char *fmtstr;
int numstrings;
char *descr[];
```

### **Parameters**

retp Points to the ras\_query\_parms\_t data item to be filled in.

fmtstr This is a format specifier. It has the following form:

spec-list

or

kywd=spec-list kywd=spec-list ...

Where the *spec-list* variable is of the form: *spec,spec,...* . The *spec* variable must be %x, %xx, %d, %dd, %s, or %ss. If the characters x, d, or s are doubled, for example, %xx, this indicates that multiple values are allowed.

The following are some valid fmtstr values:

%x One hexidecimal value.

%x,%d One hexadecimal and one decimal value.

%xx Multiple hexadecimal values.

k1=%x,%d k2=%dd

Keyword k1 takes one hexadecimal value and one decimal value. Keyword k2 takes multiple decimal values.

numstrings Specifies the number of strings in the descr string array. The value must be at least 1.

descr

Specifies the component and parameters. There must be at least one string. The first string describes the component's function. If the component takes positional parameters, the following string(s) describe those. If keyword parameters are supplied, each keyword must have a corresponding descr string in the array describing that keyword.

The ras\_ret\_query\_parms kernel service does not return an error if the number of the descr strings does not match the format string. Instead, either the last keywords do not have help text, or the excess help strings are simply displayed.

# **Description**

The ras\_ret\_query\_parms kernel service can be used by a callback to aid in filling in the ras\_query\_parms\_t structure when it receives the RASC\_QUERY\_PARMS call. This function formats the help text and places it into the ras\_query\_parms\_t structure. If there is insufficient space for the help text in the provided ras\_query\_parms\_t item, it returns ENOMEM\_RASC\_CONTROL\_QUERYPARMS. The callback then just returns this error code.

The help text provided must follow the following conventions:

```
component - first line of description
component:parameters - parameter(s) description
```

or

```
component - first line of description
component: kywd1 = parms - kywd1: parms \ description
component:kywd2=parms - kywd2:parms description
```

### **Execution Environment**

The ras\_ret\_query\_parms kernel service can be called from the process environment only.

#### Return Values

EINVAL\_RAS\_CONTROL\_QUERYPARMS

EFAULT\_RAS\_CONTROL\_QUERYPARMS

**ENOMEM\_RAS\_CONTROL\_QUERYPARMS** 

Indicates a successful completion.

Indicates that one or more parameters was not valid. Indicates that one or more parameter addresses was not

Indicates that the rqp\_text size was not large enough.

### Related Information

The **dmp\_compspec** kernel service.

# raschk\_eaddr\_hkeyset Kernel Service

# **Purpose**

Checks if an effective address can be referenced with a hardware keyset.

```
#include <sys/raschk.h>
#include <sys/skeys.h>
#include <sys/kerrno.h>
```

kerrno t rashchk eaddr hkeyset (eaddr, hset, flags) void \* eaddr; hkeyset\_t hset; unsigned long flags;

### **Parameters**

eaddr Effective address to validate. Only one byte is checked.

hset Hardware keyset to validate against. flags The following flags are defined:

RCHK EHK NOFAULT

No page faults are permitted while performing this check.

RCHK EHK NOPAGEIN

No page in is performed during this check.

RCHK EHK READ

Validates for read access.

RCHK\_EHK\_WRITE

Validates for write access.

### **Description**

The raschk\_eaddr\_hkeyset kernel service performs an advisory runtime check to determine if an effective address can be referenced with a hardware keyset.

Read and write access checks are independently specified in the flags field. A check for read and write access requires both flags to be set.

#### **Execution Environment**

The raschk\_eaddr\_hkeyset kernel service can be called from the process or interrupt environment.

### **Return Values**

Successful.

EFAULT\_RASCHK\_EADDR\_HKEYSET Operation failed because a page in or page fault was not

allowed.

EFAULT RASCHK EADDR HKEYSET PROT The address failed the protection check.

EINVAL\_RASCHK\_EADDR\_HKEYSET The address to validate was determined to be invalid, or neither READ nor WRITE checking was requested.

#### **Related Information**

The raschk\_eaddr\_kkey kernel service.

# raschk\_eaddr\_kkey Kernel Service

# **Purpose**

Checks if an effective address can be referenced with a kernel-key.

# **Syntax**

#include <sys/raschk.h> #include <sys/kerrno.h>

```
kerrno t raschk eaddr kkey (eaddr, kkey, flags)
void * eaddr;
kkey_t kkey;
unsigned long flags;
```

#### **Parameters**

eaddr Effective address to validate. Only one byte is checked.

kkey Kernel-key to check.

flags The following flags are defined:

RCHK EK NOFAULT

No page faults of any kind are permitted while performing this check.

RCHK EK NOPAGEIN

No page in will be performed during this check.

### **Description**

The raschk\_eaddr\_kkey kernel service performs an advisory runtime check to determine if an effective address can be referenced with a kernel-key. Note that read/write attributes are not maintained at a page granularity. This service only checks if the kernel-key assigned to an effective address matches the kkey value.

### **Execution Environment**

The raschk\_eaddr\_kkey kernel service can be called from the process or interrupt environment.

### **Return Values**

Successful.

EFAULT\_RASCHK\_EADDR\_KKEY Operation cannot be performed because a page in or page

fault was not allowed.

EINVAL RASCHK EADDR KKEY The address to validate was determined to be invalid.

EINVAL\_RASCHK\_EADDR\_KKEY\_PROT The address failed the protection check.

### **Related Information**

The raschk\_eaddr\_hkeyset kernel service.

# raw\_input Kernel Service

# **Purpose**

Builds a **raw header** structure for a packet and sends both to the raw protocol handler.

```
#include <sys/types.h>
#include <sys/errno.h>
void raw_input (m0, proto, src, dst)
struct mbuf * m0;
struct sockproto * proto;
struct sockaddr * src;
struct sockaddr * dst;
```

### **Parameters**

m0	Specifies	the address	of an	mbuf structure	containing input data.
1110	ODECINES	liic audicss	ui aii	IIIDUI SHUCKUIC	Containing input data.

proto Specifies the protocol definition of data.

Identifies the **sockaddr** structure indicating where data is from. src dst Identifies the **sockaddr** structure indicating the destination of the data.

### **Description**

The raw input kernel service accepts an input packet, builds a raw header structure (as defined in the /usr/include/net/raw cb.h file), and passes both on to the raw protocol input handler.

### **Execution Environment**

The raw\_input kernel service can be called from either the process or interrupt environment.

### **Return Values**

The raw input service has no return values.

### **Related Information**

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### raw\_usrreq Kernel Service

# **Purpose**

Implements user requests for raw protocols.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
void raw_usrreq (so, req, m, nam, control)
struct socket * so;
int req;
struct mbuf * m;
struct mbuf * nam;
struct mbuf * control:
```

### **Parameters**

Identifies the address of a raw socket. so Specifies the request command. rea

Specifies the address of an mbuf structure containing data.

nam Specifies the address of an **mbuf** structure containing the **sockaddr** structure.

control This parameter should be set to a null value.

# **Description**

The **raw\_usrreq** kernel service implements user requests for the raw protocol.

The **raw\_usrreq** service supports the following commands:

Command Description

PRU\_ABORT Aborts (fast DISCONNECT, DETACH).

PRU\_ACCEPT Accepts connection from peer.
PRU\_ATTACH Attaches protocol to up.
PRU\_BIND Binds socket to address.
PRU\_CONNECT Establishes connection to peer.

PRU\_CONNECT2 Connects two sockets.

PRU\_CONTROL Controls operations on protocol.

PRU\_DETACH Detaches protocol from up.

PRU\_DISCONNECT Disconnects from peer.

PRU\_LISTEN Listens for connection.

PRU\_PEERADDR Fetches peer's address.

PRU\_RCVD Have taken data; more room now.

**PRU\_RCVOOB** Retrieves out of band data.

PRU SEND Sends this data.

PRU\_SENDOOB Sends out of band data.
PRU\_SENSE Returns status into m.
PRU\_SOCKADDR Fetches socket's address.
PRU\_SHUTDOWN Will not send any more data.

Any unrecognized command causes the panic kernel service to be called.

### **Execution Environment**

The raw\_userreq kernel service can be called from either the process or interrupt environment.

### **Return Values**

**EOPNOTSUPP** Indicates an unsupported command.

**EINVAL** Indicates a parameter error.

**EACCES** Indicates insufficient authority to support the **PRU\_ATTACH** command.

**ENOTCONN** Indicates an attempt to detach when not attached.

**EISCONN** Indicates that the caller tried to connect while already connected.

### **Related Information**

The panic kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# reconfig\_register, reconfig\_register\_ext, reconfig\_unregister, or reconfig\_complete, reconfig\_register\_list Kernel Service

# **Purpose**

Register and unregister reconfiguration handlers.

```
#include <sys/dr.h>
int reconfig_register (handler, actions, h_arg, h_token, name)
int (*handler)(void *event, void *h_arg, int req, void *resource_info);
int actions;
void *h arg;
```

```
ulong *h token;
char *name;
int reconfig_register_ext (handler, actions, h_arg, h_token, name)
int (*handler) (void *event, void *h arg, unsigned long long req, void *resource info);
unsigned long long actions;
void *h arg;
ulong *h token;
char *name;
int reconfig unregister (h token)
ulong h token;
void reconfig_complete (event, rc)
void *event;
int rc;
int reconfig_register_list (handler, event list, list size, h arg, h token, name)
int (*handler)(void *event, void *h_arg, dr_kevent_t event_in_prog, void *resource_info);
dr_kevent_t event_list[];
size_t list size;
void *h arg;
ulong *h token;
char *name;
```

# **Description**

The reconfig\_register, reconfig\_register\_ext, reconfig\_register\_list and reconfig\_unregister kernel services register and unregister reconfiguration handlers, which are invoked by the kernel both before and after DLPAR operations depending on the set of events specified by the kernel extension when registering.

Starting with AIX® 6.1 with 6100-02, all future kernel extensions use the reconfig register list kernel service when registering for DLPAR operations. The reconfig\_register\_list kernel service supports previous and new DLPAR operations. The reconfig register or reconfig register ext kernel services will no longer support all future DLPAR operations.

The **reconfig** complete kernel service is used to indicate that the request has completed. If a kernel extension expects that the operation is likely to take a long time (several seconds), the handler must return **DR WAIT** to the caller, but proceed with the request asynchronously. In this case, the handler must indicate that it has completed the request by invoking the reconfig complete kernel service.

### **Parameters**

actions

Allows the kernel extension to specify which of the following events require notification:

- DR\_PMIG\_CHECK
- DR\_PMIG\_PRE
- DR\_PMIG\_POST
- DR\_PMIG\_POST\_ERROR
- DR\_CAP\_ADD\_CHECK
- DR CAP ADD PRE
- DR\_CAP\_ADD\_POST
- DR\_CAP\_ADD\_POST\_ERROR
- DR\_CAP\_REMOVE\_CHECK
- DR\_CAP\_REMOVE\_PRE
- DR\_CAP\_REMOVE\_POST
- DR\_CAP\_REMOVE\_POST\_ERROR
- DR\_CPU\_ADD\_CHECK
- DR\_CPU\_ADD\_PRE
- DR\_CPU\_ADD\_POST
- DR\_CPU\_ADD\_POST\_ERROR
- DR\_CPU\_REMOVE\_CHECK
- DR\_CPU\_REMOVE\_PRE
- DR\_CPU\_REMOVE\_POST
- DR\_CPU\_REMOVE\_POST\_ERROR
- DR\_MEM\_ADD\_CHECK
- DR MEM ADD OP POST
- DR\_MEM\_ADD\_PRE
- DR\_MEM\_ADD\_POST
- DR\_MEM\_ADD\_POST\_ERROR
- DR\_MEM\_REMOVE\_CHECK
- DR\_MEM\_REMOVE\_OP\_POST
- DR\_MEM\_REMOVE\_OP\_PRE
- DR\_MEM\_REMOVE\_PRE
- DR\_MEM\_REMOVE\_POST
- DR\_MEM\_REMOVE\_POST\_ERROR

event

Passed to the handler and intended to be used only when calling the **reconfig\_complete** kernel service.

event\_list handler Specifies which events require notification. For the supported values, see the **dr.h** file.

ler Specifies the kernel extension function to be invoked.

h arg

Specified by the kernel extension, remembered by the kernel along with the function descriptor for the handler, and passed to the handler when it is invoked. It is not used directly by the kernel, but is intended to support kernel extensions that manage multiple adapter instances.

This parameter points to an adapter control block.

h\_token

An output parameter that is used when unregistering the handler.

list\_size

Specifies the memory size of the event\_list array.

name

Provided for information purposes and may be included within an error log entry, if the driver returns an error. It is provided by the kernel extension and must be limited to 15 ASCII

characters.

rc

Can be set to DR\_FAIL or DR\_SUCCESS.

resource\_info

Identifies the resource specific information for the current DLPAR request. If the request is cpu based, the resource\_info data is provided through a dri\_cpu structure. Otherwise a dri\_mem structure is used.

On a Micro-Partitioning<sup>™</sup> partition, if the request is CPU-capacity based, the *resource\_info* data is provided through a dri\_cpu\_capacity structure, which has the following format. The kernel extensions are not notified of changes in variable capacity weight in an uncapped Micro-Partitioning<sup>™</sup> environment.

```
*/
struct dri cpu capacity {
uint64 t ent capacity; /* partition current entitled capacity*/
int delta ent cap; /* delta capacity added/removed*/
int status; /* capacity update constrained or not */
* dri_cpu_capacity.status flags.
#define CAP UPDATE SUCCESS 0x0
#define CAP_UPDATE_CONSTRAINED 0x1
```

**Note:** The capacity update is constrained by the Hypervisor.

If the request is memory capacity based, the resource\_info data is provided through a dri\_mem\_capacity structure, which has the following format:

```
struct dri mem capacity {
 size64_t mem_capacity; /* partition current entitled capacity*/
 ssize64_t delta_mem_capacity;
 uint flags;
 int status; /* capacity update constrained or not */
 uchar reserved[7];
};
    * dri_mem_capacity.status flags.
 #define CAP_UPDATE_SUCCESS 0x0

### **Return Values**

Upon successful completion, the reconfig\_register, reconfig\_register\_ext and reconfig\_unregister kernel services return zero. If unsuccessful, the appropriate errno value is returned.

### **Execution Environment**

The reconfig\_register, reconfig\_register\_ext, reconfig\_unregister, and handler interfaces are invoked in the process environment only.

The **reconfig** complete kernel service may be invoked in the process or interrupt environment.

### **Related Information**

Making Kernel Extensions DLPAR-Aware in AIX® Version 7.1 General Programming Concepts: Writing and Debugging Programs.

### refmon Kernel Service

### **Purpose**

Performs various access checks such as privileges, authorizations, discretionary access control checks and so on.

```
#include <refmon.h>
int refmon (crp, action, flags, nargs, args[])
cred t *crp;
rfm_action_t action;
uint t flags;
int nargs;
void *args[];
```

### **Parameters**

Specifies the caller's (subject) credentials; If NULL, then current process credentials are referenced. crp

action Specifies the type of access check that needs to be carried out.

flags Enables auditing of this event. You can only set this parameter to the value of REFMON\_AUDIT.

Specifies the number of arguments in the args parameter. nargs

args Specifies an array of void pointers used as input to the refmon kernel service based on the action

parameter.

# **Description**

The **refmon** kernel service provides an interface to perform various access checks. You can call the refmon kernel service to determine access to system resources. Most of the actions that are passed to the refmon kernel service check for specific privileges. Many of the system calls and kernel services call the **refmon** kernel service to check whether you are authorized or privileged to use such functions. The action parameter determines which type of checks needs to be performed. The sys/refmon.h header file contains a complete list of these actions and their corresponding description.

### **Execution Environment**

The **refmon** kernel service can be called from the process environment only.

### **Return Values**

**EINVAL** The action parameter is not valid or a value that is not allowed is passed in for an action.

**EPERM** The caller does not have permission to perform the intended action.

#### **Related Information**

# register\_HA\_handler Kernel Service

# **Purpose**

Registers a High Availability Event Handler with the Kernel.

# **Syntax**

#include <sys/high avail.h>

int register\_HA\_handler (ha\_handler) ha handler ext t \* ha handler;

#### **Parameter**

ha\_handler

Specifies a pointer to a structure of the type ha\_handler\_ext\_t as defined in /usr/include/sys/ high\_avail.h.

### **Description**

The register\_HA\_handler kernel registers the High Availability Event Handler (HAEH) function to those kernel extensions that need to be made aware of high availability events such as processor deallocation. This function is called by the kernel, at base level, when a high availability event is initiated, due to some hardware fault.

The **ha\_handler\_ext\_t** structure has 3 fields:

Field	Description
_fun	Contains a pointer to the high availability event handler function.
_data	Contains a user defined value which will be passed as an argument by the kernel when calling the function.
_name	Component name

When a high availability event is initiated, the kernel calls fun() at base level (that is, process environment) with 2 parameters:

- The first is the data the user passed in the data field at registration time.
- The second is a pointer to a haeh event t structure defined in /usr/include/sys/high avail.h.

The fields of interest in this structure are:

Field	Description
_magic	Identifies the event type. The only possible value is HA_CPU_FAIL.
dealloc_cpu	The logical number of the CPU being deallocated.

The high availability even handler, in addition to user specific functions, must unbind its threads bound to dealloc\_cpu and stop the timer request blocks (TRB) started by those bound threads when applicable.

The high availability event handler must return one of the following values:

Value	Description
HA_ACCEPTED	The user processing of the event has succeeded.
HA_REFUSED	The user processing of the event was not successful.

Any return value different from HA ACCEPTED causes the kernel to abort the processing of the event. In the case of a processor failure, the processor deallocation is aborted. In this case, a CPU DEALLOC ABORTED error log entry is created, and the value passed in the \_name field appears in the detailed data area of the error log entry.

An extension may register the same HAEH N times (N > 1). Although it is considered as an incorrect behaviour, no error is reported. The given HAEH is invoked N times for each HA event. This handler has to be unregistered as many times as it was registered.

Since the kernel calls the HAEH in turn, it is possible for a HAEH to be called multiple times for the same event. The kernel extensions should be ready to deal with this possibility. For example, two kernel extensions K1 and K2 have registered HA Handlers. A CPU deallocation is initiated. The HAEH for K1 gets invoked, does its job and returns HA ACCEPTED. K2 gets invoked next and for some reason returns HA REFUSED. The deallocation is aborted, and an error log entry reports **K2** as the reason for failure. Later, the system administer unloads **K2** and restarts the deallocation by manually running ha star. The result is that the HAEH for **K1** gets invoked again with the same parameters.

### **Execution Environment**

The register\_HA\_handler kernel service can be called from the process environment only.

### **Return Values**

0

Indicates a successful operation.

A non zero value indicates an error.

#### **Related Information**

The unregister\_HA\_handler kernel service.

The RAS Kernel Services in the AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### rmalloc Kernel Service

### **Purpose**

Allocates an area of memory from the real\_heap heap.

### **Syntax**

#include <sys/types.h> caddr t rmalloc (size, align) int size int align

### **Parameters**

size Specifies the number of bytes to allocate. align Specifies alignment characteristics.

# **Description**

The **rmalloc** kernel service allocates an area of memory from the contiguous real memory heap. This area is the number of bytes in length specified by the size parameter and is aligned on the byte boundary specified by the align parameter. The align parameter is actually the log base 2 of the desired address boundary. For example, an align value of 4 requests that the allocated area be aligned on a 16-byte boundary.

The contiguous real memory heap, real\_heap, is a heap of contiguous real memory pages located in the low 16MB of real memory. This heap is virtually mapped into the kernel extension's address space. By nature, this heap is implicitly pinned, so no explicit pinning of allocated regions is necessary.

The real\_heap heap is useful for devices that require DMA transfers greater than 4K but do not provide a scatter/gather capability. Such a device must be given contiguous bus addresses by its device driver. The device driver should pass the DMA CONTIGUOUS flag on its d map init call in order to obtain contiguous mappings. On certain platforms it is possible that a d\_map\_init call using the **DMA CONTIGUOUS** flag could fail. In this case, the device driver can make use of the **real heap** heap (using rmalloc) to obtain contiguous bus addresses for its device driver. Because the real\_heap heap is a limited resource, device drivers should always attempt to use the DMA\_CONTIGUOUS flag first.

On unsupported platforms, the **rmalloc** service returns NULL if the requested memory cannot be allocated.

The rmfree kernel service should be called to free allocation from a previous rmalloc call. The rmalloc kernel service can be called from the process environment only.

### **Return Values**

Upon successful completion, the rmalloc kernel service returns the address of the allocated area. A NULL pointer is returned if the requested memory cannot be allocated.

### **Related Information**

The rmfree kernel service.

### rmfree Kernel Service

### **Purpose**

Frees memory allocated by the rmalloc kernel service.

# **Syntax**

#include <sys/types.h>

int rmfree ( pointer, size) caddr t pointer int size

### **Parameters**

Specifies the address of the area in memory to free. pointer size Specifies the size of the area in memory to free.

# **Description**

The rmfree kernel service frees the area of memory pointed to by the pointer parameter in the contiguous real memory heap. This area of memory must be allocated with the rmalloc kernel service, and the pointer must be the pointer returned from the corresponding **rmalloc** kernel service call. Also, the size must be the same size that was used on the corresponding rmalloc call.

Any memory allocated in a prior rmalloc call must be explicitly freed with an rmfree call. This service can be called from the process environment only.

#### **Return Values**

- Indicates successful completion.
- Indicates one of the following:
  - · The area was not allocated by the **rmalloc** kernel service.
  - · The heap was not initialized for memory allocation.

#### **Related Information**

The rmalloc kernel service.

# rmmap\_create Kernel Service

# **Purpose**

Defines an Effective Address [EA] to Real Address [RA] translation region.

### **Syntax**

```
#include <sys/ioacc.h>
#include <sys/adspace.h>
int rmmap create ( eaddrp, iomp, flags)
void **eaddrp;
struct io map *iomp:
int flags;
```

### **Parameters**

flags

eaddr Desired process effective address of the mapping region.

The bus memory to which the effective address described by the eaddr parameter should correspond. For amoi real memory, the bus id should be set to REALMEM\_BID and the bus address should be set to the real memory address. The size field must be at least PAGESIZE, no larger than SEGSIZE, and a multiple of

PAGESIZE. The key should be set to IO MEM MAP. The flags field is not used.

The flags select page and segment attributes of the translation. Not all page attribute flags are compatible. See below for the valid combinations of page attribute flags.

#### RMMAP PAGE W

PowerPC® "Write Through" page attribute. Write-through mode is not supported, and if this flag is set, EINVAL is reported.

#### RMMAP\_PAGE\_I

PowerPC® "Cache Inhibited" page attribute. This flag is valid for I/O mappings, but is not allowed for real memory mappings.

#### RMMAP\_PAGE\_M

PowerPC® "Memory Coherency Required" page attribute. This flag is optional for I/O mappings; however, it is required for memory mappings. The default operating mode for real memory pages has this bit set.

#### RMMAP PAGE G

PowerPC® "Guarded" page attribute. This flag is optional for I/O mappings, and must be 0 for real memory mappings. Note that although optional for I/O, it is strongly recommended that this be set for I/O mappings. When set, the processor will not make unnecessary (speculative) references to the page. This includes out of order read/write operations and branch fetching. When clear, normal PowerPC® speculative execution rules apply. This bit does not exist on the PowerPC® 601 RISC Microprocessor (running AIX® 5.1 or earlier) and is ignored.

### RMMAP\_RDONLY

When set, the page protection bits used in the HTAB will not allow write operations regardless of the setting of the key bit in the associated segment register. Exactly one of RMMAP\_RDONLY and RMMAP\_RDWR must be specified.

#### RMMAP RDWR

When set, the page protection bits used in the HTAB will allow read and write operations regardless of the setting of the key bit in the associated segment register. Exactly one of: RMMAP\_RDONLY, and RMMAP\_RDWR must be specified.

#### RMMAP\_PRELOAD

When set, the protection attributes of this region will be entered immediately into the hardware page table. This is very slow initially, but prevents each referenced page in the region from faulting in separately. This is only advisory. This flag is not maintained as an attribute of the map region, it is used only during the current call.

#### RMMAP\_INHERIT

When set, this specifies that the translation region created by this rmmap\_create invocation should be inherited on a fork operation, to the child process. This inheritance is achieved with copy-semantics. That is to say that the child will have its own private mapping to the same I/O or real memory address range as the parent.

### **Description**

The translation regions created with **rmmap** create kernel service are maintained in I/O mapping segments. Any single such segment may translate up to 256 Megabytes of real memory or memory mapped I/O in a single region. The only granularity for which the rmmap\_remove service may be invoked is a single mapping created by a single call to the **rmmap create**.

There are constraints on the size of the mapping and the flags parameter, described later, which will cause the call to fail regardless of whether adequate effective address space exists.

If **rmmap** create kernel service is called with the effective address of zero (0), the function attempts to find free space in the process address space. If successful, an I/O mapping segment is created and the effective address (which is passed by reference) is changed to the effective address which is mapped to the first page of the iomp memory.

If rmmap create kernel service is called with a non-zero effective address, it is taken as the desired effective address which should translate to the passed iomp memory. This function verifies that the requested range is free. If not, it fails and returns EINVAL. If the mapping at the effective address is not contained in a single segment, the function fails and returns ENOSPC. Otherwise, the region is allocated and the effective address is not modified. The effective address is mapped to the first page of the iomp memory. References outside of the mapped regions but within the same segment are invalid.

The effective address (if provided) and the bus address must be a multiple of PAGESIZE or EINVAL is returned.

I/O mapping segments are not inherited by child processes after a **fork** subroutine.

I/O mapping segments are not inherited by child processes after a **fork** subroutine, except when RMMAP INHERIT is specified. These segments are deleted by exec, exit, or rmmap\_remove of the last range in a segment.

Only certain combinations of flags are permitted, depending on the type of memory being mapped. For real memory mappings, RMMAP\_PAGE\_M is required while RMMAP\_PAGE\_W, RMMAP\_PAGE\_I, and RMMAP PAGE G are not allowed. For I/O mappings, it is valid to specify only RMMAP PAGE M, with no other page attribute flags. It is also valid to specify RMMAP PAGE I and optionally, either or both of RMMAP\_PAGE\_M, and RMMAP\_PAGE\_G. RMMAP\_PAGE\_W is never allowed.

The real address range described by the *iomp* parameter must be unique within this I/O mapping segment.

### **Execution Environment**

The **rmmap\_create** kernel service can only be called from the process environment.

#### Return Values

On successful completion, rmmap create kernel service returns zero and modifies the effective address to the value at which the newly created mapping region was attached to the process address space. Otherwise, it returns one of:

EINVAL Some type of parameter error occurred. These include, but are not limited to, size errors and mutually exclusive flag selections.

**ENOMEM** The operating system could not allocate the necessary data structures to represent the mapping.

Effective address space exhausted in the region indicated by eaddr. **ENOSPC** 

**EPERM** This hardware platform does not implement this service.

### Implementation Specifics

This service only functions on PowerPC® microprocessors.

#### **Related Information**

The **rmmap remove** kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### rmmap getwimg Kernel Service

### **Purpose**

Returns wimg information about a particular effective address range within an effective address to real address translation region.

# **Syntax**

#include <sys/adspace.h> int rmmap\_getwimg(eaddr, npages, results) unsigned long long eaddr; unsigned int npages; char\* results;

#### **Parameters**

eaddr

The process effective address of the start of the desired mapping region. This address should point somewhere inside the first page of the range. This address is interpreted as a 64-bit quantity if the current user address space is 64-bits, and is interpreted as a 32-bit (not remapped) quantity if the current user address space is 32-bits.

npages results

The number of pages whose wimg information is returned, starting from the page indicated by eaddr. This is an array of bytes, where the wimg information is returned. The address of this is passed in by the caller, and rmmap getwimg stores the wimg information for each page in the range in each successive byte in this array. The size of this array is indicated by npages as specified by the caller. The caller is responsible for ensuring that the storage allocated for this array is large enough to hold npage bytes.

# **Description**

The wimg information corresponding to the input effective address range is returned.

This routine only works for regions previously mapped with an I/O mapping segment as created by rmmap create.

npages should not be such that the range crosses a segment boundary. If it does, EINVAL is returned.

The wimg information is returned in the **results** array. Each element of the **results** array is a character. Each character may be added with the following fields to examine wimg information: RMMAP PAGE W. RMMAP\_PAGE\_I, RMMAP\_PAGE\_M or RMMAP\_PAGE\_G. The array is valid if the return value is 0.

#### **Execution Environment**

The **rmmap\_getwimg** kernel service is called from the process environment only.

### **Return Values**

**0** Successful completion. Indicates that the *results* array is valid and should be examined.

**EINVAL** 

An error occurred. Most likely the region was not mapped via **rmmap\_create** previously..

**EINVAL** Input range crosses a certain boundary.

**EINVAL** The hardware platform does not implement this service.

### **Implementation Specifics**

This service only functions on PowerPC® microprocessors.

### **Related Information**

The rmmap\_create kernel service, the rmmap\_remove kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### rmmap\_remove Kernel Service

### **Purpose**

Destroys an effective address to real address translation region.

# **Syntax**

#include <sys/adspace.h>
int rmmap\_remove (eaddrp);
void \*\*eaddrp;

### **Parameters**

eaddrp Pointer to the process effective address of the desired mapping region.

# **Description**

Destroys an effective address to real address translation region. If **rmmap\_remove** kernel service is called with the effective address within the region of a previously created I/O mapping segment, the region is destroyed. This service must be called from the process level.

### **Execution Environment**

The **rmmap\_remove** kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful operation.

**EINVAL** The provided *eaddr* does not correspond to a valid I/O mapping segment.

**EINVAL** This hardware platform does not implement this service.

# Implementation Specifics

This service only functions on PowerPC® microprocessors.

The rmmap\_create Kernel Service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### rtalloc Kernel Service

### **Purpose**

Allocates a route.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/route.h>
void rtalloc ( ro)
register struct route *ro;
```

### **Parameter**

Specifies the route.

# **Description**

The rtalloc kernel service allocates a route, which consists of a destination address and a reference to a routing entry.

### **Execution Environment**

The **rtalloc** kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The **rtalloc** service has no return values.

# **Example**

To allocate a route, invoke the **rtalloc** kernel service as follows: rtalloc(ro);

### **Related Information**

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# rtalloc\_gr Kernel Service

# **Purpose**

Allocates a route.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/route.h>
void rtalloc_gr ( ro, gidlist)
register struct route *ro;
struct gidstruct *gidlist;
```

### **Parameter**

Specifies the route. Points to the group list. gidlist

# **Description**

The rtalloc\_gr kernel service allocates a route, which consists of a destination address and a reference to a routing entry.

A route can be allocated only if its group id restrictions specify that it can be used by a user with the gidlist that is passed in.

### **Execution Environment**

The rtalloc\_gr kernel service can be called from either the process or interrupt environment.

### Return Values

The rtalloc\_gr service has no return values.

# Example

To allocate a route, invoke the **rtalloc gr** kernel service as follows: rtalloc gr (ro, gidlist);

#### **Related Information**

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

The rtalloc kernel service.

### rtfree Kernel Service

# **Purpose**

Frees the routing table entry.

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/route.h>
int rtfree ( rt)
register struct rtentry *rt;
```

### **Parameter**

rt Specifies the routing table entry.

### **Description**

The rtfree kernel service frees the entry it is passed from the routing table. If the route does not exist, the panic service is called. Otherwise, the rtfree service frees the mbuf structure that contains the route and decrements the routing reference counters.

### **Execution Environment**

The **rtfree** kernel service can be called from either the process or interrupt environment.

### **Return Values**

The rtfree kernel service has no return values.

# **Example**

To free a routing table entry, invoke the **rtfree** kernel service as follows: rtfree(rt);

### Related Information

The panic kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### rtinit Kernel Service

# **Purpose**

Sets up a routing table entry typically for a network interface.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/socket.h>
#include <net/route.h>
int rtinit (ifa, cmd, flags)
struct ifaddr * ifa;
int cmd, flags;
```

#### **Parameters**

ifa Specifies the address of an ifaddr structure containing destination address, interface address, and

netmask.

Specifies a request to add or delete route entry. cmd

flags Identifies routing flags, as defined in the /usr/include/net/route.h file.

# **Description**

The **rtinit** kernel service creates a routing table entry for an interface. It builds an **rtentry** structure using the values in the *ifa* and *flags* parameters.

The **rtinit** service then calls the **rtrequest** kernel service and passes the *cmd* parameter and the **rtentry** structure to process the request. The *cmd* parameter contains either the value **RTM\_ADD** (a request to add the route entry) or the value **RTM\_DELETE** (delete the route entry). Valid routing flags to set are defined in the **/usr/include/route.h** file.

### **Execution Environment**

The rtinit kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The **rtinit** kernel service returns values from the **rtrequest** kernel service.

### **Example**

To set up a routing table entry, invoke the rtinit kernel service as follows:

```
rtinit(ifa, RMT ADD, flags ( RTF DYNAMIC);
```

### **Related Information**

The rtrequest kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### rtredirect Kernel Service

### **Purpose**

Forces a routing table entry with the specified destination to go through a given gateway.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
#include <net/route.h>

rtredirect ( dst, gateway, netmask, flags, src, rtp)
struct sockaddr *dst, *gateway, *netmask, *src;
int flags;
struct rtentry **rtp;
```

#### **Parameters**

dst Specifies the destination address. gateway Specifies the gateway address.

netmask Specifies the network mask for the route.

flags Indicates routing flags as defined in the /usr/include/net/route.h file.

src Identifies the source of the redirect request.

rtp Indicates the address of a pointer to a **rtentry** structure. Used to return a constructed route.

# **Description**

The **rtredirect** kernel service forces a routing table entry for a specified destination to go through the given gateway. Typically, the rtredirect service is called as a result of a routing redirect message from the network layer. The dst, gateway, and flags parameters are passed to the rtrequest kernel service to process the request.

### **Execution Environment**

The rtredirect kernel service can be called from either the process or interrupt environment.

### **Return Values**

Indicates a successful operation.

If a bad redirect request is received, the routing statistics counter for bad redirects is incremented.

### **Example**

To force a routing table entry with the specified destination to go through the given gateway, invoke the rtredirect kernel service:

```
rtredirect(dst, gateway, netmask, flags, src, rtp);
```

### **Related Information**

The rtinit kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# rtrequest Kernel Service

# **Purpose**

Carries out a request to change the routing table.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
#include <net/if.h>
#include <net/af.h>
#include <net/route.h>
int rtrequest (req, dst, gateway, netmask, flags, ret nrt)
int req;
struct sockaddr *dst, *gateway, *netmask;
int flags;
struct rtentry **ret nrt;
```

#### **Parameters**

Specifies a request to add or delete a route. req dst Specifies the destination part of the route. Specifies the gateway part of the route. gateway

netmask Specifies the network mask to apply to the route.

Identifies routing flags, as defined in the /usr/include/net/route.h file. flags

### **Description**

The **rtrequest** kernel service carries out a request to change the routing table. Interfaces call the **rtrequest** service at boot time to make their local routes known for routing table local operations. Interfaces also call the **rtrequest** service as the result of routing redirects. The request is either to add (if the *req* parameter has a value of **RMT\_ADD**) or delete (the *req* parameter is a value of **RMT\_DELETE**) the route.

#### **Execution Environment**

The **rtrequest** kernel service can be called from either the process or interrupt environment.

### **Return Values**

Indicates a successful operation.

**ESRCH** Indicates that the route was not there to delete.

**EEXIST** Indicates that the entry the **rtrequest** service tried to add already exists. **ENETUNREACH** Indicates that the **rtrequest** service cannot find the interface for the route.

**ENOBUFS** Indicates that the **rtrequest** service cannot get an **mbuf** structure to add an entry.

### **Example**

To carry out a request to change the routing table, invoke the **rtrequest** kernel service as follows: rtrequest(RTM ADD, dst, gateway, netmask, flags, &rtp);

### **Related Information**

The rtinit kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# rtrequest\_gr Kernel Service

# **Purpose**

Carries out a request to change the routing table.

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
#include <net/if.h>
#include <net/af.h>
#include <net/route.h>

int rtrequest_gr ( req, dst, gateway, netmask, flags, ret_nrt, rt_parm)
int req;
struct sockaddr *dst, *gateway, *netmask;
int flags;
struct rtentry **ret_nrt;
struct rtreq parm *rt parm;
```

### **Parameters**

Specifies a request to add or delete a route. rea Specifies the destination part of the route. dst Specifies the gateway part of the route. gateway

Specifies the network mask to apply to the route. netmask

flags Identifies routing flags, as defined in the /usr/include/net/route.h file.

ret\_nrt Specifies to return the resultant route.

Points to the rtreq\_parm structure. The /usr/include/net/radix.h file contains the rtreq\_parm rt\_parm

structure. Through this structure, the route attributes like group list, policy, weight, WPAR ID, interface

can be specified.

# **Description**

The **rtrequest** gr kernel service carries out a request to change the routing table. Interfaces call the rtrequest\_gr service at boot time to make their local routes known for routing table ioctl operations. Interfaces also call the rtrequest gr service as the result of routing redirects. The request is either to add (if the req parameter has a value of RMT\_ADD) or delete (the req parameter is a value of RMT\_DELETE) the route.

### **Execution Environment**

The **rtrequest** gr kernel service can be called from either the process or interrupt environment.

### **Return Values**

Indicates a successful operation.

**ESRCH** Indicates that the route was not there to delete.

**EEXIST** Indicates that the entry the rtrequest\_gr service tried to add already exists. **ENETUNREACH** Indicates that the **rtrequest\_gr** service cannot find the interface for the route.

**ENOBUFS** Indicates that the rtrequest gr service cannot get an mbuf structure to add an entry.

# **Example**

To carry out a request to change the routing table, invoke the **rtrequest\_gr** kernel service as follows: rtrequest gr(RTM ADD, dst, gateway, netmask, flags, &rtp, &rtreq);

### **Related Information**

The rtinit kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

The **rtrequest** kernel service.

# rusage incr Kernel Service

# **Purpose**

Increments a field of the rusage structure.

# **Syntax**

#include <sys/encap.h>

```
void rusage_incr ( field, amount)
int field;
int amount;
```

#### **Parameters**

field Specifies the field to increment. It must have one of the following values:

#### **RUSAGE INBLOCK**

Denotes the ru inblock field. This field specifies the number of times the file system performed input.

#### RUSAGE\_OUTBLOCK

Denotes the ru outblock field. This field specifies the number of times the file system performed

#### RUSAGE\_MSGRCV

Denotes the ru msgrcv field. This field specifies the number of IPC messages received.

#### **RUSAGE MSGSENT**

Denotes the ru msgsnd field. This field specifies the number of IPC messages sent.

Specifies the amount to increment to the field. amount

# **Description**

The rusage\_incr kernel service increments the field specified by the field parameter of the calling process' rusage structure by the amount amount.

### **Execution Environment**

The **rusage** incr kernel service can be called from the process environment only.

#### **Return Values**

The **rusage** incr kernel service has no return values.

### **Related Information**

The **getrusage** subroutine.

### schednetisr Kernel Service

# **Purpose**

Schedules or invokes a network software interrupt service routine.

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/netisr.h>
int schednetisr ( anisr)
int anisr;
```

### **Parameter**

anisr

Specifies the software interrupt number to issue. Refer to **netisr.h** for the range of values of *anisr* that are already in use. Also, other kernel extensions that are not AIX® and that use network ISRs currently running on the system can make use of additional values not mentioned in **netisr.h**.

### **Description**

The **schednetisr** kernel service schedules or calls a network interrupt service routine. The **add\_netisr** kernel service establishes interrupt service routines. If the service was added with a service level of **NET\_OFF\_LEVEL**, the **schednetisr** kernel service directly calls the interrupt service routine. If the service level was **NET\_KPROC**, a network kernel dispatcher is notified to call the interrupt service routine.

### **Execution Environment**

The schednetisr kernel service can be called from either the process or interrupt environment.

### **Return Values**

**EFAULT** Indicates that a network interrupt service routine does not exist for the specified interrupt number.

**EINVAL** Indicates that the *anisr* parameter is out of range.

### **Related Information**

The add\_netisr kernel service, del\_netisr kernel service.

Network Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# selnotify Kernel Service

# **Purpose**

Wakes up processes waiting in a **poll** or **select** subroutine or in the **fp poll** kernel service.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>

void selnotify ( id,  subid,  rtnevents)
int id;
int subid;
ushort rtnevents;
```

### **Parameters**

id Indicates a primary resource identification value. This value along with the subidentifier (specified

by the *subid* parameter) is used by the kernel to notify the appropriate processes of the occurrence of the indicated events. If the resource on which the event has occurred is a device driver, this parameter must be the device major/minor number (that is, a **dev\_t** structure that has been cast to an **int**). The kernel has reserved values for the *id* parameter that do not conflict with possible

device major or minor numbers for sockets, message queues, and named pipes.

subid Helps identify the resource on which the event has occurred for the kernel. For a multiplexed

device driver, this is the number of the channel on which the requested events occurred. If the

device driver is nonmultiplexed, the *subid* parameter must be set to 0.

rtnevents

Consists of a set of bits indicating the requested events that have occurred on the specified device or channel. These flags have the same definition as the event flags that were provided by the events parameter on the unsatisfied call to the object's select routine.

# **Description**

The **selnotify** kernel service should be used by device drivers that support select or poll operations. It is also used by the kernel to support select or poll requests to sockets, named pipes, and message queues.

The **selnotify** kernel service wakes up processes waiting on a **select** or **poll** subroutine. The processes to be awakened are those specifying the given device and one or more of the events that have occurred on the specified device. The select and poll subroutines allow a process to request information about one or more events on a particular device. If none of the requested events have yet happened, the process is put to sleep and re-awakened later when the events actually happen.

The **selnotify** service should be called whenever a previous call to the device driver's **ddselect** entry point returns and both of the following conditions apply:

- · The status of all requested events is false.
- Asynchronous notification of the events is requested.

The **selnotify** service can be called for other than these conditions but performs no operation.

### **Sequence of Events for Asynchronous Notification**

The device driver must store information about the events requested while in the driver's ddselect routine under the following conditions:

- · None of the requested events are true (at the time of the call).
- The POLLSYNC flag is not set in the events parameter.

The **POLLSYNC** flag, when not set, indicates that asynchronous notification is desired. In this case, the selnotify service should be called when one or more of the requested events later becomes true for that device and channel.

When the device driver finds that it can satisfy a select request, (perhaps due to new input data) and an unsatisfied request for that event is still pending, the **selnotify** service is called with the following items:

- Device major and minor number specified by the id parameter
- · Channel number specified by the subid parameter
- Occurred events specified by the rtnevents parameter

These parameters describe the device instance and requested events that have occurred on that device. The notifying device driver then resets its requested-events flags for the events that have occurred for that device and channel. The reset flags thus indicate that those events are no longer requested.

If the rtnevents parameter indicated by the call to the selnotify service is no longer being waited on, no processes are awakened.

### **Execution Environment**

The selnotify kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The **selnotify** service has no return values.

### **Implementation Specifics**

The selnotify kernel service is part of Base Operating System (BOS) Runtime.

### **Related Information**

The **ddselect** device driver entry point.

The **fp\_poll** kernel service, **fp\_select** kernel service, **selreg** kernel service.

The **poll** subroutine, **select** subroutine.

Kernel Extension and Device Driver Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# selreg Kernel Service

### **Purpose**

Registers an asynchronous poll or select request with the kernel.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/poll.h>
int selreg ( corl, dev_id, unique_id, reqevents, notify)
int corl;
int dev_id;
int unique id;
ushort reqevents;
void (*notify) ();
```

### **Parameters**

corl	The correlator for the poll or select request. The <i>corl</i> parameter is used by the <b>poll</b> and <b>select</b> subroutines to correlate the returned events in a specific select control block with a process' file descriptor or message queue.
dev_id	Primary resource identification value. Along with the <i>unique_id</i> parameter, the <i>dev_id</i> parameter is used to record in the select control block the resource on which the requested poll or select events are expected to occur.
unique_id	Unique resource identification value. Along with the <code>dev_id</code> parameter, the <code>unique_id</code> parameter denotes the resource on which the requested events are expected to occur. For a multiplexed device driver, this parameter specifies the number of the channel on which the requested events are expected to occur. For a nonmultiplexed device driver, this parameter must be set to 0.
reqevents	Requested events parameter. The <i>reqevents</i> parameter consists of a set of bit flags denoting the events for which notification is being requested. These flags have the same definitions as the event flags provided by the <i>events</i> parameter on the unsatisfied call to the object's <b>select</b> subroutine (see the <b>sys/poll.h</b> file for the definitions).
	Note: The POLLSYNC bit flag should not be set in this parameter.

Notification routine entry point. This parameter points to a notification routine used for nested poll

notify

and select calls.

## **Description**

The **selreg** kernel service is used by **select** file operations in the top half of the kernel to register an unsatisfied asynchronous poll or select event request with the kernel. This registration enables later calls to the selnotify kernel service from resources in the bottom half of the kernel to correctly identify processes awaiting events on those resources.

The event requests may originate from calls to the **poll** or **select** subroutine, from processes, or from calls to the fp\_poll or fp\_select kernel service. A select file operation calls the selreg kernel service under the following circumstances:

- The poll or select request is asynchronous (the POLLSYNC flag is not set for the requested event's bit flags).
- The poll or select request determines (by calling the underlying resource's ddselect entry point) that the requested events have not yet occurred.

A registered event request takes the form of a select control block. The select control block is a structure containing the following:

- · Requested event bit flags
- · Returned event bit flags
- Primary resource identifier
- · Unique resource identifier
- · Pointer to a proc table entry
- File descriptor correlator
- Pointer to a notification routine that is non-null only for nested calls to the poll and select subroutines

The selreg kernel service allocates and initializes a select control block each time it is called.

When an event occurs on a resource that supports the select file operation, the resource calls the selnotify kernel service. The selnotify kernel service locates all select control blocks whose primary and unique identifiers match those of the resource, and whose requested event flags match the occurred events on the resource. Then, for each of the matching control blocks, the selnotify kernel service takes one of two courses of action, depending upon whether the control block's notification routine pointer is non-null (nested) or null (non-nested):

- In nested calls to the **select** or **poll** subroutines, the notification routine is called with the primary and unique resource identifiers, the returned event bit flags, and the process identifiers.
- In non-nested calls to the **select** or **poll** subroutine (the usual case), the SSEL bit of the process identified in the block is cleared, the returned event bit flags in the block are updated, and the process is awakened. A process awakened in this manner completes the poll or select call in which it was sleeping. The **poll** or **select** subroutine then collects the returned event bit flags in its processes' select control blocks for return to the user mode process, deallocates the control blocks, and returns tallys of the numbers of requested events that occurred to the user process.

### **Execution Environment**

The **selreg** kernel service can be called from the process environment only.

#### **Returns Values**

Indicates successful completion.

**EAGAIN** Indicates the selreg kernel service was unable to allocate a select control block.

### **Related Information**

The **ddselect** device driver entry point.

The fp\_poll kernel service, fp\_select kernel service, selnotify kernel service.

The **poll** subroutine, **select** subroutine.

Select and Poll Support and Kernel Extension and Device Driver Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## set pag or set pag64 Kernel Service

## **Purpose**

Sets a Process Authentication Group (PAG) value for the current process.

## **Syntax**

```
#include <sys/cred.h>
int set_pag ( type, pag )
int type;
int pag;
int set_pag64 ( type, pag )
int type;
uint64_t *pag;
```

### **Parameters**

type PAG type to change pag PAG value

# **Description**

The set\_pag or set\_pag64 kernel service copies the requested PAG for the current process. The caller must synchronize the set\_pag and set\_pag64 kernel services with validate\_pag because set\_pag and set\_pag64 do not lock process creation across the system. The value of type must be a defined PAG ID. The PAG ID for the Distributed Computing Environment (DCE) is 0.

### **Execution Environment**

The **set\_pag** and **set\_pag64** kernel services can be called from the process environment only.

#### **Return Values**

A value of 0 is returned upon successful completion. Upon failure, a -1 is returned and errno is set to a value that explains the error.

### **Error Codes**

The set\_pag and set\_pag64 kernel services fails if one or both of the following conditions are true:

**EINVAL** Invalid PAG specification

### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### setioctlry Subroutine

## **Purpose**

Sets a value to be returned by an ioctl routine.

## **Syntax**

```
void setioctlrv (ioctlrv)
int ioctlrv;
```

### **Parameters**

ioctlrv

Specifies an integer value to be returned by a successful completion of the ioctl subroutine.

## **Description**

The **setioctlrv** subroutine sets the value of the u\_ioctlrv field in the **uthread** structure of the running thread. The value in the u\_ioctlrv field is returned by theioctl or fp\_ioctl subroutine on a successful completion. If the ioctl subroutine fails, an errno value is returned instead.

### **Return Values**

The **setioctlrv** subroutine returns no return values.

### **Error Codes**

The setioctlrv subroutine returns no error codes.

# setjmpx Kernel Service

# **Purpose**

Allows saving the current execution state or context.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int setjmpx ( jump buffer)
label_t *jump buffer;
```

### **Parameter**

jump\_buffer

Specifies the address of the caller-supplied jump buffer that was specified on the call to the setjmpx service.

## **Description**

The **setimpx** kernel service saves the current execution state, or context, so that a subsequent **longimpx** call can cause an immediate return from the setimpx service. The setimpx service saves the context with the necessary state information including:

- · The current interrupt priority.
- · Whether the process currently owns the kernel mode lock.

Other state variables include the nonvolatile general purpose registers, the current program's table of contents and stack pointers, and the return address.

Calls to the setimpx service can be nested. Each call to the setimpx service causes the context at this point to be pushed to the top of the stack of saved contexts.

### **Execution Environment**

The **setimpx** kernel service can be called from either the process or interrupt environment.

### **Return Values**

Nonzero value Indicates that a longjmpx call caused the setjmpx service to return.

Indicates any other circumstances.

### **Related Information**

The clrimpx kernel service, longimpx kernel service.

Handling Signals While in a System Call, Exception Processing, Implementing Kernel Exception Handlers, Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# setpinit Kernel Service

## **Purpose**

Sets the parent of the current kernel process to the initialization process.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/device.h> int setpinit()

# **Description**

The **setpinit** kernel service can be called by a kernel process to set its parent process to the **init** process. This is done to redirect the death of child signal for the termination of the kernel process. As a result, the init process is allowed to perform its default zombie process cleanup.

The setpinit service is used by a kernel process that can terminate, but does not want the user-mode process under which it was created to receive a death of child process notification.

### **Execution Environment**

The **setpinit** kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful operation.

EINVAL Indicates that the current process is not a kernel process.

### **Related Information**

Using Kernel Processes and Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### setuerror Kernel Service

## Purpose

Allows kernel extensions to set the ut error field for the current thread.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int setuerror ( errno)
int errno;
```

### **Parameter**

Contains a value found in the /usr/include/sys/errno.h file that is to be copied to the current thread ut error field.

# **Description**

The **setuerror** kernel service allows a kernel extension in a process environment to set the **ut error** field in current thread's uthread structure. Kernel extensions providing system calls available to user-mode applications typically use this service. For system calls, the value of the ut\_error field in the per thread uthread structure is copied to the errno global variable by the system call handler before returning to the caller.

### **Execution Environment**

The **setuerror** kernel service can be called from the process environment only.

#### Return Codes

The **setuerror** kernel service returns the *errno* parameter.

### **Related Information**

The getuerror kernel service.

Kernel Extension and Device Driver Management Kernel Services and Understanding System Call Execution in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# shutdown\_notify\_reg Kernel Service

# **Purpose**

Allows kernel extensions to register a shutdown notification.

## **Syntax**

```
#include <sys/reboot.h>
int shutdown notify reg(sn)
shutdown notify t *sn;
typedef struct _shutdown_notify {
struct _shutdown_notify *next; /* Next in the link-list */
int version; /* Version of structure */
                /* Bit map of the operation being performed */
int status; /* The current status of this notify */
uchar cb retry; /* Internal use */
uchar scope; /* Partition or system wide */
uchar reason; /* User initiated or EPOW */
uchar padding; /* padding */
lona
        (*func)(); /* Function kernel calls to notify ext. */
        *uaddr; /* Address to help extension identify the object this structure refers to */
void
} shutdown notify t;
/* Valid values for shutdown_notify_t->oper */
#define SHUTDOWN NOTIFY PREPARE 0x1 /* Shutdown has started */
#define SHUTDOWN NOTIFY REBOOT 0x2 /* Final notify that shutdown will be a reboot */
#define SHUTDOWN_NOTIFY_HALT 0x4 /* Final notify that shutdown will be a halt */
#define SHUTDOWN NOTIFY QUERY 0x8 /* Check to see if finished shutdown */
/* Valid values for shutdown_notify_t->status and for SHUTDOWN_NOTIFY_QUERY return code */
#define SHUTDOWN STATUS PREPARE 0x1 /* Preparing for shutdown */
#define SHUTDOWN STATUS COMMENCE 0x2 /* Commencing shutdown */
#define SHUTDOWN_STATUS_FINISH 0x4 /* Finished shutdown */
#define SHUTDOWN NOTIFY VERSION 1 /* Increment by 1
          * every time add more
          * variables to
          * shutdown_notify_t
          */
/* Valid values for shutdown notify t->scope */
#define SHUTDOWN SCOPE PARTITION 1
#define SHUTDOWN SCOPE SYSTEM 2
/* Valid values for shutdown notify t->reason */
#define SHUTDOWN REASON USER 1
#define SHUTDOWN REASON EPOW 2
/* Valid handler return codes during the SHUTDOWN NOTIFY PREPARE phase */
#define SHUTDOWN RC SUCCESS
#define SHUTDOWN_RC_DELAY
         SHUTDOWN NOTIFY_VERSION 2
#define
```

# Description

The shutdown notify subsystem has been extended to provide additional information during a shutdown operation. During the SHUTDOWN\_NOTIFY\_PREPARE phase, the kernel provides information on the scope and reason for the shutdown action. Additionally, when a handler is called, before its completion, it can now delay the shutdown operation in order to finalize any outstanding jobs. The kernel again then calls out to the handler after some small amount of time. This process continues until all handlers return SHUTDOWN\_RC\_SUCCESS. This functionality is only present for shutdown\_notify\_t version 2 and preceding handlers. For version 1 handlers, the new fields are not present and the return code from the handler is ignored.

#### **Parameters**

Internal use. cb\_retry

func Pointer to the function called to notify registered extension.

next Pointer to next **shutdown\_notify\_t** structure in list.

oper Bit map of operation(s) being performed.

padding Padding.

reason User initiated or EPOW event.

scope Shutdown at the partition or system level.

sn Pointer to a structure that the calling extension fills out when it registers.

status Current status of notify.

uaddr Place for extension to store an address to help it identify the object to

which this structure refers.

version Version of structure. Set to 1.

SHUTDOWN\_NOTIFY\_HALT A halt is occurring.
SHUTDOWN\_NOTIFY\_PREPARE Shutdown has started.

SHUTDOWN\_NOTIFY\_QUERY Check to see if finished shutdown.

SHUTDOWN\_NOTIFY\_REBOOT A reboot is occurring.
SHUTDOWN\_NOTIFY\_VERSION Version number of structure.

SHUTDOWN\_RC\_DELAY Return from registered handler to indicate its processing is not complete

and wants to delay the shutdown operation.

SHUTDOWN\_RC\_SUCCESS Return from registered handler to indicate all processing is complete and

the shutdown operation can proceed.

SHUTDOWN\_REASON\_EPOW EPOW event.

SHUTDOWN\_REASON\_USER
SHUTDOWN\_SCOPE\_PARTITION
SHUTDOWN\_SCOPE\_SYSTEM
User initiated shutdown.
Shutdown at the partition level.
Shutdown at the system level.

SHUTDOWN\_STATUS\_COMMENCE Wrap up shutdown.
SHUTDOWN\_STATUS\_FINISH Shutdown has completed.
SHUTDOWN\_STATUS\_PREPARE Preparing for shutdown.

### **Execution Environment**

Process environment only.

### **Return Values**

O Success.

**EPERM** Attempted to register after prepare notification has started.

**EINVAL** Invalid argument passed.

### **Related Information**

"shutdown\_notify\_unreg Kernel Service."

# shutdown\_notify\_unreg Kernel Service

# **Purpose**

Unregisters an extension from getting notified in the event of a shutdown.

# **Syntax**

#include <sys/reboot.h>

int shutdown\_notify\_unreg(sn)
shutdown\_notify\_t \*sn;

## **Description**

The shutdown\_notify\_unreg kernel service unregisters an extension from getting notified in the event of a shutdown. The extension passes in the shutdown\_notify\_t instance it wants to unregister. This function will fail if it is called after the SHUTDOWN\_NOTIFY\_HALT and SHUTDOWN\_NOTIFY\_REBOOT notification process has started.

### **Parameters**

Pointer to a structure that the calling extension wants to unregister.

### **Execution Environment**

Process environment only.

### **Return Values**

**EPERM** Attempted to unregister after final notification has started.

**EINVAL** Invalid argument passed.

### **Related Information**

"shutdown notify reg Kernel Service" on page 455.

## sig\_chk Kernel Service

## **Purpose**

Provides a kernel process the ability to poll for receipt of signals.

# **Syntax**

```
#include <svs/tvpes.h>
#include <sys/errno.h>
#include <sys/signal.h>
int sig chk ()
```

# Description

Attention: A system crash will occur if the sig\_chk service is not called by a kernel process.

The sig\_chk kernel service can be called by a kernel thread in kernel mode to determine if any unmasked signals have been received. Signals do not preempt threads because serialization of critical data areas would be lost. Instead, threads must poll for signals, either periodically or after a long sleep has been interrupted by a signal.

The **sig\_chk** service checks for any pending signal that has a specified signal catch or default action. If one is found, the service returns the signal number as its return value. It also removes the signal from the pending signal mask. If no signal is found, this service returns a value of 0. The sig\_chk service does not return signals that are blocked or ignored. It is the responsibility of the kernel process to handle the signal appropriately.

For kernel-only threads, the sig\_chk kernel service clears the returned signal from the list of pending signals. For other kernel threads, the signal is not cleared, but left pending. It will be delivered to the kernel thread as soon as it returns to the user mode.

Understanding Kernel Threads in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts provides more information about kernel-only thread signal handling.

### **Execution Environment**

The **sig\_chk** kernel service can be called from the process environment only.

### **Return Values**

Upon completion, the sig\_chk service returns a value of 0 if no pending unmasked signal is found. Otherwise, it returns a nonzero signal value indicating the number of the highest priority signal that is pending. Signal values are defined in the /usr/include/sys/signal.h file.

### **Related Information**

Introduction to Kernel Processes, Process and Exception Management Kernel Services, and Kernel Process Signal and Exception Handling in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# simple\_lock or simple\_lock\_try Kernel Service

## **Purpose**

Locks a simple lock.

## **Syntax**

```
#include <sys/lock_def.h>
void simple lock ( lock addr)
simple_lock_t lock_addr;
boolean t simple lock try ( lock addr)
simple lock t lock addr;
```

#### **Parameter**

lock\_addr

Specifies the address of the lock word to lock.

# Description

The simple\_lock kernel service locks the specified lock; it blocks if the lock is busy. The lock must have been previously initialized with the simple\_lock\_init kernel service. The simple\_lock kernel service has no return values.

The simple lock try kernel service tries to lock the specified lock; it returns immediately without blocking if the lock is busy. If the lock is free, the simple\_lock\_try kernel service locks it. The lock must have been previously initialized with the **simple lock init** kernel service.

Note: When using simple locks to protect thread-interrupt critical sections, it is recommended that you use the disable\_lock kernel service instead of calling the simple\_lock kernel service directly.

### **Execution Environment**

The **simple\_lock** and **simple\_lock\_try** kernel services can be called from the process environment only.

### **Return Values**

The **simple\_lock\_try** kernel service has the following return values:

TRUE Indicates that the simple lock has been successfully acquired. **FALSE** Indicates that the simple lock is busy, and has not been acquired.

### **Related Information**

The disable lock kernel service, lock mine kernel service, simple lock init kernel service, simple unlock kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

# simple lock init Kernel Service

## **Purpose**

Initializes a simple lock.

## **Syntax**

```
#include <sys/lock def.h>
void simple_lock_init ( lock addr)
simple lock t lock addr;
```

### **Parameter**

lock addr

Specifies the address of the lock word.

# **Description**

The simple lock init kernel service initializes a simple lock. This kernel service must be called before the simple lock is used. The simple lock must previously have been allocated with the lock\_alloc kernel service.

### **Execution Environment**

The **simple lock init** kernel service can be called from the process environment only.

The **simple lock init** kernel service may be called either the process or interrupt environments.

### Return Values

The simple lock init kernel service has no return values.

### **Related Information**

The lock\_alloc kernel service, lock\_free kernel service, simple\_lock kernel service, simple\_lock\_try kernel service, simple unlock kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

## simple\_unlock Kernel Service

## **Purpose**

Unlocks a simple lock.

## **Syntax**

```
#include <sys/lock def.h>
void simple_unlock ( lock addr)
simple_lock_t lock addr;
```

### **Parameter**

lock addr

Specifies the address of the lock word to unlock.

## **Description**

The simple\_unlock kernel service unlocks the specified simple lock. The lock must be held by the thread which calls the simple\_unlock kernel service. Once the simple lock is unlocked, the highest priority thread (if any) which is waiting for it is made runnable, and may compete for the lock again. If at least one kernel thread was waiting for the lock, the priority of the calling kernel thread is recomputed.

Note: When using simple locks to protect thread-interrupt critical sections, it is recommended that you use the unlock enable kernel service instead of calling the simple unlock kernel service directly.

### **Execution Environment**

The **simple unlock** kernel service can be called from the process environment only.

### **Return Values**

The **simple unlock** kernel service has no return values.

### **Related Information**

The lock\_mine kernel service, simple\_lock\_init kernel service, simple\_lock kernel service, simple lock try kernel service, unlock enable kernel service.

Understanding Locking and Locking Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts

# sleep Kernel Service

# **Purpose**

Forces the calling kernel thread to wait on a specified channel.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pri.h>
#include <sys/proc.h>
```

```
int sleep ( chan, priflags)
void *chan;
int priflags;
```

### **Parameters**

chan Specifies the channel number. For the sleep service, this parameter identifies the channel to wait for

(sleep on).

Specifies two conditions: priflags

• The priority at which the kernel thread is to run when it is reactivated.

• Flags indicating how a signal is to be handled by the sleep kernel service.

The valid flags and priority values are defined in the /usr/include/sys/pri.h file.

## **Description**

The **sleep** kernel service is provided for compatibility only and should not be invoked by new code. The e sleep thread or et wait kernel service should be used when writing new code.

The **sleep** service puts the calling kernel thread to sleep, causing it to wait for a wakeup to be issued for the channel specified by the *chan* parameter. When the process is woken up again, it runs with the priority specified in the *priflags* parameter. The new priority is effective until the process returns to user mode.

All processes that are waiting on the channel are restarted at once, causing a race condition to occur between the activated threads. Thus, after returning from the sleep service, each thread should check whether it needs to sleep again.

The channel specified by the *chan* parameter is simply an address that by convention identifies some event to wait for. When the kernel or kernel extension detects such an event, the wakeup service is called with the corresponding value in the chan parameter to start up all the threads waiting on that channel. The channel identifier must be unique systemwide. The address of an external kernel variable (which can be defined in a device driver) is generally used for this value.

If the SWAKEONSIG flag is not set in the priflags parameter, signals do not terminate the sleep. If the SWAKEONSIG flag is set and the PCATCH flag is not set, the kernel calls the longimpx kernel service to resume the context saved by the last **setimpx** call if a signal interrupts the sleep. Therefore, any system call (such as those calling device driver ddopen, ddread, and ddwrite routines) or kernel process that does an interruptible sleep without the PCATCH flag set must have set up a context using the setimpx kernel service. This allows the sleep to resume in case a signal is sent to the sleeping process.

Attention: The caller of the sleep service must own the kernel-mode lock specified by the kernel lock parameter. The sleep service does not provide a compatible level of serialization if the kernel lock is not owned by the caller of the sleep service.

### **Execution Environment**

The **sleep** kernel service can be called from the process environment only.

#### Return Values

- 0 Indicates successful completion.
- 1 Indicates that a signal has interrupted a sleep with both the PCATCH and SWAKEONSIG flags set in the priflags parameter.

## subyte Kernel Service

## **Purpose**

Stores a byte of data in user memory.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int subyte ( uaddr, c)
uchar *uaddr;
uchar c;
```

### **Parameters**

Specifies the address of user data. uaddr Specifies the character to store.

## **Description**

The subyte kernel service stores a byte of data at the specified address in user memory. It is provided so that system calls and device heads can safely access user data. The subyte service ensures that the user has the appropriate authority to:

- · Access the data.
- Protect the operating system from paging I/O errors on user data.

The **subyte** service should only be called while executing in kernel mode in the user process.

### **Execution Environment**

The **subyte** kernel service can be called from the process environment only.

### **Return Values**

- Indicates successful completion.
- Indicates a *uaddr* parameter that is not valid for one of the following reasons: -1
  - · The user does not have sufficient authority to access the data.
  - · The address is not valid.
  - · An I/O error occurs when the user data is referenced.

### **Related Information**

The **fubyte** kernel service, **fuword** kernel service, **suword** kernel service.

Accessing User-Mode Data While in Kernel Mode and Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### suser Kernel Service

## **Purpose**

Determines the privilege state of a process.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int suser ( ep)
char *ep;
```

### **Parameter**

ep Points to a character variable where the **EPERM** value is stored on failure.

## **Description**

The **suser** kernel service checks whether a process has any effective privilege (that is, whether the process's uid field equals 0).

### **Execution Environment**

The **suser** kernel service can be called from the process environment only.

### **Return Values**

**0** Indicates failure. The character pointed to by the *ep* parameter is set to the value of

**EPERM**. This indicates that the calling process does not have any effective privilege.

Nonzero value Indicates success (the process has the specified privilege).

### **Related Information**

Security Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### suword Kernel Service

## **Purpose**

Stores a word of data in user memory.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>

int suword ( uaddr, w)
int *uaddr;
int w;
```

### **Parameters**

uaddr Specifies the address of user data.

## **Description**

The **suword** kernel service stores a word of data at the specified address in user memory. It is provided so that system calls and device heads can safely access user data. The suword service ensures that the user had the appropriate authority to:

- Access the data.
- Protect the operating system from paging I/O errors on user data.

The **suword** service should only be called while executing in kernel mode in the user process.

### **Execution Environment**

The **suword** kernel service can be called from the process environment only.

### Return Values

- Indicates successful completion.
- Indicates a *uaddr* parameter that is not valid for one of these reasons:
  - · The user does not have sufficient authority to access the data.
  - · The address is not valid.
  - · An I/O error occurs when the user data is referenced.

### **Related Information**

The **fubyte** kernel service, **fuword** kernel service, **subyte** kernel service.

Memory Kernel Services and Accessing User-Mode Data While in Kernel Mode in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### talloc Kernel Service

# **Purpose**

Allocates a timer request block before starting a timer request.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/timer.h>
struct trb *talloc()
```

# **Description**

The talloc kernel service allocates a timer request block. The user must call it before starting a timer request with the tstart kernel service. If successful, the talloc service returns a pointer to a pinned timer request block.

### **Execution Environment**

The **talloc** kernel service can be called from the process environment only.

### **Return Values**

The talloc service returns a pointer to a timer request block upon successful allocation of a trb structure. Upon failure, a null value is returned.

### **Related Information**

The **tfree** kernel service, **tstart** kernel service, **tstop** kernel service.

Timer and Time-of-Day Kernel Services and Using Fine Granularity Timer Services and Structures in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### tfree Kernel Service

## **Purpose**

Deallocates a timer request block.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/timer.h>
void tfree (t)
struct trb *t;
```

### **Parameter**

Points to the timer request structure to be freed.

# **Description**

The tfree kernel service deallocates a timer request block that was previously allocated with a call to the talloc kernel service. The caller of the tfree service must first cancel any pending timer request associated with the timer request block being freed before attempting to free the request block. Canceling the timer request block can be done using the **tstop** kernel service.

### **Execution Environment**

The tfree kernel service can be called from either the process or interrupt environment.

Note: Do not use the tfree kernel service to free the timer request block that is passed to the timer completion handler.

### **Return Values**

The tfree service has no return values.

### **Related Information**

The talloc kernel service, tstart kernel service, tstop kernel service.

Timer and Time-of-Day Kernel Services and Using Fine Granularity Timer Services and Structures in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### thread create Kernel Service

## **Purpose**

Creates a new kernel thread in the calling process.

## **Syntax**

#include <sys/thread.h> tid\_t thread\_create ()

# **Description**

The thread create kernel service creates a new kernel-only thread in the calling kernel process. The thread's ID is returned; it is unique system wide.

The new thread does not begin running immediately; its state is set to TSIDL. The execution will start after a call to the kthread\_start kernel service. If the process is exited prior to the thread being made runnable, the thread's resources are released immediately. The thread's signal mask is inherited from the calling thread; the set of pending signals is cleared. Signals sent to the thread are marked pending while the thread is in the TSIDL state.

If the calling thread is bound to a specific processor, the new thread will also be bound to the processor.

### **Execution Environment**

The thread create kernel service can be called from the process environment only. This service cannot be called directly from a kernel extension.

### Return Values

Upon successful completion, the new thread's ID is returned. Otherwise, -1 is returned, and the error code can be checked by calling the getuerror kernel service.

### **Error Codes**

**EAGAIN** The total number of kernel threads executing system wide or the maximum number of kernel threads per process would be exceeded.

**ENOMEM** There is not sufficient memory to create the kernel thread.

**ENOTSUP** The **thread\_create** service was called directly from a kernel extension.

### **Related Information**

The kthread start kernel service.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# thread self Kernel Service

# **Purpose**

Returns the caller's kernel thread ID.

## **Syntax**

#include <sys/thread.h> tid t thread self ()

## **Description**

The thread\_self kernel service returns the thread process ID of the calling process.

The thread self service can also be used to check the environment that the routine is being executed in. If the caller is executing in the interrupt environment, the thread self service returns a process ID of -1. If a routine is executing in a process environment, the thread self service obtains the thread process ID.

### **Execution Environment**

The thread self kernel service can be called from either the process or interrupt environment.

### **Return Values**

-1 Indicates that the thread\_self service was called from an interrupt environment.

The thread\_self service returns the thread process ID of the current process if called from a process environment.

### **Related Information**

Process and Exception Management Kernel Services and Understanding Execution Environments in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## thread setsched Kernel Service

# **Purpose**

Sets kernel thread scheduling parameters.

# **Syntax**

```
#include <sys/thread.h>
#include <sys/sched.h>
int thread_setsched ( tid, priority, policy)
tid t tid;
int priority;
int policy;
```

### **Parameters**

Specifies the kernel thread. tid

Specifies the priority. It must be in the range from 0 to PRI\_LOW; 0 is the most favored priority. priority

policy Specifies the scheduling policy. It must have one of the following values:

SCHED\_FIFO

Denotes fixed priority first-in first-out scheduling.

SCHED FIFO2

Allows a thread that sleeps for a relatively short amount of time to be requeued to the head, rather than the tail, of its priority run queue.

SCHED FIFO3

Causes threads to be enqueued to the head of their run queues.

SCHED RR

Denotes fixed priority round-robin scheduling.

SCHED OTHER

Denotes the default scheduling policy.

## **Description**

The **thread\_setsched** subroutine sets the scheduling parameters for a kernel thread. This includes both the priority and the scheduling policy, which are specified in the *priority* and *policy* parameters. The calling and the target thread must be in the same process.

When setting the scheduling policy to **SCHED\_OTHER**, the system chooses the priority; the *priority* parameter is ignored. The only way to influence the priority of a thread using the default scheduling policy is to change the process nice value.

The calling thread must belong to a process with root authority to change the scheduling policy of a thread to either SCHED FIFO, SCHED FIFO2, SCHED FIFO3, or SCHED RR.

### **Execution Environment**

The thread\_setsched kernel service can be called from the process environment only.

#### Return Values

Upon successful completion, 0 is returned. Otherwise, -1 is returned, and the error code can be checked by calling the **getuerror** kernel service.

### **Error Codes**

**EINVAL** The *priority* or *policy* parameters are not valid.

**EPERM** The calling kernel thread does not have sufficient privilege to perform the operation.

**ESRCH** The kernel thread *tid* does not exist.

### **Related Information**

The thread\_create kernel service.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# thread\_set\_smt\_priority or thread\_read\_smt\_priority System Call

# **Purpose**

Sets or reads the current SMT thread priority for a user-thread.

## **Syntax**

```
#include <sys/errno.h>
#include <sys/thread.h>
#include <sys/processor.h>
int thread set smt priority ( Priority )
smt_thread_priority_t Priority;
#include <sys/errno.h>
#include <sys/thread.h>
#include <sys/processor.h>
smt thread priority t thread read smt priority ( )
```

## **Description**

The SMT thread priority associated with a logical CPU, SMT hardware thread, controls the relative priority of the logical CPU in relation to the other logical CPUs residing on the same processor core. The relative priority between the SMT hardware threads on a processor core determines how decode cycles are granted to each SMT hardware thread. The SMT thread priority can be used to cause a particular application thread to be favored over other application threads running on the other SMT hardware threads in the same processor core. This is done by increasing the SMT thread priority of the logical CPU the application is running on, or by lowering the SMT thread priority of the application threads running on the other logical CPUs associated with the same processor core.

The thread set smt priority and thread read smt priority system calls provide a way to register and read back the current desired SMT thread priority on a per process-thread basis.

#### Note:

These interfaces are not supported on some processor architectures.

If the process-thread is dispatched to a logical CPU running in non-SMT mode, the desired SMT thread priority level will have no effect.

Callers of the thread\_set\_smt\_priority system call with normal user-level privileges can set their SMT thread priority level to one of the following levels

- LOW
- MEDIUM
- NORMAL

Callers that have RBAC PV\_PROC\_VARS privilege can set their priority level to one of the following levels

- VERY LOW
- LOW
- MEDIUM LOW
- NORMAL
- MEDIUM HIGH
- HIGH

The default thread priority level is NORMAL.

Note: The only supported means for altering the SMT thread priority level is through the use of the thread set smt priority system call. If an alternate means of setting the SMT priority is used, the kernel will not know the process-thread's current desired SMT priority level, and will overwrite the desired SMT priority level without restoring it.

The thread\_read\_smt\_priority system call returns the current SMT priority level registered by the process thread. If the process thread has not registered a desired SMT priority level, then the default priority level of NORMAL will be returned.

### **Parameters**

**Priority** Used to specify one of the following parameters:

T VERYLOW SMT PRI

• T LOW SMT PRI

• T MEDIUMLOW SMT PRI

• T NORMAL SMT PRI

T MEDIUMHIGH SMT PRI

• T\_HIGH\_SMT\_PRI

### **Execution Environment**

The thread read smt priority and thread set smt priority system calls can be called from the process environment only.

### **Return Values**

On successful completion, the thread\_set\_smt\_priority system call returns 0. Otherwise, -1 is returned and the **errno** global variable is set to indicate the error.

On successful completion, the thread\_read\_smt\_priority system call returns the current desired SMT priority. Otherwise, -1 is returned and the errno global variable is set to indicate the error.

### **Error Codes**

**EPERM** The process attempted to set the SMT thread priority level to a value other than

T\_LOW\_SMT\_PRI, T\_MEDIUMLOW\_SMT\_PRI, or T\_NORMAL\_SMT\_PRI and does not

have the necessary privileges.

EINVAL The desired priority value specified is invalid.

**ENOSYS** SMT thread priority level manipulation is not supported on this system.

# thread terminate Kernel Service

# **Purpose**

Terminates the calling kernel thread.

# **Syntax**

#include <sys/thread.h> void thread terminate ()

# **Description**

The thread terminate kernel service terminates the calling kernel thread and cleans up its structure and its kernel stack. If it is the last thread in the process, the process will exit.

The thread terminate kernel service is automatically called when a thread returns from its entry point routine (defined in the call to the kthread\_start kernel service).

### **Execution Environment**

The thread\_terminate kernel service can be called from the process environment only.

### **Return Values**

The thread terminate kernel service never returns.

### **Related Information**

The kthread start kernel service.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### timeout Kernel Service

**Attention:** This service should not be used in AIX<sup>®</sup> Version 4, because it is not multi-processor safe. The base kernel timer and watchdog services should be used instead. See talloc and w init for more information.

## **Purpose**

Schedules a function to be called after a specified interval.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
void timeout ( func, arg, ticks)
void (*func)();
caddr_t *arg;
int ticks;
```

### **Parameters**

func Indicates the function to be called.

Indicates the parameter to supply to the function specified by the func parameter. arg

Specifies the number of timer ticks that must occur before the function specified by the func parameter is ticks called. Many timer ticks can occur per second. The HZ label found in the /usr/include/sys/m\_param.h file

can be used to determine the number of ticks per second.

# **Description**

The timeout service is not part of the kernel. However, it is a compatibility service provided in the libsys.a library. To use the timeout service, a kernel extension must have been bound with the libsys.a library. The timeout service, like the associated kernel services untimeout and timeoutcf, can be bound and used only in the pinned part of a kernel extension or the bottom half of a device driver because these services use interrupt disable for serialization.

The timeout service schedules the function pointed to by the func parameter to be called with the arg parameter after the number of timer ticks specified by the ticks parameter. Use the timeoutcf routine to allocate enough callout elements for the maximum number of simultaneous active time outs that you expect.

**Note:** The **timeoutcf** routine must be called before calling the **timeout** service.

Calling the timeout service without allocating a sufficient number of callout table entries can result in a kernel panic because of a lack of pinned callout table elements. The value of a timer tick depends on the hardware's capability. You can use the restimer subroutine to determine the minimum granularity.

Multiple pending timeout requests with the same func and arg parameters are not allowed.

#### The func Parameter

The function specified by the *func* parameter should be declared as follows:

```
void func (arg)
void *arg;
```

### **Execution Environment**

The **timeout** routine can be called from either the process or interrupt environment.

The function specified by the func parameter is called in the interrupt environment. Therefore, it must follow the conventions for interrupt handlers.

### **Return Values**

The timeout service has no return values.

#### **Related Information**

The untimeout kernel service.

The timeoutcf kernel subroutine.

The **restimer** subroutine.

Timer and Time-of-Day Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### timeoutcf Subroutine for Kernel Services

Attention: This service should not be used in AIX® Version 4, because it is not multi-processor safe. The base kernel timer and watchdog services should be used instead. See talloc and w\_init for more information.

## **Purpose**

Allocates or deallocates callout table entries for use with the timeout kernel service.

# Library

libsys.a (Kernel extension runtime routines)

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int timeoutcf ( cocnt)
int cocnt;
```

### **Parameter**

cocnt

Specifies the callout count. This value indicates the number of callout elements by which to increase or decrease the current allocation. If this number is positive, the number of callout entries for use with the timeout service is increased. If this number is negative, the number of elements is decreased by the amount specified.

## **Description**

The timeoutcf subroutine is not part of the kernel. It is a compatibility service provided in the libsys.a library. To use the timeoutcf subroutine, a kernel extension must have been bound with the libsys.a library. The timeoutcf subroutine, like the associated kernel libsys services untimeout and timeout, can be bound and used only in the pinned part of a kernel extension or the bottom half of a device driver because these services use interrupt disable for serialization.

The **timeoutcf** subroutine registers an increase or decrease in the number of callout table entries available for the timeout subroutine to use. Before a subroutine can use the timeout kernel service, the timeoutcf subroutine must increase the number of callout table entries available to the timeout kernel service. It increases this number by the maximum number of outstanding time outs that the routine can have pending at one time.

The timeoutcf subroutine should be used to decrease the amount of callout table entries by the amount it was increased under the following conditions:

- The routine using the timeout subroutine has finished using it.
- The calling routine has no more outstanding time-out requests pending.

Typically the timeoutcf subroutine is called in a device driver's open and close routine. It is called to allocate and deallocate sufficient elements for the maximum expected use of the timeout kernel service for that instance of the open device.

Attention: A kernel panic results under either of these two circumstances:

- · A request to decrease the callout table allocation is made that is greater than the number of unused callout table entries.
- The **timeoutcf** subroutine is called in an interrupt environment.

### **Execution Environment**

The **timeoutcf** subroutine can be called from the process environment only.

### **Return Values**

- 0 Indicates a successful allocation or deallocation of the requested callout table entries.
- -1 Indicates an unsuccessful operation.

### **Related Information**

The timeout kernel service.

Timer and Time-of-Day Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# trc\_ishookon Exported Kernel Service

### **Purpose**

Checks if a given trace hook word is being traced by system trace.

## **Syntax**

```
#include <sys/trcmacros.h>
int trc_ishookon (int chan, long hkwd);
```

## **Description**

The trc\_ishookon kernel service informs the user if tracing is on and the specified hook word is being traced.

### **Parameters**

chan The channel to query with the range from 0 to 7. hkwd The hook word to be traced by system trace.

### **Return Values**

The hook word is being traced.

0 Hook word is not being traced or system trace is off.

### **Related Information**

The trace daemon.

# trcgenk Kernel Service

# **Purpose**

Records a trace event for a generic trace channel.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/trchkid.h>
void trcgenk (chan, hk_word, data_word, len, buf)
unsigned int chan, hk word, data word, len;
char * buf;
```

### **Parameters**

Specifies the channel number for the trace session. This number is obtained from the trcstart chan

subroutine.

hk\_word An integer containing a hook ID and a hook type:

> Before AIX® 6.1 the hook identifier is a 12-bit value. On AIX® 6.1 and above, the hook identifier is a 16-bit value. A 16-bit value of the form hhh0 is equivalent to a 12-bit value of the form hhh.

hk\_type

A 4-bit hook type. The trcgenk service automatically records this information. This value is only valid before AIX® 6.1.

Specifies a word of user-defined data. data word

Specifies the length in bytes of the buffer specified by the buf parameter. len

Points to a buffer of trace data. The maximum amount of trace data is 4096 bytes. buf

## **Description**

The trcgenk kernel service records a trace event if a trace session is active for the specified trace channel. If a trace session is not active, the trcgenk kernel service simply returns. The trcgenk kernel service is located in pinned kernel memory.

The trcgenk kernel service is used to record a trace entry consisting of an hk\_word entry, a data\_word entry, a variable number of bytes of trace data, and, in AIX 5L<sup>™</sup> Version 5.3 with the 5300-05 Technology Level and above, a time stamp.

#### **Execution Environment**

The trcgenk kernel service can be called from either the process or interrupt environment.

### Return Values

The trcgenk kernel service has no return values.

### **Related Information**

The trace daemon.

The **trcgenkt** kernel service.

The trcgen subroutine, trcgent subroutine, trchook subroutine, trcoff subroutine, trcon subroutine, trcstart subroutine, trcstop subroutine.

RAS Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# trcgenkt Kernel Service

# **Purpose**

Records a trace event, including a time stamp, for a generic trace channel.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/trchkid.h>
void trcgenkt (chan, hk_word, data_word, len, buf)
unsigned int chan, hk word, data word, len;
char * buf;
```

### **Parameters**

chan Specifies the channel number for the trace session. This number is obtained from the trestart

subroutine.

hk word An integer containing a hook ID and a hook type:

Before AIX® 6.1 the hook identifier is a 12-bit value. On AIX® 6.1 and above, the hook

identifier is a 16-bit value. A 16-bit value of the form hhh0 is equivalent to a 12-bit value of

the form hhh.

hk\_type

A 4-bit hook type. The trcgenkt service automatically records this information. This value

is only valid before AIX® 6.1.

Specifies a word of user-defined data. data word

len Specifies the length, in bytes, of the buffer identified by the buf parameter.

buf Points to a buffer of trace data. The maximum amount of trace data is 4096 bytes.

## **Description**

The trcgenkt kernel service records a trace event if a trace session is active for the specified trace channel. If a trace session is not active, the trcgenkt service simply returns. The trcgenkt kernel service is located in pinned kernel memory.

The **trcgenkt** service records a trace entry consisting of an hk\_word entry, a data\_word entry, a variable number of bytes of trace data, and a time stamp.

### **Execution Environment**

The trcgenkt kernel service can be called from either the process or interrupt environment.

#### Return Values

The trcgenkt service has no return values.

### **Related Information**

The trace daemon.

The **trcgenk** kernel service.

The trcgen subroutine, trcgent subroutine, trchook subroutine, trcoff subroutine, trcon subroutine, trcstart subroutine, trcstop subroutine.

RAS Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# trcgenkt Kernel Service for Data Link Control (DLC) Devices

# **Purpose**

Records a trace event, including a time stamp, for a DLC trace channel.

# **Syntax**

```
#include <sys/trchkid.h>
```

```
void trcgenkt (chan, hk word, data word, len, buf)
unsigned int chan, hk word, data word, len;
char * buf;
```

### **Parameters**

chan Specifies the channel number for the trace session. This number is obtained from the trcstart

subroutine.

hk\_word Contains the trace hook identifier defined in the /usr/include/sys/trchkid.h file. The types of link

trace entries registered using the hook ID include:

HKWD SYSX DLC START

Start link station completions

HKWD\_SYSX\_DLC\_TIMER

Time-out completions

HKWD SYSX DLC XMIT

Transmit completions

HKWD\_SYSX\_DLC\_RECV

Receive completions

HKWD\_SYSX\_DLC\_HALT

Halt link station completions

data\_word

Specifies trace data format field. This field varies depending on the hook ID. Each of these definitions are in the /usr/include/sys/gdlextcb.h file:

· The first half-word always contains the data link protocol field including one of these definitions:

DLC\_DL\_SDLC

SDLC

DLC\_DL\_HDLC

- · On transmit completion, the second half-word is set to the data link control bytes being sent. Some transmit packets only have a single control byte; in that case, the second control byte is not displayed.
- · On receive completion, the second half-word is set to the data link control bytes that were received. Some receive packets only have a single control byte; in that case, the second control byte is not displayed.

Specifies the length in bytes of the entry specific data specified by the buf parameter.

Specifies the pointer to the entry specific data that consists of:

#### **Start Link Station Completions**

Link station diagnostic tag and the remote station's name and address.

#### **Time-out Completions**

No specific data is recorded.

#### **Transmit Completions**

Either the first 80 bytes or all the transmitted data, depending on the short/long trace option.

#### **Receive Completions**

Either the first 80 bytes or all the received data, depending on the short/long trace option.

#### **Halt Link Station Completions**

Link station diagnostic tag, the remote station's name and address, and the result code.

## **Description**

len buf

The trcgenkt kernel service records a trace event if a trace session is active for the specified trace channel. If a trace session is not active, the trcgenkt kernel service simply returns. The trcgenkt kernel service is located in pinned kernel memory.

The trcgenkt kernel service is used to record a trace entry consisting of an hk\_word entry, a data\_word entry, a variable number of bytes of trace data, and a time stamp.

### **Execution Environment**

The trcgenkt kernel service can be called from either the process or interrupt environment.

### **Return Values**

The trcgenkt kernel service has no return values.

### **Related Information**

The trcgenk kernel service, trcgenkt kernel service.

The trace daemon.

Generic Data Link Control (GDLC) Environment Overview and RAS Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### tstart Kernel Service

### **Purpose**

Submits a timer request.

## Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/timer.h>
void tstart ( t)
struct trb *t;
```

### **Parameter**

Points to a timer request structure.

## **Description**

The **tstart** kernel service submits a timer request with the timer request block specified by the *t* parameter as input. The caller of the tstart kernel service must first call the talloc kernel service to allocate the timer request structure. The caller must then initialize the structure's fields before calling the tstart kernel service.

Once the request has been submitted, the kernel calls the t->func timer function when the amount of time specified by the t->timeout.it value has elapsed. The t->func timer function is called on an interrupt level. Therefore, code for this routine must follow conventions for interrupt handlers.

The tstart kernel service examines the t->flags field to determine if the timer request being submitted represents an absolute request or an incremental one. An absolute request is a request for a time out at the time represented in the it value structure. An incremental request is a request for a time out at the time represented by now, plus the time in the it value structure.

The caller should place time information for both absolute and incremental timers in the itimerstruc t t.it value substructure. The T\_ABSOLUTE absolute request flag is defined in the /usr/include/sys/timer.h file and should be ORed into the t->flag field if an absolute timer request is desired.

Modifications to the system time are added to incremental timer requests, but not to absolute ones. Consider the user who has submitted an absolute timer request for noon on 12/25/88. If a privileged user then modifies the system time by adding four hours to it, then the timer request submitted by the user still occurs at noon on 12/25/88.

By contrast, suppose it is presently 12 noon and a user submits an incremental timer request for 6 hours from now (to occur at 6 p.m.). If, before the timer expires, the privileged user modifies the system time by adding four hours to it, the user's timer request will then expire at 2200 (10 p.m.).

### **Execution Environment**

The tstart kernel service can be called from either the process or interrupt environment.

#### Return Values

The tstart service has no return values.

#### **Related Information**

The **talloc** kernel service, **tfree** kernel service, **tstop** kernel service.

Timer and Time-of-Day Kernel Services and Using Fine Granularity Timer Services and Structures in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## tstop Kernel Service

## **Purpose**

Cancels a pending timer request.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/timer.h>
int tstop (t)
struct trb *t;
```

### **Parameter**

Specifies the pending timer request to cancel.

## **Description**

The **tstop** kernel service cancels a pending timer request. The **tstop** kernel service must be called before a timer request block can be freed with the **tfree** kernel service.

In a multiprocessor environment, the timer function associated with a timer request block may be active on another processor when the tstop kernel service is called. In this case, the timer request cannot be canceled. A multiprocessor-safe driver must therefore check the return code and take appropriate action if the cancel request failed.

In a uniprocessor environment, the call always succeeds. This is untrue in a multiprocessor environment, where the call will fail if the timer is being handled by another processor. Therefore, the function now has a return value, which is set to 0 if successful, or -1 otherwise. Funnelled device drivers do not need to check the return value since they run in a logical uniprocessor environment. Multiprocessor-safe and multiprocessor-efficient device drivers need to check the return value in a loop. In addition, if a driver uses locking, it must release and reacquire its lock within this loop. A delay should be used between the release and reacquiring the lock as shown below:

```
while (tstop(&trp)) {
       release any lock;
       delay some time;
       reacquire_the_lock;
} /* null while loop if locks not used */
```

### **Execution Environment**

The **tstop** kernel service can be called from either the process or interrupt environment.

### **Return Values**

- Indicates that the request was successfully canceled.
- -1 Indicates that the request could not be canceled.

### **Related Information**

The talloc kernel service, tfree kernel service, tstart kernel service.

Timer and Time-of-Day Kernel Services, Using Fine Granularity Timer Services and Structures, Using Multiprocessor-Safe Timer Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## tuning Kernel Service

### **Purpose**

Provides access to the kernel tunable variables through an easily accessible interface.

## **Syntax**

```
typedef enum {
    TH MORE,
    TH EOF
} tmode t;
#define TH_ABORT TH_EOF
typedef int (*tuning_read_t)(tmode_t mode, long *size, char **buf, void *context);
typedef int (*tuning_write_t)(tmode_t mode, long *size, char *buf, void *context);
tinode t *tuning register handler (path, mode, readfunc, writefunc, context)
const char *path;
mode_t mode;
tuning_read_t readfunc;
tuning write t writefunc;
void * context;
tinode *tuning_register_bint32 (path, mode, variable, low, high)
const char *path;
mode t mode;
int32 *variable;
int32 low;
int32 high;
tinode *tuning_register_bint32x (path, rfunc, wfunc, mode, low, high)
const char *path;
mode t mode;
int32 (*rfunc)(void *);
int (*wfunc)(int32, void *);
void *context;
int32 low;
int32 high;

const char *path;
mode_t mode;
uint32 (*rfunc)(void *);
int (*wfunc)(uint32, void *);
void *context;
uint32 low;
uint32 high;
tinode *tuning register bint64 (path, mode, variable, low, high)
const char *path;
mode_t mode;
int64 *variable;
int64 low;
int64 high;
```

```
tinode *tuning_register_bint64x (path, rfunc, wfunc, mode, low, high)
const char *path;
mode t mode;
int6\overline{4} (*rfunc)(void *);
int (*wfunc)(int64, void *);
void *context;
in64 low;
in64 high;
tinode *tuning register buint64 (path, mode, variable, low, high)
const char *path;
mode t mode;
uint64 *variable;
uint64 low;
uint64 high;
tinode *tuning register buint64x (path, rfunc, wfunc, mode, low, high)
const char *path;
mode t mode;
uint\overline{6}4 (*rfunc)(void *);
int (*wfunc)(uint64, void *);
void *context;
uint64 low;
uint64 high;
void tuning deregister (t)
tinode t * \overline{t};
```

## **Description**

The tuning\_register\_handler kernel service is used to add a file at the location specified by the path parameter. When this file is read from or written to, one of the two callbacks passed as parameters to the function is invoked.

Accesses to the file are viewed in terms of streams. A single stream is created by a sequence of one open, one or more reads, and one close on the file. While the file is open by one process, attempts to open the same file by other processes will be blocked unless O NONBLOCK is passed in the flags to the open subroutine.

The *readfunc* callback behaves like a producer function. The function is called when the user attempts to read from the file. The *mode* parameter is equal to **TH\_MORE** unless the user closes the file prematurely. On entry, the size parameter is an integer containing the size of the buffer. The context parameter is the context pointer passed to the registration function. Upon return, size should contain either the actual amount of data returned, or a zero if an end-of-file condition should be returned to the user. The return value of the function can also be used to signal end-of-file, as described below.

Note: It is expected that the readfunc callback has already done any necessary end-of-file cleanup when it returns the end-of-file signal.

If the amount of data returned is nonzero, the buf parameter may be modified to point to a new buffer. If this is done, the callback is responsible for freeing the new buffer.

If the buffer provided by the caller is too small, the caller may instead set buf to NULL. In this case, the size parameter should be modified to indicate the size of the buffer needed. The caller will then re-invoke the callback with a buffer of at least the requested size.

If the user closes the file before the callback indicates end-of-file, the callback will be invoked one last time with mode equal to TH\_ABORT. In this case, the size parameter is equal to 0 on entry, and any data returned is discarded. The callback must reset its state because no further callbacks will be made for this stream.

The writefunc callback behaves as a consumer function and is used when the user attempts to write to the file. The mode parameter is set to **TH EOF** if no further data can be expected on this stream (for example, the user called the close subroutine on the file). Otherwise, mode is set to TH\_MORE. The size parameter contains the size of the data passed in the buffer. The buf parameter is the pointer to the buffer.

Note: There will be zero or more calls with the *mode* parameter set to TH MORE and one call with the mode parameter set to TH\_EOF for every stream.

The buf parameter may change between invocations. Upon return from the callback, the size parameter must be modified to reflect the amount of data consumed from the buffer, and the buffer must not be freed even if all data is consumed. The function is expected to consume data in a linear (first in, first out) fashion. Unconsumed data is present at the beginning of the buffer at the next invocation of the callback. The *size* parameter will include the size of the unconsumed data.

Both callbacks' return values are expected to be zero. If unsuccessful, a positive value will be placed into the errno global variable (with the accompanying indication of an error return from the kernel service). If the return value of a callback is less than 0, end-of-file will be signaled to the user, and the return value will be treated as its unary negation (For example, -1 will be treated like 0). In this case, no further callbacks will be made for this stream.

The tuning\_register\_bint32, tuning\_register\_buint32, tuning\_register\_bint64, and tuning register buint64 kernel services are used to add a file at the location specified by the path parameter that, when read from, will return the ASCII value of the integer variable pointed to by the variable parameter. When written to, this file will set the integer variable to the value whose ASCII value was written, unless that value does not satisfy the relation low <= value < high. In this case, the integer variable is not modified, and an error is returned to the user through an error return of the kernel service during which the invalid attempt is detected (probably either write or close).

The tuning register b\*x functions operate similarly to their non-x variants, but they use a pair of callbacks to retrieve (rfunc) and set (wfunc) the variable. The callback is passed the value (if setting) and the context parameter. This permits more complex operations on read/write, such as serialization and memory allocation and deallocation.

The tuning\_get\_context kernel service returns the context of the registration function used to create the **tinode** t structure referred to by the *argument* parameter.

The tuning register kernel service is the basic interface by which a file can be added to the /proc/sys directory hierarchy. This function is not exported to kernel extensions, and its direct use in the kernel is strongly discouraged. The path parameter contains the path relative to the /proc/sys root at which the file should appear. Intermediate path components are automatically created. The mode parameter contains the UNIX® permissions and the type of the file to be created (as per the **st mode** field of the **stat** struct). If the file type is not specified, it is assumed to be S\_IFREG. In most cases this parameter will be 0644 or 0600. The *vnops* parameter is used to dispatch all operations on the file.

The tuning deregister kernel service is used to remove a file from the /proc/sys directory hierarchy. It is exported to kernel extensions. It should only be used when a specific file's implementation is no longer available. The t parameter is a tinode t structure as returned by tuning register. If the file is currently open, any further access to it after this call returns ESTALE.

#### **Parameters**

Is set to either TH\_EOF if no further data is expected from the user for this change, or TH\_MORE if mode

further data is expected.

size Contains the size of the data passed in the buffer.

Points to the buffer. buf

context Points to the context passed to the registration function.

Specifies the location of the file to be added. path

readfunc Behaves as a producer function.

Retrieves the variable. rfunc wfunc Sets the variable.

writefunc Behaves as a consumer function.

variable Specifies the variable.

high Specifies the maximum value that the *variable* parameter can contain. Specifies the minimum value that the variable parameter can contain. low

A **tinode t** structure as returned by **tuning register**.

### **Return Values**

Upon successful completion, the tuning\_register kernel service returns the newly created tinode\_t structure. If unsuccessful, a NULL value is returned.

## **Examples**

A user of this interface might include the following line in their initialization routine:

tuning var = tuning register buint64 ("fs/jfs2/max readahead", 0644 &j2 max read ahead, 0, 1024);

In this example tuning var is a global variable of type tinode t \*. This causes the fs and fs/jfs2 directories to be created, and a file (pipe) to be created as fs/ifs2/max readahead. The file returns the value of j2\_max\_readahead in ASCII when read. The variable is read at the time of the first read. A write would set the value of the variable, but only at the time of either the first newline being written or a close function being performed. In order to write the variable after reading it, one must close the file and reopen it for write. This file is not seekable.

## ue\_proc\_check Kernel Service

# **Purpose**

Determines if a process is critical to the system.

# **Syntax**

int ue\_proc\_check (pid) pid\_t pid;

# Description

The ue\_proc\_check kernel service determines if a particular process is critical to the system. A critical process is either a kernel process or a process registered as critical by the **ue proc register** system call. A process that is critical will cause the system to terminate if that process has an unrecoverable hardware error associated with the process. Unrecoverable hardware errors associated with a process are determined by the kernel machine check handler on systems that support UE-Gard error processing.

The ue\_proc\_check kernel service should be called only while executing in kernel mode in the user process.

### **Parameters**

pid Specifies the process' ID to be checked as critical.

### **Execution Environment**

The **ue proc check** kernel service can be called from the interrupt environment only.

#### **Return Values**

0 Indicates that the *pid* is not critical. **EINVAL** Indicates that the *pid* is critical.

-1 Indicates that the *pid* parameter is not valid or the process no longer exists.

#### **Related Information**

The "ue\_proc\_register Subroutine."

### ue\_proc\_register Subroutine

### **Purpose**

Registers a process as critical to the system.

## **Syntax**

int ue\_proc\_register (pid, argument)
pid\_t pid;
int argument;

### **Description**

The **ue\_proc\_register** system call registers a particular process as critical to the system. A process that is critical will cause the system to terminate if that process has an unrecoverable hardware error associated with the process. Unrecoverable hardware errors associated with a process are determined by the kernel machine check handler on systems that support UE-Gard error processing.

An execed process from a critical process must register itself to be critical. A fork from a process inherits the critical registration unless the argument is set to **NONCRITFORK**.

If the value of the pid parameter is equal to (pid\_t) 0, the subroutine is registering the calling process.

The **ue\_proc\_register** system call should be called only while executing with root authority in the user process.

#### **Parameters**

pid Specifies the process' ID to be registered critical.

argument Defined in the **sys/proc.h** header file. Can be the following value:

**NONCRITFORK** 

The pid forks are not critical.

### **Execution Environment**

The **ue\_proc\_register** system call can be called from the process environment only.

#### **Return Values**

0 Indicates successful completion.

**EINVAL** Indicates that the *pid* parameter is not valid or the process no longer exists.

**EACCES** Indicates that the caller does not have sufficient authority to alter the *pid* registration.

#### **Related Information**

The "ue\_proc\_unregister Subroutine."

### ue\_proc\_unregister Subroutine

### **Purpose**

Unregisters a process from being critical to the system.

### **Syntax**

```
int ue_proc_register (pid)
pid t \overline{p}id;
```

## **Description**

The ue proc unregister system call unregisters a particular process as being no longer critical to the system. A process that has been previously registered critical will cause the system to terminate if that process has an unrecoverable hardware error associated with the process. Unrecoverable hardware errors associated with a process are determined by the kernel machine check handler on systems that support UE-Gard error processing.

If the value of the pid parameter is equal to (pid\_t) 0, the subroutine is unregistering the calling process.

The ue\_proc\_unregister service should be called only while executing with root authority in the user process.

### **Parameters**

Specifies the process' ID to be unregistered. pid

#### **Execution Environment**

The ue\_proc\_unregister system call can be called from the process environment only.

#### **Return Values**

0 Indicates successful completion.

**EINVAL** Indicates that the pid parameter is not valid or the process no longer exists.

**EACCES** Indicates that the caller does not have sufficient authority to alter the *pid* registration.

#### **Related Information**

The "ue\_proc\_register Subroutine" on page 487.

#### uexadd Kernel Service

### **Purpose**

Adds a systemwide exception handler for catching user-mode process exceptions.

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/except.h>
```

```
void uexadd ( exp)
struct uexcepth *exp;
```

#### **Parameter**

Points to an exception handler structure. This structure must be pinned and is used for registering user-mode process exception handlers. The uexcepth structure is defined in the /usr/include/sys/except.h file.

### **Description**

The **uexadd** kernel service is typically used to install a systemwide exception handler to catch exceptions occurring during execution of a process in user mode. The **uexadd** kernel service adds the exception handler structure specified by the exp parameter, to the chain of exception handlers to be called if an exception occurs while a process is executing in user mode. The last exception handler registered is the first exception handler called for a user-mode exception.

The **uexcepth** structure has:

- A chain element used by the kernel to chain the registered user exception handlers.
- A function pointer defining the entry point of the exception handler being added.

Additional exception handler-dependent information can be added to the end of the structure, but must be pinned.

Attention: The uexcepth structure must be pinned when the uexadd kernel service is called. It must remain pinned and unmodified until after the call to the uexdel kernel service to delete the specified exception handler. Otherwise, the system may crash.

#### **Execution Environment**

The **uexadd** kernel service can be called from the process environment only.

#### **Return Values**

The **uexadd** kernel service has no return values.

#### **Related Information**

The **uexdel** kernel service and User-Mode Exception Handler for the **uexadd** Kernel Service.

User-Mode Exception Handling and Kernel Extension and Device Driver Management Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## User-Mode Exception Handler for the uexadd Kernel Service

## **Purpose**

Handles exceptions that occur while a kernel thread is executing in user mode.

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/except.h>
int func (exp, type, tid, mst)
struct excepth * exp;
```

```
int type;
tid t tid;
struct mstsave * mst;
```

### **Parameters**

exp Points to the excepth structure used to register this exception handler.

mst Points to the current mstsave area for the process. This pointer can be used to access the mstsave area to obtain additional information about the exception.

tid Specifies the thread ID of the kernel thread that was executing at the time of the exception.

Denotes the type of exception that has occurred. This type value is platform-specific. Specific values are type defined in the /usr/include/sys/except.h file.

### **Description**

The user-mode exception handler (exp->func) is called for synchronous exceptions that are detected while a kernel thread is executing in user mode. The kernel exception handler saves exception information in the mstsave area of the structure. For user-mode exceptions, it calls the first exception handler found on the user exception handler list. The exception handler executes in an interrupt environment at the priority level of either INTPAGER or INTIODONE.

If the registered exception handler returns a return code indicating that the exception was handled, the kernel exits from the exception handler without calling additional exception handlers from the list. If the exception handler returns a return code indicating that the exception was not handled, the kernel invokes the next exception handler on the list. The last exception handler in the list is the default handler. This is typically signalling the thread.

The kernel exception handler must not page fault. It should also register an exception handler using the setimpx kernel service if any exception-handling activity can result in an exception. This is important particularly if the exception handler is handling the I/O. If the exception handler did not handle the exception, the return code should be set to the EXCEPT\_NOT\_HANDLED value for user-mode exception handling.

#### **Execution Environment**

The user-mode exception handler for the **uexadd** kernel service is called in the interrupt environment at the INTPAGER or INTIODONE priority level.

#### **Return Values**

**EXCEPT HANDLED** Indicates that the exception was successfully handled. EXCEPT\_NOT\_HANDLED Indicates that the exception was not handled.

#### **Related Information**

The **uexadd** kernel service.

User-Mode Exception Handling and Kernel Extension and Device Driver Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

#### uexblock Kernel Service

### **Purpose**

Makes the currently active kernel thread nonrunnable when called from a user-mode exception handler.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/except.h>
void uexblock ( tid)
tid t *tid;
```

#### **Parameter**

tid Specifies the thread ID of the currently active kernel thread to be put into a wait state.

### **Description**

The **uexblock** kernel service puts the currently active kernel thread specified by the *tid* parameter into a wait state until the uexclear kernel service is used to make the thread runnable again. If the uexblock kernel service is called from the process environment, the tid parameter must specify the current active thread; otherwise the system will crash with a kernel panic.

The **uexblock** kernel service can be used to lazily control user-mode threads access to a shared serially usable resource. Multiple threads can use a serially used resource, but only one process at a time. When a thread attempts to but cannot access the resource, a user-mode exception can be set up to occur. This gives control to an exception handler registered by the uexadd kernel service. This exception handler can then block the thread using the **uexblock** kernel service until the resource is made available. At this time, the **uexclear** kernel service can be used to make the blocked thread runnable.

#### **Execution Environment**

The **uexblock** kernel service can be called from either the process or interrupt environment.

#### Return Values

The **uexblock** service has no return values.

#### **Related Information**

The **uexclear** kernel service.

User-Mode Exception Handling and Kernel Extension and Device Driver Management Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### uexclear Kernel Service

### **Purpose**

Makes a kernel thread blocked by the **uexblock** service runnable again.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/except.h>
void uexclear ( tid)
tid_t *tid;
```

#### **Parameter**

tid Specifies the thread ID of the previously blocked kernel thread to be put into a run state.

## **Description**

The **uexclear** kernel service puts a kernel thread specified by the *tid* parameter back into a runnable state after it was made nonrunnable by the uexblock kernel service. A thread that has been sent a SIGSTOP stop signal is made runnable again when it receives the SIGCONT continuation signal.

The **uexclear** kernel service can be used to lazily control user-mode thread access to a shared serially usable resource. A serially used resource is usable by more than one thread, but only by one at a time. When a thread attempts to access the resource but does not have access, a user-mode exception can be setup to occur.

This setup gives control to an exception handler registered by the uexadd kernel service. Using the uexblock kernel service, this exception handler can then block the thread until the resource is later made available. At that time, the uexclear service can be used to make the blocked thread runnable.

#### **Execution Environment**

The **uexclear** kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The **uexclear** service has no return values.

#### **Related Information**

The **uexblock** kernel service.

User-Mode Exception Handling and Kernel Extension and Device Driver Management Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

#### uexdel Kernel Service

## **Purpose**

Deletes a previously added systemwide user-mode exception handler.

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/except.h>
void uexdel ( exp)
struct uexcepth *exp;
```

#### **Parameter**

Points to the exception handler structure used to add the exception handler with the uexadd kernel service.

## **Description**

The **uexdel** kernel service removes a user-mode exception handler from the systemwide list of exception handlers maintained by the kernel's exception handler.

The **uexdel** kernel service removes the exception handler structure specified by the *exp* parameter from the chain of exception handlers to be called if an exception occurs while a process is executing in user mode. Once the **uexdel** kernel service has completed, the specified exception handler is no longer called. In addition, the **uexcepth** structure can be modified, freed, or unpinned.

### **Execution Environment**

The **uexdel** kernel service can be called from the process environment only.

#### **Return Values**

The **uexdel** kernel service has no return values.

#### **Related Information**

The **uexadd** kernel service.

User-Mode Exception Handling and Kernel Extension and Device Driver Management Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### ufdcreate Kernel Service

## Purpose

Allocates and initializes a file descriptor.

## **Syntax**

```
#include <fcntl.h>
#include <sys/types.h>
#include <sys/file.h>
int ufdcreate (flags, ops, datap, type, fdp, cnp)
int flags;
struct fileops * ops;
void * datap;
short type;
int * fdp;
struct ucred *crp;
```

#### **Parameters**

Specifies the flags to save in a file structure. The file structure is defined in the sys/file.h file. If a read or flags write subroutine is called with the file descriptor returened by this routine, the FREAD and FWRITE flags must be set appropriately. Valid flags are defined in the **fcntl.h** file.

Points to the list of subsystem-supplied routines to call for the file system operations: read/write, ioctl, ops select, fstat, and close. The fileops structure is defined in the sys/file.h file. See "File Operations" for more information.

datap Points to type-dependent structures. The system saves this pointer in the <b>file</b> structure. As a	
	pointer is available to the file operations when they are called.
type	Specifies the unique type value for the <b>file</b> structure. Valid types are listed in the <b>sys/file.h</b> file.
fdp	Points to an integer field where the file descriptor is stored on successful return.
crp	Points to a credentials structure. This pointer is saved in the file struct for use in subsequent operations. It
	must be a valid ucred struct. The crref() kernel service can be used to obtain a ucred struct

### **Description**

The ufdcreate kernel service provides a file interface to kernel extensions. Kernel extensions use this service to create a file descriptor and file structure pair. Also, this service allows kernel extensions to provide their own file descriptor-based system calls, enabling read/write, ioctl, select, fstat, and close operations on objects outside the file system. The ufdcreate kernel services does not require the extension to understand or conform to the synchronization requirements of the logical file system (LFS).

The ufdcreate kernel service provides a file descriptor to the caller and creates the underlying file structure. The caller must include pointers to subsystem-supplied routines for the read/write, ioctl, select, fstat, and close operations. If any of the operations are not needed by the calling subsystem, then the caller must provide a pointer to an appropriate errno value. Typically, the EOPNOTSUPP value is used for this purpose. See "File Operations" for information about the requirements for the subsystem-supplied routines.

### Removing a File Descriptor

There is no corresponding operation to remove a file descriptor (and the attendant structures) created by the ufdcreate kernel service. To remove a file descriptor, use a call to the close subroutine. The close subroutine can be called from a routine or from within the kernel or kernel extension. If the close is not called, the file is closed when the process exits.

Once a call is made to the ufdcreate kernel service, the file descriptor is considered open before the call to the service returns. When a close or exit subroutine is called, the close file operation specified on the call to the ufdcreate interface is called.

## File Operations

The ufdcreate kernel service allows kernel extensions to provide their own file descriptor-based system calls, enabling read/write, ioctl, select, fstat, and close operations on objects outside the file system. The fileops structure defined in the sys/file.h file provides interfaces for these routines.

#### read/write Requirements

The read/write operation manages input and output to the object specified by the fp parameter. The actions taken by this operation are dependent on the object type. The syntax for the operation is as follows:

```
#include <sys/types.h>
#include <sys/uio.h>
int (*fo_rw) (fp, rw, uiop, ext)
struct file *fp;
enum uio rw rw;
struct uio *uiop;
int ext;
```

The parameters have the following values:

#### Value Description

Points to the file structure. This structure corresponds to the file descriptor used on the read or write

Value	Description
rw	Contains a UIO_READ value for a read operation or UIO_WRITE value for a write operation.
uiop	Points to a <b>uio</b> structure. This structure describes the location and size information for the input and output requested. The <b>uio</b> structure is defined in the <b>uio.h</b> file.
ext	Specifies subsystem-dependent information. If the <b>readx</b> or <b>writex</b> subroutine is used, the value passed by the operation is passed through to this subroutine. Otherwise, the value is 0.

If successful, the fo rw operation returns a value of 0. A nonzero return value should be programmed to indicate an error. See the sys/errno.h file for a list of possible values.

Note: On successful return, the uiop->uio resid field must be updated to include the number of bytes of data actually transferred.

#### ioctl Requirements

The ioctl operation provides object-dependent special command processing. The ioctl subroutine performs a variety of control operations on the object associated with the specified open file structure. This subroutine is typically used with character or block special files and returns an error for ordinary files.

The control operation provided by the ioctl operation is specific to the object being addressed, as are the data type and contents of the arg parameter.

The syntax for the ioctl operation is as follows:

```
#include <sys/types.h>
#include <sys/ioctl.h>
int (*fo_ioctl) (fp, cmd, arg, ext, kflag)
struct file *fp;
int cmd, ext, kflag;
caddr t arg;
```

The parameters have the following values:

Value	Description
fp	Points to the file structure. This structure corresponds to the file descriptor used by the ioctl subroutine.
cmd	Defines the specific request to be acted upon by this routine.
arg	Contains data that is dependent on the <i>cmd</i> parameter.
ext	Specifies subsystem-specific information. If the <b>ioctlx</b> subroutine is used, the value passed by the
	application is passed through to this subroutine. Otherwise, the value is 0.
kflag	Determines where the call is made from. The kflag parameter has the value FKERNEL (from the fcntl.h
	file) if this routine is called through the <b>fp_ioctl</b> interface. Otherwise, its value is 0.

If successful, the fo\_ioctl operation returns a value of 0. For errors, the fo\_ioctl operation should return a nonzero return value to indicate an error. Refer to the sys/errno.h file for the list of possible values.

#### select Requirements

The select operation performs a select operation on the object specified by the fp parameter. The syntax for this operation is as follows:

```
#include <sys/types.h>
int (*fo select) (fp, corl, reqevents, rtneventsp, notify)
struct file *fp;
int corl;
ushort reqevents, *rtneventsp;
void (notify) ();
```

The parameters have the following values:

Value Description

Points to the file structure. This structure corresponds to the file descriptor used by the select fp

subroutine.

Specifies the ID used for correlation in the **selnotify** kernel service. corl

regevents Identifies the events to check. The poll and select functions define three standard event flags and

one informational flag. The sys/poll.h file details the event bit definition. See the fp\_select kernel

service for information about the possible flags.

rtneventsp Indicates the returned events pointer. This parameter, passed by reference, indicates the events

that are true at the current time. The returned event bits include the request events and an error

event indicator.

notify Points to a routine to call when the specified object invokes the selnotify kernel service for an

outstanding asynchronous select or poll event request. If no routine is to be called, this parameter

must be null.

If successful, the **fo select** operation returns a value of 0. This operation should return a nonzero return value to indicate an error. Refer to the sys/errno.h file for the list of possible values.

#### fstat Requirements

The fstat operation fills in an **attribute** structure. Depending on the object type specified by the fp parameter, many fields in the structure may not be applicable. The value passed back from this operation is dependent upon both the object type and what any routine that understands the type is expecting. The syntax for this operation is as follows:

```
#include <sys/types.h>
int (*fo fstat) (fp, sbp)
struct file *fp;
struct stat *sbp;
```

The parameters have the following values:

#### Value Description

Points to the file structure. This structure corresponds to the file descriptor used by the stat subroutine. fp

sbp Points to the **stat** structure to be filled in by this operation. The address supplied is in kernel space.

If successful, the fo fstat operation returns a value of 0. A nonzero return value should be programmed to indicate an error. Refer to the sys/errno.h file for the list of possible values.

#### close Requirements

The close operation invalidates routine access to objects specified by the fp parameter and releases any data associated with that access. This operation is called from the close subroutine code when the file structure use count is decremented to 0. For example, if there are multiple accesses to an object (created by the dup, fork, or other subsystem-specific operation), the close subroutine calls the close operation when it determines that there is no remaining access through the file structure being closed.

A file descriptor is considered open once a file descriptor and file structure have been set up by the LFS. The close file operation is called whenever a close or exit is specified. As a result, the close operation must be able to close an object that is not fully open, depending on what the caller did before the file structure was initialized.

The syntax for the close operation is as follows:

```
#include <svs/file.h>
int (*fo close) (fp)
struct file *fp;
```

The parameter is:

fp Points to the file structure. This structure corresponds to the file descriptor used by the close subroutine.

If successful, the fo close operation returns a value of 0. This operation should return a nonzero return value to indicate an error. Refer to the sys/errno.h file for the list of possible values.

### **Execution Environment**

The ufdcreate kernel service can be called from the process environment only.

#### Return Values

If the ufdcreate kernel service succeeds, it returns a value of 0. If the kernel service fails, it returns a nonzero value and sets the errno global variable.

#### **Error Codes**

The ufdcreate kernel service fails if one or more of the following errors occur:

Error Description

**EINVAL** The ops parameter is null, or the **fileops** structure does not have entries for for every operation.

**EMFILE** All file descriptors for the process have already been allocated.

**ENFILE** The system file table is full.

### **Related Information**

The **selnotify** kernel service.

The close subroutine, exit, atexit, or \_exit subroutine, ioctl subroutine, open subroutine, read subroutine, **select** subroutine, **write** subroutine, **fp\_select** subroutine.

Logical File System Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## ufdgetf Kernel Service

## **Purpose**

Returns a pointer to a file structure associated with a file descriptor.

## **Syntax**

```
#include <sys/file.h>
int ufdgetf( fd, fpp)
int fd;
struct file **fpp;
```

#### **Parameters**

fd Identifies the file descriptor. The descriptor must be for an open file.

Points to a location to store the file pointer. fpp

### **Description**

The **ufdgetf** kernel service returns a pointer to a file structure associated with a file descriptor. The calling routine must have a use count on the file descriptor. To obtain a use count on the file descriptor, the caller must first call the ufdhold kernel service.

#### **Execution Environment**

The **ufdget** kernel service can be called from the process environment only.

#### **Return Values**

Indicates successful completion.

**EBADF** Indicates that the fd parameter is not a file descriptor for an open file.

#### **Related Information**

The ufdhold kernel service.

### ufdhold and ufdrele Kernel Service

### **Purpose**

Increment or decrement a file descriptor reference count.

### **Syntax**

int ufdhold( fd) int fd; int ufdrele(fd) int fd;

#### **Parameter**

fd Identifies the file descriptor.

## **Description**

Attention: It is extremely important that the calls to ufdhold and ufdrele kernel service are balanced. If a file descriptor is held more times than it is released, the close subroutine on the descriptor never completes. The process hangs and cannot be killed. If the descriptor is released more times than it is held, the system panics.

The **ufdhold** and **ufdrele** kernel services increment and decrement a file-descriptor reference count. Together, these kernel services maintain the file descriptor reference count. The ufdhold kernel service increments the count. The ufdrele kernel service decrements the count.

These subroutines are supported for kernel extensions that provide their own file-descriptor-based system calls. This support is required for synchronization with the close subroutine.

When a thread is executing a file-descriptor-based system call, it is necessary that the logical file system (LFS) be aware of it. The LFS uses the count in the file descriptor to monitor the number of system calls currently using any particular file descriptor. To keep the count accurately, any thread using the file descriptor must increment the count before performing any operation and decrement the count when all activity using the file descriptor is completed for that system call.

#### **Execution Environment**

These kernel services can be called from the process environment only.

#### **Return Values**

0 Indicates successful completion.

**EBADF** Indicates that the *fd* parameter is not a file descriptor for an open file.

#### **Related Information**

The ufdgetf kernel service.

The **close** subroutine.

### uiomove Kernel Service

### **Purpose**

Moves a block of data between kernel space and a space defined by a uio structure.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/uio.h>

int uiomove ( cp, n, rw, uiop)
caddr_t cp;
int n;
uio_rw rw;
struct uio *uiop;
```

#### **Parameters**

cp Specifies the address in kernel memory to or from which data is moved.

*n* Specifies the number of bytes to move.

rw Indicates the direction of the move:

**UIO READ** 

Copies data from kernel space to space described by the **uio** structure.

**UIO\_WRITE** 

Copies data from space described by the **uio** structure to kernel space.

*uiop* Points to a **uio** structure describing the buffer used in the data transfer.

# Description

The **uiomove** kernel service moves the specified number of bytes of data between kernel space and a space described by a **uio** structure. Device driver top halves, especially character device drivers, frequently use the **uiomove** service to transfer data into or out of a user area. The uio\_resid and uio\_iovent fields in the **uio** structure describing the data area must be greater than 0 or an error is returned.

The **uiomove** service moves the number of bytes of data specified by either the *n* or *uio\_resid* parameter, whichever is less. If either the *n* or *uio\_resid* parameter is 0, no data is moved. The uio\_segflg field in the **uio** structure is used to indicate if the move is accessing a user- or kernel-data area, or if the caller

requires cross-memory operations and has provided the required cross-memory descriptors. If a cross-memory operation is indicated, there must be a cross-memory descriptor in the uio\_xmem array for each iovec element.

If the move is successful, the following fields in the **uio** structure are updated:

Field	Description
uio_iov	Specifies the address of current iovec element to use.
uio_xmem	Specifies the address of the current xmem element to use.
uio_iovcnt	Specifies the number of remaining iovec elements.
uio_iovdcnt	Specifies the number of already processed iovec elements.
uio_offset	Specifies the character offset on the device performing the I/O.
uio_resid	Specifies the total number of characters remaining in the data area described by the <b>uio</b> structure.
iov_base	Specifies the address of the data area described by the current iovec element.
iov_len	Specifies the length of remaining data area in the buffer described by the current iovec element.

### **Execution Environment**

The **uiomove** kernel service can be called from the process environment only.

#### **Return Values**

Indicates successful completion.

ENOMEM Indicates that there was no room in the buffer. EIO Indicates a permanent I/O error file space.

ENOSPC Indicates insufficient disk space.

**EFAULT** Indicates a user location that is not valid.

#### **Related Information**

The uphysio kernel service, ureadc kernel service, uwritec kernel service.

## unlock enable Kernel Service

## **Purpose**

Unlocks a simple lock if necessary, and restores the interrupt priority.

## **Syntax**

```
#include <sys/lock_def.h>
void unlock_enable ( int pri, lock addr)
int int pri;
simple_lock_t lock addr;
```

#### **Parameters**

Specifies the interrupt priority to restore. This must be set to the value returned by the int\_pri

corresponding call to the disable\_lock kernel service.

lock\_addr Specifies the address of the lock word to unlock.

### **Description**

The **unlock enable** kernel service unlocks a simple lock if necessary, and restores the interrupt priority, in order to provide optimized thread-interrupt critical section protection for the system on which it is executing. On a multiprocessor system, calling the unlock enable kernel service is equivalent to calling the simple\_unlock and i\_enable kernel services. On a uniprocessor system, the call to the simple unlock service is not necessary, and is omitted. However, you should still pass the valid lock address which was used with the corresponding call to the disable\_lock kernel service. Never pass a **NULL** lock address.

#### **Execution Environment**

The **unlock** enable kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The unlock enable kernel service has no return values.

#### Related Information

The disable lock kernel service, i enable kernel service, simple unlock kernel service.

Understanding Locking, Locking Kernel Services, Understanding Interrupts, I/O Kernel Services, Interrupt Environment in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### unlockl Kernel Service

### Purpose

Unlocks a conventional process lock.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
void unlockl ( lock word)
lock t *lock word;
```

#### **Parameter**

Specifies the address of the lock word. lock word

## **Description**

Note: The unlockl kernel service is provided for compatibility only and should not be used in new code, which should instead use simple locks or complex locks.

The unlockl kernel service unlocks a conventional lock. Only the owner of a lock can unlock it. Once a lock is unlocked, the highest priority thread (if any) which is waiting for the lock is made runnable and may compete again for the lock. If there was at least one process waiting for the lock, the priority of the caller is recomputed. Preempting a System Call discusses how system calls can use locking kernel services when accessing global data.

The lockl and unlockl services do not maintain a nesting level count. A single call to the unlockl service unlocks the lock for the caller. The return code from the **lock!** service should be used to determine when to unlock the lock.

Note: The unlockl kernel service can be called with interrupts disabled, only if the event or lock word is pinned.

#### **Execution Environment**

The unlockl kernel service can be called from the process environment only.

#### **Return Values**

The unlockl service has no return values.

## Example

A call to the unlockl service can be coded as follows:

```
and was initialized to
                      LOCK_AVAIL */
/* get lock prior to using resource */
lock ret = lock1(lock word, LOCK SHORT)
/* use resource for which lock was obtained */
/* release lock if this was not a nested use */
if ( lock ret != LOCK NEST )
  unlockl(lock word);
```

#### Related Information

The lockl kernel service.

## unpin Kernel Service

## **Purpose**

Unpins the address range in system (kernel) address space.

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pin.h>
int unpin ( addr, length)
caddr addr;
int length;
```

#### **Parameters**

addr Specifies the address of the first byte to unpin in the system (kernel) address space.

Specifies the number of bytes to unpin. length

### **Description**

The **unpin** kernel service decreases the pin count of each page in the address range. When the pin count is 0, the page is not pinned and can be paged out of real memory. Upon finding an unpinned page, the unpin service returns the EINVAL error code and leaves any remaining pinned pages still pinned.

The unpin service can only be called with addresses in the system (kernel) address space. The **xmemunpin** service should be used where the address space might be in either user or kernel space.

#### **Execution Environment**

The **unpin** kernel service can be called from either the process or interrupt environment.

#### **Return Values**

Indicates successful completion.

**EINVAL** Indicates that the value of the *length* parameter is negative or 0. Otherwise, the area of memory

beginning at the byte specified by the base parameter and extending for the number of bytes specified by the len parameter is not defined. If neither cause is responsible, an unpinned page was specified.

#### **Related Information**

The pin, xmempin, and xmemunpin kernel services.

Understanding Execution Environments and Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## unpincode Kernel Service

## Purpose

Unpins the code and data associated with a loaded object module.

## **Syntax**

```
#include <svs/tvpes.h>
#include <sys/errno.h>
#include <sys/pin.h>
int unpincode ( func)
int (*func) ();
```

#### **Parameter**

func Specifies an address used to determine the object module to be unpinned. The address is typically that of a function that is exported by this object module.

## **Description**

The unpincode kernel service uses the Itunpin kernel service to decrement the pin count for the pages associated with the following items:

- Code associated with the object module
- Data area of the object module that contains the function specified by the func parameter

The loader entry for the module is used to determine the size of both the code and the data area.

#### **Execution Environment**

The unpincode kernel service can be called from the process environment only.

#### **Return Values**

Indicates successful completion.

**EINVAL** Indicates that the func parameter is not a valid pointer to the function.

**EFAULT** Indicates that the calling process does not have access to the area of memory that is associated with the

module.

#### **Related Information**

The unpin kernel service.

Understanding Execution Environments and Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## unregister\_HA\_handler Kernel Service

### **Purpose**

Removes from the kernel the registration of a High Availability Event Handler.

### **Syntax**

#include <sys/high avail.h>

int register HA handler (ha handler) ha\_handler\_ext\_t \* ha\_handler;

#### **Parameter**

ha\_handler

Specifies a pointer to a structure of the type ha\_handler\_ext\_t defined in /usr/include/sys/ high\_avail.h. This structure must be identical to the one passed to register\_HA\_handler at the time of registration.

## **Description**

The unregister HA handler kernel service cancels an unconfigured kernel extensions that have registered a high availability event handler, done by the register\_HA\_handler kernel service, so that the kernel extension can be unloaded.

Failure to do so may cause a system crash when a high availability event such as a processor deallocation is initiated due to some hardware fault.

#### **Execution Environment**

The unregister\_HA\_handler kernel service can be called from the process environment only.

An extension may register the same HAEH N times (N > 1). Although this is considered an incorrect behaviour, no error is reported. The given HAEH will be invoked N times for each HA event. This handler has to be unregistered as many times as it was registered.

Indicates a successful operation.

#### **Return Values**

A non-zero value indicates an error.

### **Related Information**

The register HA handler kernel service.

The RAS Kernel Services in the AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

#### untimeout Kernel Service

Attention: This service should not be used in AIX® Version 4, because it is not multi-processor safe. The base kernel timer and watchdog services should be used instead. See talloc and w init for more information.

### **Purpose**

Cancels a pending timer request.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
void untimeout ( func, arg)
void (*func)();
caddr_t *arg;
```

#### **Parameters**

func Specifies the function associated with the timer to be canceled.

Specifies the function argument associated with the timer to be canceled. arg

## **Description**

The **untimeout** kernel service is not part of the kernel. However, it is a compatibility service provided in the libsys.a library. To use the untimeout service, a kernel extension must have been bound with the libsys.a library. The untimeout service, like the associated kernel libsys services timeoutcf and timeout, can be bound and used only in the pinned part of a kernel extension or the bottom half of a device driver because these services use interrupt disable for serialization.

The untimeout kernel service cancels a specific request made with the timeout service. The func and arg parameters must match those used in the timeout kernel service request that is to be canceled.

Upon return, the specified timer request is canceled, if found. If no timer request matching func and arg is found, no operation is performed.

#### **Execution Environment**

The untimeout kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The untimeout kernel service has no return values.

#### **Related Information**

The timeout kernel service.

Timer and Time-of-Day Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## uphysio Kernel Service

## **Purpose**

Performs character I/O for a block device using a uio structure.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
#include <sys/uio.h>
int uphysio (uiop, rw, buf cnt, devno, strat, mincnt, minparms)
struct uio * uiop;
int rw;
uint buf_cnt;
dev t devno;
int (* strat)();
int (* mincnt)();
void * minparms;
```

### **Parameters**

uiop

•	using character-to-block I/O.
rw	Indicates either a read or write operation. A value of <b>B_READ</b> for this flag indicates a read operation. A value of <b>B_WRITE</b> for this flag indicates a write operation.
buf_cnt	Specifies the maximum number of <b>buf</b> structures to use when calling the strategy routine specified by the <i>strat</i> parameter. This parameter is used to indicate the maximum amount of concurrency the device can support and minimize the I/O redrive time. The value

of the buf\_cnt parameter can range from 1 to 64. Specifies the major and minor device numbers. With the uphysio service, this parameter specifies the device number to be placed in the buf structure before calling the strategy routine specified by the

Points to the uio structure describing the buffer of data to transfer

strat parameter.

Represents the function pointer to the ddstrategy routine for the

device.

mincnt

strat

devno

Represents the function pointer to a routine used to reduce the data transfer size specified in the buf structure, as required by the device before the strategy routine is started. The routine can also be used to update extended parameter information in the buf structure before the information is passed to the strategy routine. Points to parameters to be used by the *mincnt* parameter.

minparms

## **Description**

The **uphysio** kernel service performs character I/O for a block device. The **uphysio** service attempts to send to the specified strategy routine the number of **buf** headers specified by the *buf\_cnt* parameter. These **buf** structures are constructed with data from the **uio** structure specified by the *uiop* parameter.

The **uphysio** service initially transfers data area descriptions from each iovec element found in the **uio** structure into individual **buf** headers. These headers are later sent to the strategy routine. The **uphysio** kernel service tries to process as many data areas as the number of buf headers permits. It then invokes the strategy routine with the list of **buf** headers.

### **Preparing Individual buf Headers**

The routine specified by the *mincnt* parameter is called before the **buf** header, built from an iovec element, is added to the list of **buf** headers to be sent to the strategy routine. The *mincnt* parameter is passed a pointer to the **buf** header along with the *minparms* pointer. This arrangement allows the *mincnt* parameter to tailor the length of the data transfer described by the buf header as required by the device performing the I/O. The mincnt parameter can also optionally modify certain device-dependent fields in the buf header.

When the *mincnt* parameter returns with no error, an attempt is made to pin the data buffer described by the buf header. If the pin operation fails due to insufficient memory, the data area described by the buf header is reduced by half. The **buf** header is again passed to the *mincnt* parameter for modification before trying to pin the reduced data area.

This process of downsizing the transfer specified by the buf header is repeated until one of the three following conditions occurs:

- · The pin operation succeeds.
- The *mincnt* parameter indicates an error.
- The data area size is reduced to 0.

When insufficient memory indicates a failed pin operation, the number of buf headers used for the remainder of the operation is reduced to 1. This is because trying to pin multiple data areas simultaneously under these conditions is not desirable.

If the user has not already obtained cross-memory descriptors, further processing is required. (The uio segflg field in the uio structure indicates whether the user has already initialized the cross-memory descriptors. The usr/include/sys/uio.h file contains information on possible values for this flag.)

When the data area described by the **buf** header has been successfully pinned, the **uphysio** service verifies user access authority for the data area. It also obtains a cross-memory descriptor to allow the device driver interrupt handler limited access to the data area.

#### Calling the Strategy Routine

After the uphysio kernel service obtains a cross-memory descriptor to allow the device driver interrupt handler limited access to the data area, the buf header is then put on a list of buf headers to be sent to the strategy routine specified by the strat parameter.

The strategy routine specified by the *strat* parameter is called with the list of **buf** headers when:

- The list reaches the number of buf structures specified by the buf cnt parameter.
- The data area described by the **uio** structure has been completely described by **buf** headers.

The buf headers in the list are chained together using the av back and av forw fields before they are sent to the strategy routine.

### Waiting for buf Header Completion

When all available buf headers have been sent to the strategy routine, the uphysio service waits for one or more of the buf headers to be marked complete. The IODONE handler is used to wake up the uphysio service when it is waiting for completed **buf** headers from the strategy routine.

When the **uphysio** service is notified of a completed **buf** header, the associated data buffer is unpinned and the cross-memory descriptor is freed. (However, the cross-memory descriptor is freed only if the user had not already obtained it.) An error is detected on the data transfer under the following conditions:

- The completed **buf** header has a nonzero b resid field.
- The b flags field has the B ERROR flag set.

When an error is detected by the **uphysio** service, no new **buf** headers are sent to the strategy routine.

The **uphysio** service waits for any **buf** headers already sent to the strategy routine to be completed and then returns an error code to the caller. If no errors are detected, the buf header and any other completed buf headers are again used to send more data transfer requests to the strategy routine as they become available. This process continues until all data described in the uio structure has been transferred or until an error has been detected.

The **uphysio** service returns to the caller when:

- All **buf** headers have been marked complete by the strategy routine.
- All data specified by the uio structure has been transferred.

The uphysio service also returns an error code to the caller if an error is detected.

#### Error Detection by the uphysio Kernel Service

When it detects an error, the uphysio kernel service reports the error that was detected closest to the start of the data area described by the uio structure. No additional buf headers are sent to the strategy routine. The **uphysio** kernel service waits for all **buf** headers sent to the strategy routine to be marked complete.

However, additional **buf** headers may have been sent to the strategy routine between these two events:

- · After the strategy routine detects the error.
- Before the uphysio service is notified of the error condition in the completed buf header.

When errors occur, various fields in the returned **uio** structure may or may not reflect the error. The uio iov and uio iovcnt fields are not updated and contain their original values.

The uio resid and uio offset fields in the returned uio structure indicate the number of bytes transferred by the strategy routine according to the sum of all (the b bcount field minus the b resid fields) fields in the buf headers processed by the strategy routine. These headers include the buf header indicating the error nearest the start of the data area described by the original uio structure. Any data counts in buf headers completed after the detection of the error are not reflected in the returned uio structure.

#### **Execution Environment**

The **uphysio** kernel service can be called from the process environment only.

#### **Return Values**

Indicates successful completion.

**ENOMEM** Indicates that no memory is available

for the required buf headers.

**EAGAIN** Indicates that the operation fails due to

a temporary insufficient resource

condition.

**EFAULT** Indicates that the uio segflg field

indicated user space and that the user does not have authority to access the

buffer.

EIO or the b error field in a buf header Indicates an I/O error in a buf header

processed by the strategy routine. Indicates that the return code from the mincnt parameter if the routine

returned with a nonzero return code.

## **Related Information**

The **ddstrategy** device driver entry point.

Return code from the mincnt parameter

The **geterror** kernel service, **iodone** kernel service.

The **mincnt** routine.

The **buf** structure, **uio** structure.

# uphysio Kernel Service mincnt Routine

## **Purpose**

Tailors a **buf** data transfer request to device-dependent requirements.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
int mincnt ( bp, minparms)
struct buf *bp;
void *minparms;
```

#### **Parameters**

Points to the **buf** structure to be tailored.

minparms Points to parameters.

## **Description**

Only the following fields in the buf header sent to the routine specified by the uphysio kernel service mincnt parameter can be modified by that routine:

- b bcount
- b\_work
- b\_options

The mincnt parameter cannot modify any other fields without the risk of error. If the mincnt parameter determines that the buf header cannot be supported by the target device, the routine should return a nonzero return code. This stops the buf header and any additional buf headers from being sent to the ddstrategy routine.

The uphysio kernel service waits for all buf headers already sent to the strategy routine to complete and then returns with the return code from the *mincnt* parameter.

#### **Related Information**

The uphysio kernel service.

## uprintf Kernel Service

### **Purpose**

Submits a request to print a message to the controlling terminal of a process.

```
#include <sys/uprintf.h>
int uprintf ( Format [, Value, ...])
char *Format;
```

#### **Parameters**

Format

Specifies a character string containing either or both of two types of objects:

- · Plain characters, which are copied to the message output stream.
- Conversion specifications, each of which causes 0 or more items to be retrieved from the Value parameter list. Each conversion specification consists of a % (percent sign) followed by a character that indicates the type of conversion to be applied:
  - % Performs no conversion. Prints %.
  - d. i Accepts an integer Value and converts it to signed decimal notation.
  - Accepts an integer Value and converts it to unsigned decimal notation. u
  - Accepts an integer Value and converts it to unsigned octal notation. 0
  - Accepts an integer Value and converts it to unsigned hexadecimal notation. X
  - Accepts a Value as a string (character pointer), and characters from the string are printed until a \ 0 (null character) is encountered. Value must be non-null and the maximum length of the string is limited to **UP\_MAXSTR** characters.

Field width or precision conversion specifications are not supported.

The following constants are defined in the /usr/include/sys/uprintf.h file:

- UP\_MAXSTR
- UP MAXARGS
- UP MAXCAT
- UP MAXMSG

The Format string may contain from 0 to the number of conversion specifications specified by the **UP\_MAXARGS** constant. The maximum length of the *Format* string is the number of characters specified by the UP\_MAXSTR constant. Format must be non-null.

The maximum length of the constructed kernel message is limited to the number of characters specified by the UP\_MAXMSG constant. Messages larger then the number of characters specified by the **UP\_MAXMSG** constant are discarded.

Value

Specifies, as an array, the value to be converted. The number, type, and order of items in the Value parameter list should match the conversion specifications within the Format string.

## **Description**

The uprintf kernel service submits a kernel message request. Once the request has been successfully submitted, the uprintfd daemon constructs the message based on the Format and Value parameters of the request. The **uprintfd** daemon then writes the message to the process' controlling terminal.

#### **Execution Environment**

The **uprintf** kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

ENOMEM Indicates that memory is not available to buffer the request. **ENODEV** Indicates that a controlling terminal does not exist for the process.

**ESRCH** Indicates that the uprintfd daemon is not active. No requests may be submitted.

**EINVAL** Indicates that a string Value string pointer is null or the string Value parameter is greater than the number

of characters specified by the UP\_MAXSTR constant.

#### EINVAL

Indicates one of the following:

- · Format string pointer is null.
- · Number of characters in the Format string is greater than the number specified by the UP\_MAXSTR constant.
- Number of conversion specifications contained within the Format string is greater than the number specified by the **UP\_MAXARGS** constant.

#### **Related Information**

The NLuprintf kernel service.

The **uprintfd** daemon.

Process and Exception Management Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

#### ureadc Kernel Service

### **Purpose**

Writes a character to a buffer described by a uio structure.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/uio.h>
int ureadc ( c, uiop)
int c:
struct uio *uiop;
```

#### **Parameters**

Specifies a character to be written to the buffer.

Points to a **uio** structure describing the buffer in which to place a character. aoiu

## **Description**

The **ureadc** kernel service writes a character to a buffer described by a **uio** structure. Device driver top half routines, especially character device drivers, frequently use the ureadc kernel service to transfer data into a user area.

The uio resid and uio iovent fields in the **uio** structure describing the data area must be greater than 0. If these fields are not greater than 0, an error is returned. The uio segflg field in the uio structure is used to indicate whether the data is being written to a user- or kernel-data area. It is also used to indicate if the caller requires cross-memory operations and has provided the required cross-memory descriptors. The values for the flag are defined in the /usr/include/sys/uio.h file.

If the data is successfully written, the following fields in the uio structure are updated:

Field	Description
uio_iov	Specifies the address of current iovec element to use.
uio_xmem	Specifies the address of current xmem element to use (used for cross-memory copy).
uio_iovcnt	Specifies the number of remaining iovec elements.

Field **Description** uio iovdcnt Specifies the number of iovec elements already processed. uio offset Specifies the character offset on the device from which data is read. uio resid Specifies the total number of characters remaining in the data area described by the uio iov base Specifies the address of the next available character in the data area described by the current iovec element. iov\_len Specifies the length of remaining data area in the buffer described by the current iovec element.

### **Execution Environment**

The **ureadc** kernel service can be called from the process environment only.

#### **Return Values**

Indicates successful completion.

**ENOMEM** Indicates that there is no room in the buffer.

**EFAULT** Indicates that the user location is not valid for one of these reasons:

- The uio segflg field indicates user space and the base address (iov base field) points to a location outside of the user address space.
- · The user does not have sufficient authority to access the location.
- · An I/O error occurs while accessing the location.

#### **Related Information**

The **uiomove** kernel service, **uphysio** kernel service, **uwritec** kernel service.

The **uio** structure.

Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

#### uwritec Kernel Service

## **Purpose**

Retrieves a character from a buffer described by a uio structure.

## **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/uio.h> int uwritec ( uiop) struct uio \*uiop;

#### **Parameter**

uiop Points to a **uio** structure describing the buffer from which to read a character.

### **Description**

The **uwritec** kernel service reads a character from a buffer described by a **uio** structure. Device driver top half routines, especially character device drivers, frequently use the **uwritec** kernel service to transfer data out of a user area. The uio\_resid and uio\_iovcnt fields in the **uio** structure must be greater than 0 or an error is returned.

The uio\_segflg field in the **uio** structure indicates whether the data is being read out of a user- or kernel-data area. This field also indicates whether the caller requires cross-memory operations and has provided the required cross-memory descriptors. The values for this flag are defined in the **/usr/include/sys/uio.h** file.

If the data is successfully read, the following fields in the uio structure are updated:

Field	Description
uio_iov	Specifies the address of the current iovec element to use.
uio_xmem	Specifies the address of the current xmem element to use (used for cross-memory copy).
uio_iovcnt	Specifies the number of remaining iovec elements.
uio_iovdcnt	Specifies the number of iovec elements already processed.
uio_offset	Specifies the character offset on the device to which data is written.
uio_resid	Specifies the total number of characters remaining in the data area described by the <b>uio</b> structure.
iov_base	Specifies the address of the next available character in the data area described by the current i ovec element.
iov_len	Specifies the length of the remaining data in the buffer described by the current iovec element.

#### **Execution Environment**

The **uwritec** kernel service can be called from the process environment only.

#### **Return Values**

Upon successful completion, the uwritec service returns the character it was sent to retrieve.

- -1 Indicates that the buffer is empty or the user location is not valid for one of these three reasons:
  - The uio\_segflg field indicates user space and the base address (iov\_base field) points to a location outside of the user address space.
  - · The user does not have sufficient authority to access the location.
  - An I/O error occurred while the location was being accessed.

#### **Related Information**

The uiomove kernel service, uphysio kernel service, ureadc kernel service.

## validate\_pag or validate\_pag64 Kernel Service

## **Purpose**

Validates the Process Authentication Group (PAG) value.

```
#include <sys/cred.h>
int validate_pag ( type, pg, npags )
int type;
struct paglist pg[];
int npags;
```

```
int validate pag64 ( type, pg, npags )
int type;
struct paglist64 pg[];
int npags;
```

#### **Parameters**

type PAG type to validate

PAG list (must be in pinned memory) pg

npags Number of PAGs to validate

## **Description**

The validate\_pag or validate\_pag64 kernel service validates the PAGs specified in pg. These services support the garbage collection of data structures by kernel extensions associated with PAGs. These structures are associated with a set pag interface process. PAG values are inherited from parent to child across the fork system call, so one kernel extension structure can map to many processes. This routine is required to synchronize the execution of forks so that the process table can be scanned to identify a particular PAG. The validate\_pag and validate\_pag64 kernel services cannot be used simultaneously with the **set pag** interface. The application is required to provide this synchronization.

The value of type must be a defined PAG ID. The PAG ID for the Distributed Computing Environment (DCE) is 0. The pg parameter must be a valid, referenced PAG list in pinned memory.

#### **Execution Environment**

The validate pag and validate pag64 kernel services can be called from the process environment only.

#### **Return Values**

A value of 0 is returned upon successful completion. Upon failure, a -1 is returned and errno is set to a value that explains the error.

#### **Error Codes**

The validate pag and validate pag64 kernel services fail if the following condition is true:

**EINVAL** Invalid PAG specification

#### **Related Information**

Security Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vec\_clear Kernel Service

## **Purpose**

Removes a virtual interrupt handler.

```
#include <sys/types.h>
#include <sys/errno.h>
void vec clear ( levsublev)
int levsublev;
```

#### **Parameter**

levsublev

Represents the value returned by vec\_init kernel service when the virtual interrupt handler was defined

### **Description**

The **vec clear** kernel service is not part of the base kernel but is provided by the device queue management kernel extension. This queue management kernel extension must be loaded into the kernel before loading any kernel extensions referencing these services.

The vec\_clear kernel service removes the association between a virtual interrupt handler and the virtual interrupt level and sublevel that was assigned by the vec\_init kernel service. The virtual interrupt handler at the sublevel specified by the levsublev parameter no longer registers upon return from this routine.

#### **Execution Environment**

The vec\_clear kernel service can be called from the process environment only.

#### **Return Values**

The vec\_clear kernel service has no return values. If no virtual interrupt handler is registered at the specified sublevel, no operation is performed.

#### **Related Information**

The vec init kernel service.

### vec init Kernel Service

## **Purpose**

Defines a virtual interrupt handler.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int vec_init ( level, routine, arg)
int level:
void (*routine) ();
int arg;
```

#### **Parameters**

level Specifies the virtual interrupt level. This level value is not used by the vec\_init kernel service and

implies no relative priority. However, it is returned with the sublevel assigned for the registered virtual

interrupt handler.

routine Identifies the routine to call when a virtual interrupt occurs on a given interrupt sublevel.

Specifies a value that is passed to the virtual interrupt handler. arg

## **Description**

The vec\_init kernel service is not part of the base kernel but provided by the device queue management kernel extension. This queue management kernel extension must be loaded into the kernel before loading any kernel extensions referencing these services.

The vec init kernel service associates a virtual interrupt handler with a level and sublevel. This service searches the available sublevels to find the first unused one. The routine and arg parameters are used to initialize the open sublevel. The vec\_init kernel service then returns the level and assigned sublevel.

There is a maximum number of available sublevels. If this number is exceeded, the vec\_init service halts the system. This service should be called to initialize a virtual interrupt before any device gueues using the virtual interrupt are created.

The *level* parameter is not used by the **vec\_init** service. It is provided for compatibility reasons only. However, its value is passed back intact with the sublevel.

#### **Execution Environment**

The **vec\_init** kernel service can be called from the process environment only.

#### **Return Values**

The **vec** init kernel service returns a value that identifies the virtual interrupt level and assigned sublevel. The low-order 8 bits of this value specify the sublevel, and the high-order 8 bits specify the level. The attchg kernel service uses the same format. This level value is the same value as that supplied by the level parameter.

### vfsrele Kernel Service

### Purpose

Releases all resources associated with a virtual file system.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int vfsrele ( vfsp)
struct vfs *vfsp;
```

#### **Parameter**

vfsp Points to a virtual file system structure.

## **Description**

The **vfsrele** kernel service releases all resources associated with a virtual file system.

When a file system is unmounted, the VFS UNMOUNTED flag is set in the vfs structure, indicating that it is no longer valid to do path name-related operations within the file system. When this flag is set and a vnop rele v-node operation releases the last active v-node within the file system, the vnop rele v-node implementation must call the **vfsrele** kernel service to complete the deallocation of the **vfs** structure.

#### **Execution Environment**

The vfsrele kernel service can be called from the process environment only.

#### **Return Values**

The **vfsrele** kernel service always returns a value of 0.

#### **Related Information**

Virtual File System Overview, Virtual File System (VFS) Kernel Services, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

#### vm att Kernel Service

### **Purpose**

Maps a specified virtual memory object to a region in the current address space.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
caddr_t vm_att ( vmhandle, offset)
vmhandle t vmhandle;
caddr_t offset;
```

#### **Parameters**

vmhandle Specifies the handle for the virtual memory object to be mapped. offset Specifies the offset in the virtual memory object and region.

## **Description**

The vm\_att kernel service performs the following tasks:

- Selects an unallocated region in the current address space and allocates it.
- Maps the virtual memory object specified by the vmhandle parameter with the access permission specified in the handle.
- Constructs the address in the current address space corresponding to the offset in the virtual memory object and region.

The vm\_att kernel service assumes an address space model of fixed-size virtual memory objects and address space regions.

Attention: If there are no more free regions, this call cannot complete and calls the panic kernel service.

#### **Execution Environment**

The vm\_att kernel service can be called from either the process or interrupt environment.

#### **Return Values**

The vm att kernel service returns the address that corresponds to the offset parameter in the address space.

#### **Related Information**

The as\_geth kernel service, vm\_det kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vm\_cflush Kernel Service

### **Purpose**

Flushes the processor's cache for a specified address range.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
void vm cflush ( eaddr, nbytes)
caddr_t eaddr;
int nbytes;
```

#### **Parameters**

eaddr Specifies the starting address of the specified range.

Specifies the number of bytes in the address range. If this parameter is negative or 0, no lines are nbytes

invalidated.

## **Description**

The vm\_cflush kernel service writes to memory all modified cache lines that intersect the address range (eaddr, eaddr + nbytes -1). The eaddr parameter can have any alignment in a page.

The vm\_cflush kernel service can only be called with addresses in the system (kernel) address space.

#### **Execution Environment**

The vm cflush kernel service can be called from both the interrupt and the process environment.

#### **Return Values**

The vm cflush kernel service has no return values.

### **Related Information**

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vm\_det Kernel Service

## Purpose

Unmaps and deallocates the region in the current address space that contains a given address.

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
void vm_det ( eaddr)
caddr_t eaddr;
```

#### **Parameter**

eaddr

Specifies the effective address in the current address space. The region containing this address is to be unmapped and deallocated.

### **Description**

The **vm** det kernel service unmaps the region containing the eaddr parameter and deallocates the region, adding it to the free list for the current address space.

The vm\_det kernel service assumes an address space model of fixed-size virtual memory objects and address space regions.

Attention: If the region is not mapped, or a system region is referenced, the system will halt.

#### **Execution Environment**

The vm\_det kernel service can be called from either the process or interrupt environment.

#### Related Information

The vm\_att kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vm\_flushp Kernel Service

### **Purpose**

Flushes the specified range of pages.

## **Syntax**

```
#include <svs/tvpes.h>
#include <sys/errno.h>#include <sys/vmuser.h>
int vm flushp ( sid, pfirst, npages)
vmid t sid;
vpn t pfirst;
```

#### **Parameters**

vpn\_t npages;

sid Identifies the base segment.

pfirst The first page number within the range.

npages The number of pages to flush starting from the *pfirst* value. All pages must be in the same segment.

## **Description**

The vm\_flushp kernel service routine initiates page-out for the specified page range in the virtual memory object. I/O is initiated for the modified pages only. If page-out is initiated, or the pages are currently undergoing page I/O, then they are flagged to have their page frames released upon completion. If the pages are not modified, their page frames are immediately released.

The caller can wait for the completion of I/O initiated by this and prior calls by calling the vms iowait kernel service.

**Note:** The **vm flushp** subroutine is not supported for use on large pages.

#### **Execution Environment**

The vm\_flushp kernel service can be called from the process environment only.

This is intended for files, and might not be called for working storage segments.

### **Return Values**

Indicates the completion of the flush operation.

**EINVAL** 

Indicates one of the following errors:

- *pfirst* < 0.
- npages < 0.
- · Page interval not in one segment.
- · Invalid sid parameter.
- · Invalid segment type.

#### **Related Information**

The vm\_write, vm\_writep, vm\_invalidatep and vms\_iowait kernel services.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm\_galloc Kernel Service

## **Purpose**

Allocates a region of global memory in the 64-bit kernel.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm_galloc (int type, vmsize t size, ulong * eaddr)
```

## **Description**

The **vm galloc** kernel service allocates memory from the kernel global memory pool on the 64-bit kernel. The allocation size is rounded up to the nearest 4K boundary. The default page protection key for global memory segments is 00 unless overridden with the V\_UREAD flag.

The type field may have the following values, which may be combined:

V_WORKING	Required. Creates a working storage segment.
V_SYSTEM	The new allocation is a global system area that does not belong to any application. Storage reference errors to this area will result in system crashes.
V_UREAD	Overrides the default page protection of 00 and creates the new region with a default page protection of 01.
V_NOEXEC	Pages in the region will have no-execute protection by default. Only supported on POWER4 <sup>™</sup> and later hardware.

The vm galloc kernel service is intended for subsystems that have large data structures for which xmalloc is not the best choice for management. The kernel xmalloc heap itself does reside in global memory.

#### **Parameters**

type Flags that may be specified to control the allocation. size Specifies the size, in bytes, of the desired allocation. eaddr Pointer to where vm\_galloc will return the start address of the allocated storage.

#### **Execution Environment**

The vm\_galloc kernel service can be called from the process environment only.

#### Return Values

Successful completion. A new region was allocated, and

its start address is returned at the address specified by

the eaddr parameter.

**EINVAL** Invalid size or type specified.

Not enough space in the galloc heap to perform the **ENOSPC** 

allocation.

**ENOMEM** Insufficient resources available to satisfy the request.

#### **Related Information**

The vm gfree kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vm\_gfree Kernel Service

## **Purpose**

Frees a region of global memory in the kernel previously allocated with the **vm** galloc kernel service.

## **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm_gfree (ulong eaddr, vmsize t size)
```

## **Description**

The vm\_gfree kernel service frees up a global memory region previously allocated with the vm\_galloc kernel service. The start address and size must exactly match what was previously allocated by the vm\_galloc kernel service. It is not valid to free part of a previously allocated region in the vm\_galloc area.

Any I/O to or from the region being freed up must be guiesced before calling the vm gfree kernel service.

#### **Parameters**

eaddr Start address of the region to free. Size in bytes of the region to free. size

#### **Execution Environment**

The **vm gfree** kernel service can be called from the process environment only.

#### **Return Values**

Successful completion. The region was freed.

**EINVAL** Invalid size or start address specified. This could mean that the region is out of range of the vm\_galloc heap,

was not previously allocated with vm\_galloc, or does not exactly match a previous allocation from vm\_galloc.

### **Related Information**

The vm galloc kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm quatt Kernel Service

### Purpose

Attaches an area of global kernel memory to the current process's address space.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm guatt (kaddr, size, key, flags, uaddr)
void * kaddr;
vmsize t size;
vmkey t key;
long flags;
void ** uaddr;
```

#### **Parameters**

kaddr Kernel address to be attached (returned from vm\_galloc when the global memory was allocated).

Length of the region to be inserted into the process address space, in bytes. size Protection key that the process will use when accessing the attached region. key

Type of vm\_quatt operation; must be set to VU\_ANYWHERE. flags

uaddr Pointer to user space address where the region was attached by vm\_quatt. The location pointed to

by uaddr (\*uaddr) must be null when the vm\_guatt call is made.

# **Description**

vm\_guatt is a kernel service used to attach a region of global kernel memory that was allocated with vm galloc to a process's address space. If the call is successful, the address in the process address space where the memory was attached is returned in the location pointed to by uaddr.

key can be set to VM PRIV or VM UNPRIV. If it is set to VM PRIV, the process will be able to read and write the attached region. If it is set to VM UNPRIV, the process will not be able to write the region and will only be able to read it if the vm\_galloc of the region was done with the V\_UREAD flag on.

vm\_guatt attachments are not inherited across a process fork.

#### **Execution Environment**

The vm\_guatt kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation. **EINVAL** Indicates one of the following errors:

- flags or key is not set to a valid value, size is 0, or the value pointed to by uaddr is non-NULL.
- · Region indicated by kaddr and size does not lie within a region previously allocated by vm\_galloc.

### Implementation Specifics

The vm\_guatt kernel service is part of Base Operating System (BOS) Runtime.

#### Related Information

"vm\_galloc Kernel Service" on page 521, "vm\_gudet Kernel Service," Memory Kernel Services

### vm\_gudet Kernel Service

### **Purpose**

Removes a region attached with **vm guatt** from the current process's address space.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm gudet (kaddr, uaddr, size, flags)
void * kaddr;
void * uaddr;
vmsize t size;
long f\bar{l}ags;
```

#### **Parameters**

kaddr Kernel address attached by vm\_guatt.

uaddr Location in the process address space where the kernel region was attached.

size Length of the attached region, in bytes.

flags Type of vm\_gudet operation, must be VU\_ANYWHERE.

# **Description**

vm\_gudet is a kernel service that detaches a region of global kernel memory that was attached by vm\_guatt. This memory must still be allocated, detaching a region after it has been deallocated with vm\_gfree is an error. If the detach is successful, the global kernel memory region at kaddr will no longer be addressable at *uaddr* by the calling process.

#### **Execution Environment**

The vm\_gudet kernel service can be called from the process environment only.

#### **Return Values**

User address detached successfully. **EINVAL** Indicates one of the following errors:

- · Invalid flags.
- Region indicated by kaddr and size does not lie within a region allocated by vm\_galloc.

### Implementation Specifics

The vm\_gudet kernel service is part of Base Operating System (BOS) Runtime.

#### Related Information

### vm handle Kernel Service

### Purpose

Constructs a virtual memory handle for mapping a virtual memory object with a specified access level.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
vmhandle_t vm_handle ( vmid, key)
vmid t vmid;
int key;
```

#### **Parameters**

Specifies a virtual memory object identifier, as returned by the vms create kernel service. vmid

Specifies an access key. This parameter has a 1 value for limited access and a 0 value for unlimited access, key respectively.

# **Description**

The vm\_handle kernel service constructs a virtual memory handle for use by the vm\_att kernel service. The handle identifies the virtual memory object specified by the *vmid* parameter and contains the access key specified by the *key* parameter.

A virtual memory handle is used with the vm\_att kernel service to map a virtual memory object into the current address space.

The vm handle kernel service assumes an address space model of fixed-size virtual memory objects and address space regions.

#### **Execution Environment**

The vm\_handle kernel service can be called from the process environment only.

#### **Return Values**

The **vm\_handle** kernel service returns a virtual memory handle type.

#### **Related Information**

The vm att kernel service, vms create kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm invalidatep Kernel Service

### **Purpose**

Releases page frames in the specified range for a non-journaled persistent segment or client segment.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm_invalidatep ( sid, pfirst, npages)
vmid t sid;
vpn_t pfirst;
ulong npages;
```

#### **Parameters**

sid Identifies the base segment.

pfirst The first page number within the range.

npages The number of pages to invalidate starting from the *pfirst* value. All pages must be in the same segment.

# **Description**

The vm invalidatep kernel service routine discards any page frames associated with the virtual memory object in the specified page range.

If a page within the specified range is found in page-in or page-out state, then the thread is synchronously put to sleep until the page I/O completes. When the I/O is complete, any memory-resident page frame is then freed.

Note: The vm\_invalidatep subroutine is not supported for use on large pages.

#### **Execution Environment**

The vm\_invalidatep kernel service can be called from the process environment only.

This is intended for files, and might not be called for working storage segments.

#### **Return Values**

0 Indicates the completion of the invalidating operations.

#### EINVAL

Indicates one of the following errors:

- *pfirst* < 0.
- npages < 0.
- · Page interval not in one segment.
- · Invalid sid parameter.
- · Invalid segment type.

#### **Related Information**

The vm write, vm writep, vm flushp and vms iowait kernel services.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm ioaccessp Kernel Service

### **Purpose**

Initiates asynchronous page-in or page-out for the range of pages specified.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm_ioaccessp ( bsid, pfirst, npages, modifier)
vmid t bsid;
vpn t pfirst;
vpn_t npages;
uint modifier;
```

#### **Parameters**

bsid Identifies the base segment.

pfirst The first page number within the range.

npages The number of pages to access starting from the pfirst value. All pages must be in the same segment.

Flags passed in by the user. These flags are detailed below. modifier

# **Description**

The vm ioaccessp kernel service routine enables a client file system with a thread-level strategy routine to access the pages specified. This call is strictly advisory and might return without having done anything. If you want to actually move the data, call the vm uiomove kernel service. If you want to pre-page the target, then call the vm\_readp kernel service.

The flags passed in through the *modifier* parameter determine what type of action taken by the vm\_ioaccessp kernel service. For details of each flag's purpose, see the table below.

The flags carry certain restrictions. You cannot request both a make and a flush operation. Also, if the VM\_IOACCESSP\_WAITONLY flag is declared then you must specify at least one type of wait operation. Finally, you cannot request a make or a flush operation if the VM\_IOACCESSP\_WAITONLY flag is declared.

### **Flags**

Value	Name	Purpose
0x0001	VM_IOACCESSP_MAKE	Creates new pages in the page-in state in the specified range. Can only make up to 1MB of pages.
0x0002	VM_IOACCESSP_FLUSH	Flushes pages in the specified range.
0x0004	VM_IOACCESSP_PGINWAIT	If a page in the specified range is in page-in state, then block until page-in is complete.
8000x0	VM_IOACCESSP_PGOUTWAIT	If a page in the specified range is in page-out state, then block until page-out is complete.
0x0010	VM_IOACCESSP_WAITONLY	Returns once the specified wait is complete. The VM_IOACCESSP_PGINWAIT flag and the VM_IOACCESSP_PGOUTWAIT flag must also be specified.

#### **Execution Environment**

The **vm** ioaccessp kernel service can be called from the process environment only.

### **Return Values**

Indicates the completion of the I/O access operations.

**EINVAL** Indicates one of the following errors:

- *pfirst* < 0.
- npages < 0.</li>
- · Page interval not in one segment.
- Invalid sid parameter.
- Page make requests > 1MB.
- · Not a client file system.
- · Unsupported flag used.
- Both the VM\_IOACCESSP\_MAKE and the VM\_IOACCESSP\_FLUSH flags are set.
- . The VM IOACCESSP WAITONLY flag is set and the VM IOACCESSP PGINWAIT flag or the VM\_IOACCESSP\_PGOUTWAIT flag is not set.
- The VM\_IOACCESSP\_WAITONLY flag and the VM\_IOACCESSP\_MAKE flag or the VM\_IOACCESSP\_FLUSH flag are set.

#### **Related Information**

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vm\_makep Kernel Service

# **Purpose**

Makes a page in client storage.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm makep ( vmid, pno)
vmid_t vmid;
int pno;
```

#### **Parameters**

vmid Specifies the ID of the virtual memory object.

Specifies the page number in the virtual memory object. pno

### **Description**

The vm makep kernel service makes the page specified by the pno parameter addressable in the virtual memory object without requiring a page-in operation. The vm\_makep kernel service is restricted to client storage.

The page is not initialized to any particular value. It is assumed that the page is completely overwritten. If the page is already in memory, a value of 0, indicating a successful operation, is returned.

#### **Execution Environment**

The **vm makep** kernel service can be called from the process environment only.

### **Return Values**

Indicates a successful operation.

EINVAL Indicates a virtual memory object type or page number that is not valid.

**EFBIG** Indicates that the page number exceeds the file-size limit.

#### **Related Information**

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vm\_mem\_policy System Call

# **Purpose**

Allows callers to get or set their applications' default memory placement policies.

# Library

Standard C Library (libc.a)

# **Syntax**

#include <sys/rset.h>

#include <sys/vminfo.h>

int vm mem policy(int cmd, int \*early Iru, int \*policies, int num policies)

# Description

The vm\_mem\_policy system call allows callers to get or set their applications' default memory placement policies for different types of memory.

Following are the different types of placement policies:

P\_FIRST\_TOUCH Places the memory at the MCM where the application first referenced it. This is also achieved by setting the MEMORY\_AFFINITY environment variable to MCM and benefit the applications with an identified home MCM to run on.

P\_BALANCED Uses the stripe memory in the application across all the system's MCMs. This benefits

applications that do not identify a home MCM to run on, or on global memory objects that is

accessed by many applications.

P\_DEFAULT Accepts the system's default policy for memory placement, which can be either the first touch or

balanced policy, depending on the circumstances and the type of memory.

The vm\_mem\_policy system call allows the caller to get or set the early\_Iru flag, which triggers the system to look for stealable pages immediately after a P FIRST TOUCH driven scan for local memory (the memory on the same **MCM** the application is running on) does not find any available pages.

The parameters policies, and num\_policies allow a caller to fine control over the default memory placement policies of different types of memory. The policy settings take effect on any new memory page the application creates after having called this function. The existing memory pages of the application retains their existing memory placement.

#### **Parameters**

policies

cmd A command that is either VM\_SET\_POLICY or VM\_GET\_POLICY. The VM\_GET\_POLICY

> command copies the current policy setting into the buffers supplied by the caller, and does not change any of the process policies. The VM SET POLICY command reads input from

the supplied buffers and changes the process policies accordingly.

early\_Iru A pointer to an integer that indicates the state of the early Iru setting for first touch policy. Enabling early\_Iru causes memory to be paged out in order to fulfill a first-touch request for memory placement.

The possible values for early Iru are:

0 turn off early\_Iru.

turn on early\_Iru.

do not modify early\_lru setting for VM\_SET\_POLICY.

A pointer to an array of policies for distinct types of memory. Each array element contains one of the policy types. The array element contains -1 to leave the policy unchanged for the corresponding memory type. The array must be declared with a length of

VM\_NUM\_POLICIES. The list that follows enumerates the memory types whose policies can be changed in the form of constants. Enter the constant that is an array index into the policies array for the corresponding memory type.

#### VM POLICY TEXT

policy for executable program text

#### VM\_POLICY\_STACK

policy for program stack

#### VM POLICY DATA

policy for program heap and private mmap data

#### VM\_POLICY\_SHM\_NAMED

policy for shared memory obtained via shm\_open() or shmget() with a key

#### VM\_POLICY\_SHM\_ANON

policy for anonymous mmap memory, or shared memory obtained via shmget() with IPC\_PRIVATE key

#### VM\_POLICY\_MAPPED\_FILE

policy for files mapped into the address space via shmat() or mmap()

#### VM\_POLICY\_UNMAPPED\_FILE

policy for open files that are not mapped

Number of elements in the policies array. This value must be set to VM\_NUM\_POLICIES. num\_policies

### vm\_mount Kernel Service

### **Purpose**

Adds a file system to the paging device table.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>

int vm_mount ( type, ptr, nbufstr)
int type;
int (*ptr)();
int nbufstr;
```

#### **Parameters**

type Specifies the type of device. The type parameter must have a value of **D\_REMOTE**.

ptr Points to the file system's strategy routine.nbufstr Specifies the number of buf structures to use.

### **Description**

The **vm\_mount** kernel service allocates an entry in the paging device table for the file system. This service also allocates the number of **buf** structures specified by the *nbufstr* parameter for the calls to the strategy routine.

#### **Execution Environment**

The vm\_mount kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

**ENOMEM** Indicates that there is no memory for the **buf** structures.

**EINVAL** Indicates that the file system strategy pointer is already in the paging device table.

### **Related Information**

The vm\_umount kernel service, the vm\_setdevid kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm\_mounte Kernel Service

# **Purpose**

Adds a file system with a thread-level strategy routine to the paging device table.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

int vm\_mounte ( in\_dtype, in\_devid, in\_thrinfop) int in dtype; dev\_t in\_devid; struct thrpginfo \* in\_thrinfop;

#### **Parameters**

in\_dtype Specifies the type of device. Supported device types are D REMOTE, D LOGDEV, D SERVER,

**D\_LOCALCLIENT**. Other optional flags are detailed below.

If the type is **D\_LOGDEV**, specifies a dev\_t object of the block device. If the type is **D\_REMOTE** in\_devid

or **D\_SERVER**, specifies a pointer to a strategy routine.

in\_thrinfop Pointer to a thrpginfo structure.

### **Description**

The vm\_mounte kernel service allocates an entry in the paging device table for the device specified. The vm mounte kernel service can also mount a client file system with a thread-level strategy routine. This is done by passing in the **D\_THRPGIO** and the **D\_ENHANCEDIO** flags.

### **Flags**

Name **Purpose** 

**D ENHANCEDIO** Indicates an enhanced I/O-aware file system.

**D PREXLATE** Enables pre-translation as the default for all but remote file systems.

**D THRPGIO** Indicates a thread-level strategy routine.

#### **Execution Environment**

The **vm\_mounte** kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

**ENOMEM** Indicates that there is no memory for the buf or the thrpginfo structure. **EINVAL** Indicates one of the following errors:

> The file system strategy pointer is already in the paging device table, or in case of D SERVER, a server is already defined.

- The in\_dtype parameter is set to the **D\_PAGING** or the **D\_FILESYSTEM** value.
- · The thrpginfo structure has not been initialized correctly.
- The D THRPGIO flag has been set without the D ENHANCEDIO flag.

#### **Related Information**

The vm umount kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm\_move Kernel Service

# **Purpose**

Moves data between a virtual memory object and a buffer specified in the uio structure.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
#include <sys/uio.h>
int vm_move (vmid, offset, limit, rw, uio)
vmid t vmid;
caddr_t offset;
int limit;
enum uio rw rw;
struct uio * uio;
```

#### **Parameters**

vmid Specifies the virtual memory object ID.

offset Specifies the offset in the virtual memory object.

limit Indicates the limit on the transfer length. If this parameter is negative or 0, no bytes are transferred. Specifies a read/write flag that gives the direction of the move. The possible values for this parameter rw

(UIO\_READ, UIO\_WRITE) are defined in the /usr/include/sys/uio.h file.

Points to the uio structure. uio

### **Description**

The vm\_move kernel service moves data between a virtual memory object and the buffer specified in a uio structure.

This service determines the virtual addressing required for the data movement according to the offset in the object.

The vm move kernel service is similar to the uiomove kernel service, but the address for the trusted buffer is specified by the vmid and offset parameters instead of as a caddr\_t address. The offset size is also limited to the size of a caddr t address since virtual memory objects must be smaller than this size.

**Note:** The **vm move** kernel service does not support use of cross-memory descriptors.

I/O errors for paging space and a lack of paging space are reported as signals.

#### **Execution Environment**

The **vm** move kernel service can be called from the process environment only.

#### **Return Values**

0 Indicates a successful operation.

**EFAULT** Indicates a bad address. **ENOMEM** Indicates insufficient memory. **ENOSPC** Indicates insufficient disk space.

EIO Indicates an I/O error.

Other file system-specific errno global variables are returned by the virtual file system involved in the move function.

#### **Related Information**

The **uiomove** kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm mvc Kernel Service

### **Purpose**

Reads or writes partial pages of files.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm_mvc ( in_sid, in_pno, in_pgoffs, in_count, in_cmd, in_xmemdp, in_ptr)
vmid_t in_sid;
vpn_t in_pno;
int in paoffs:
int in_count;
int in_cmd;
struct xmem * in_xmemdp;
void * in_ptr;
```

#### **Parameters**

in sid The primary memory object, m1.

in\_pno The m1 pno object. If it is a read operation, this parameter refers to the source. If not, it refers to a

target.

in\_pgoffs The byte offset in the pno object.

in count The number of bytes to zero or copy in memory.

The reason for the function call. The possible values could be Zero, Zero(protect), read, or write. in\_cmd

in\_xmemdp The xmem descriptor for the second memory object, m2.

in\_ptr The byte offset in the xmem object.

# **Description**

The vm mvc kernel service is meant to be used by client file systems doing read or write operations to partial pages of files, where the file is denoted by the m1 object and the read or write buffer by the m2 object. Such cases arise on EOF handling, fragments, compression, and holes among other situations.

Given two memory object, m1 and m2, the vm\_mvc kernel service allows you to do one of the following operations:

- Zero out bytes on the m1 object (VM MVC ZERO).
- Zero out and protect the m1 object (VM MVC PROTZERO).
- Copy bytes from the m1 object to the m2 object (VM MVC READ).
- Copy bytes from the m2 object to the m1 object (VM MVC WRITE).

The first memory object, m1, is characterized by a *sid* parameter and a *pno* parameter. The second memory object, m2, is characterized by an xmem descriptor and a pointer for an offset. The second memory object is a user or kernel buffer.

**Note:** The second memory object must be pinned.

### **Flags**

in\_cmd **Purpose** 

VM\_MVC\_ZERO Zeros out the bytes on the m1 object. VM\_MVC\_READ Copies bytes from the m1 object to the m2 object. VM\_MVC\_WRITE Copies bytes from the m2 object to the m1 object.

VM\_MVC\_PROTZERO Zeros out and protects the m1 object.

#### **Execution Environment**

The **vm mvc** kernel service can be called from the process environment only.

#### **Return Values**

Indicates that the I/O access operations completed successfully. **ENOENT** Indicates that the (sid, pno) set was not mapped to a real frame.

EINVAL Indicates one of the following errors:

- · The m1 object crosses page boundary.
- The in\_cmd parameter does not contain a valid command.

#### **Related Information**

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm\_pattr System Call and kvm\_pattr Kernel Service

### Purpose

Queries or modifies virtual memory attributes.

# Library

Standard C Library (libc.a)

# **Syntax**

```
#include <sys/vmpattr.h>
int vm_pattr (
long cmd,
pid t pid,
void * attr.
size_t attr_size );
int kvm_pattr (
long cmd,
pid t pid,
void * attr,
size_t attr size );
```

# **Description**

The vm\_pattr system call queries or modifies memory attributes of the calling process's address space or that of another user process.

The **kvm** pattr kernel service provides the same function to kernel subsystems (kernel extensions, kernel processes and so on) except that it cannot modify another kernel process' memory attributes.

#### **Parameters**

cmd The following commands can be passed in:

#### VM\_PA\_SET\_PSIZE or VM\_PA\_GET\_PSIZE

These commands set or retrieve the page size used for a specified memory range.

#### VM\_PA\_GET\_RMUSAGE

This command retrieves the amount of the real memory in bytes being used for a specified memory range.

#### VM\_PA\_SET\_PSPA or VM\_PA\_GET\_PSPA

These commands set or retrieve the page size promotion aggressiveness factor for a specified memory range.

#### VM\_PA\_GET\_PSPA\_ALIGN

This command retrieves the minimum memory alignment necessary for memory ranges specified to the vm pattr kernel service when using the VM PA SET PSPA command.

#### VM\_PA\_CHECK\_PSIZE

This command reports if a specified page size can be used for a memory range. Specifies the ID of the process whose memory attributes are to be gueried or modified. A value of -1 specifies the calling process. The root user can specify any process ID, but other users can only specify processes they own (that is, the target process's user ID must match the calling process's user ID).

The vm\_pattr system call is only supported on user processes while the kvm\_pattr kernel service can target user processes or its own kernel process (for example, pid = -1).

pid

attr A pointer to a structure describing the effective address range for the memory being queried or modified and additional data depending on the command.

The range is specified through the following **vm\_pa\_range** structure:

The range specified must be in the target process's address space and must correspond to one of these process areas:

- · Main program data (initialized, bss, or heap).
- Shared library data or private module load area data.
- · Privately loaded text.
- · Initial thread stack area.
- Anonymous shared memory (System V shared memory, extended System V shared through EXTSHM, and POSIX real-time shared memory). The target process must have write access to the memory in order to change the attributes of the shared memory range.
- · Anonymous mmap memory.

If the memory range specified includes shared memory or mmap memory, the calling process must have write access to the memory according to the shared memory descriptor or mapping attributes in order to change the attributes of the range. The range can have additional restrictions based on the following commands.

The structure specified through the *attr* parameter must be a pointer to one of the following structures:

#### VM PA SET PSIZE or VM PA GET PSIZE

These commands take a pointer to the following structure:

For the VM\_PA\_SET\_PSIZE command, the *pa\_psize* parameter is the page size (in bytes) to use for the given range. This is an advisory setting that might or might not be used at the operating system's discretion. This must be a valid page size between the minimum and maximum page sizes of all segments in the range. Additionally, the range must start and end on a multiple of the specified page size. If an error occurs during the processing of this command, any successfully altered page size settings can remain set.

For the VM\_PA\_GET\_PSIZE command, the page size (in bytes) backing the specified memory range is returned in the *pa\_psize* parameter. The range must start and end on a multiple of the smallest page size supported as reported by the **sysconf(\_SC\_PAGE\_SIZE)** subroutine. If the range is using multiple page sizes, the smallest page size in the range is reported. Unlike the VM\_PAGE\_INFO command of the vmgetinfo subroutine that reports the segment's base page size, the page size reported by the VM\_PA\_GET\_PSIZE command is the actual page size being used at the time the vm\_pattr system call was called. The page size reported is transient because the operating system can change the backing page size at any time. Therefore, the page size reported must be for informational purposes only.

attr (continued)

#### VM\_PA\_GET\_RMUSAGE

This command takes a pointer to the following structure:

```
struct vm_pa_rmusage
                  struct vm pa range pa range;
                  size64_t pa_rbytes;
            };
```

This command reports the amount of real memory (in bytes) used for the given range in the pa\_rbytes field. This can help an application decide whether it needs to use a large page size for a specific range based on how much real memory the range is using. For example, if a 64KB range is only using 4KB of real memory, then it does not make sense to try to use a 64KB page size for that range. But if it is using all 64KB or some large percentage of it, then the application might decide to use a 64KB page size. The range specified for this command has no alignment requirements for this command, and the command includes only those bytes in the range that are using real memory.

#### VM\_PA\_SET\_PSPA or VM\_PA\_GET\_PSPA

These commands take a pointer to the following structure:

```
struct vm pa pspa
                    struct vm pa range pa range;
                    int pa pspa;
             };
```

The VM\_PA\_SET\_PSPA command can set the page size promotion aggressiveness for the specified range. The pa\_pspa setting is in the same units as the vmm\_default\_pspa vmo tunable. This setting is the inverse of the real memory occupancy threshold needed to promote to a large page size and ranges from -1 to 100. The value of -1 indicates that no page promotion can occur regardless of the occupancy of the memory range. A value of 0 indicates a page size promotion can only be done when the memory range is fully occupied. A value of 100 indicates a page promotion must be done at the first reference to the memory range.

This setting is only supported at a segment granularity, so the range must start and end on a segment boundary. The alignment requirement for the range can be found using the VM PA GET PSPA ALIGN command with the vm pattr system call.

If an error occurs during the processing of the VM PA SET PSPA command, the vm pattr system call can return after altering the page size promotion thresholds for part of the specified

The VM\_PA\_GET\_PSPA command retrieves the page size promotion aggressiveness factor for the specified range. If the range spans multiple segments consisting of different page promotion thresholds, the pa pspa field is updated with the least aggressive PSPA setting (the smallest PSPA setting across all of the segments).

The PSPA commands are not supported on mmap or EXTSHM memory ranges.

attr (continued)

#### VM\_PA\_GET\_PSPA\_ALIGN

This command takes a pointer to the following structure:

The VM\_PA\_GET\_PSPA\_ALIGN command returns the minimum memory alignment requirements of a memory range for the VM\_PA\_SET\_PSPA command in the pa\_pspa\_align field based on what segments are contained in the specified memory range. If a memory range spans segments with different alignment requirements, this command returns the largest of the alignment requirements.

The alignment requirements for the VM\_PA\_SET\_PSPA command are as follows:

Process's Memory Area	<b>Minimum Alignment</b>
Main process data	256MB
Process stack	256MB
Shared Library data	256MB
Privately loaded module data	256MB
Privately loaded module text	256MB
POSIX Real-Time Shared Memory	256MB
Anonymous MMAP	256MB
Anonymous Extended System V Shared memory	256MB
Anonymous System V Shared memory with page sizes <= 256MB	256MB
Anonymous System V shared memory backed with 16GB page size	1TB

#### VM PA CHECK PSIZE

This command takes a pointer to the following structure:

The VM\_PA\_CHECK\_PSIZE command determines if a specific page size is allowed by the VM\_PA\_SET\_PSIZE command for a specified memory range. The VM\_PA\_CHECK\_PSIZE command can be used when the application wants more detailed information about why a VM\_PA\_SET\_PSIZE operation fails, or to check if a VM\_PA\_SET\_PSIZE operation will successfully modify the page size for the range specified.

This command must be used on a memory range that spans a single page and is aligned to the page size specified by the *pa\_psize* parameter. If the page size can be used for that range, the *pa\_reason* parameter is set to 0. Otherwise, it is set to a reason code defined in the **vmpattr.h** header file.

VMPATTR_SET_PSIZE_VALID	The specified page size can be used for
	the specified range.
VMPATTR_INVALID_MPSS_PSIZE	The specified page size is not supported in
	mixed page size segments.
VMPATTR_NON_MPSS_SEGMENT	The address range specified is from a
	segment that does not support mixed page
	sizes.

VMPATTR\_NON\_MPSS\_PAGE The size of the target page cannot be

> modified. For example, this reason code can be returned when trying to set an address range to a 64K page size if a portion of the range has page protection settings that do not match the rest of the

range.

VMPATTR\_RDONLY\_MEM The target range cannot be modified

because the caller does not have write

access to the memory specified.

The attr\_size parameter must be the size of the structure needed (or greater) for the specified attr\_size

command.

#### **Return Values**

When successful, these commands return 0. Otherwise, they return -1 and set the errno global variable to indicate the error.

#### **Error Codes**

**EPERM** The calling process does not have the appropriate privilege to perform the

requested operation.

**ESRCH** The target process does not exist or is not in a valid state.

> The range specified contains a hole. A hole is any part of the target process's address space that is not backed by a virtual memory segment or is outside

> > of the valid range of the virtual memory segment specified. Any of the following situations can cause the **ENOTSUP** error:

• The target process is a kernel process other than the calling process.

- The command specified was the VM PA SET PSIZE command and the
- page size specified is not supported for multiple page size segments. • The command specified was either the VM\_PA\_GET\_PSPA or the VM\_PA\_SET\_PSPA command and the specified memory range includes

mmap or EXTSHM segment(s).

Any of the following situations can cause the EINVAL error:

- The attr\_size parameter specified is less than the size of the structure needed for this command.
- The range specified is outside the process's address space (for example, global kernel memory).
- The command specified was the VM\_PA\_SET\_PSIZE command and the page size specified was not a valid page size supported by the system.
- The command specified was the VM PA SET PSPA command and the address range specified was not aligned to the segment size backing the range.
- The command specified was the VM\_PA\_SET\_PSPA command and the page promotion aggressiveness factor specified was not valid.
- The command specified was the VM PA CHECK PSIZE command and the address range specified was not aligned to the page size specified.

#### **Related Information**

Dynamic variable page size support in AIX Version 7.1 Performance management.

**ENOMEM** 

**ENOTSUP** 

**EINVAL** 

### vm\_protect\_kkey Kernel Service

### **Purpose**

Sets kernel-key on a kernel address range.

### **Syntax**

```
#include <sys/types.h>
#include <sys/skeys.h>
#include <sys/vmuser.h>

kerrno_t vm_protect_kkey (eaddr, nbytes, kkey, flags)
void * eaddr;
size_t nbytes;
kkey_t kkey;
unsigned long flags;
```

#### **Parameters**

eaddr Starting address to protect.nbytes Number of bytes to protect.

*kkey* Kernel-key value to set on memory.

flags Defined flag value is:

 VMPK\_NO\_CHECK\_AUTHORITY – This flag indicates that extended authority checking will not be performed.

# **Description**

The **vm\_protect\_kkey()** kernel service is used to alter the kernel-key associated with a virtual memory range. If set, any code that references the memory needs to include the kernel-key in their active keyset. The kernel-key is set for all pages in the effective address range specified by *eaddr* to *eaddr* + *nbytes* - 1. If the address range does not specify a page-aligned area consisting of an integral number of full pages, an error will be returned.

By default, an authority check is performed when altering storage-keys. This check requires that the **vm\_protect\_kkey()** caller has write access to the pages' current kernel-key(s). This authority checking can be overridden by setting the **VMPK\_NO\_CHECK\_AUTHORITY** value, but this is not recommended since the check can protect against some programming errors.

#### **Execution Environment**

The vm\_protect\_kkey kernel service can be called from the process environment only.

#### **Return Values**

0 Successful.

**EINVAL\_VM\_PROTECT\_KKEY** Invalid parameter or execution environment.

EINVAL\_VM\_PROTECT\_KKEY\_PPAGE Request includes a partial page.

**EFAULT\_VM\_PROTECT\_KKEY** Invalid address range.

**EPERM\_VM\_PROTECT\_KKEY** Insufficient authority to perform the operation.

If the **vm\_protect\_kkey()** kernel service is unsuccessful because of a condition other than that specified by the **EINVAL\_VM\_PROTECT\_KKEY** error code, the kernel-key for some pages in the (*eaddr*, *eaddr* + *nbytes* - 1) range might have been changed.

#### **Related Information**

The vm\_setseg\_kkey kernel service.

### vm\_protectp Kernel Service

### **Purpose**

Sets the page protection key for a page range.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm_protectp ( vmid, pfirst, npages, key)
vmid_t vmid;
int pfirst;
int npages;
int key;
```

### **Description**

The vm\_protectp kernel service is called to set the storage protect key for a given page range. The key parameter specifies the value to which the page protection key is set. The protection key is set for all pages touched by the specified page range that are resident in memory. The vm\_protectp kernel service applies only to client storage.

If a page is not in memory, no state information is saved from a particular call to the vm\_protectp service. If the page is later paged-in, it receives the default page protection key.

**Note:** The **vm protectp** subroutine is not supported for use on large pages.

#### **Parameters**

vmid	Specifies the identifier for the virtual memory object for which the page protection key is to be set.
pfirst	Specifies the first page number in the designated page range.
npages	Specifies the number of pages in the designated page range.
kev	Specifies the value to be used in setting the page protection key for the designated page range.

#### **Execution Environment**

The vm\_protectp kernel service can be called from the process environment only.

#### **Return Values**

0 Indicates a successful operation. **EINVAL** 

Indicates one of the following errors:

- · Invalid virtual memory object ID.
- The starting page in the designated page range is negative.
- · The number of pages in the page range is negative.
- The designated page range exceeds the size of virtual memory object.
- · The target page range does not exist.
- One or more large pages lie in the target page range.

#### **Related Information**

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm\_qmodify Kernel Service

### **Purpose**

Determines whether a mapped file has been changed.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm qmodify ( vmid)
vmid t vmid;
```

#### **Parameter**

vmid Specifies the ID of the virtual memory object to check.

### **Description**

The vm qmodify kernel service performs two tests to determine if a mapped file has been changed:

- The vm qmodify kernel service first checks the virtual memory object modified bit, which is set whenever a page is written out.
- If the modified bit is 0, the list of page frames holding pages for this virtual memory object are examined to see if any page frame has been modified.

If both tests are false, the vm\_qmodify kernel service returns a value of False. Otherwise, this service returns a value of True.

If the virtual memory object modified bit was set, it is reset to 0. The page frame modified bits are not changed.

#### **Execution Environment**

The vm\_qmodify kernel service can be called from the process environment only.

#### **Return Values**

**FALSE** Indicates that the virtual memory object has not been modified. TRUE Indicates that the virtual memory object has been modified.

#### **Related Information**

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm\_qpages Kernel Service

### **Purpose**

Returns the number of in-memory page frames associated with the virtual memory object.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
vpn_t vm_qpages ( sid)
vmid t sid;
```

#### **Parameters**

sid Identifies the base segment.

### **Description**

The vm\_qpages kernel service routine returns the number of page frames associated with the virtual memory object with the sid parameter specified.

#### **Execution Environment**

The vm qpages kernel service can be called from the process environment only.

This function can be run for persistent, client, and working storage segments.

#### **Return Values**

npages The number of page frames. Indicates an invalid sid parameter. -1

#### **Related Information**

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vm\_readp Kernel Service

# **Purpose**

Initiates asynchronous page-in for the range of pages specified.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm_readp ( sid, pfirst, npages, flags)
vmid t sid;
vpn_t pfirst;
vpn t npages;
int flags;
```

#### **Parameters**

sid Identifies the base segment.

pfirst The first page number within the range.

npages The number of pages to read starting from the *pfirst* value. All pages must be in the same segment.

flags Flags used by the function.

### **Description**

The vm\_readp kernel service routine begins the process of reading a page. This call is strictly advisory and might return without having done anything.

The only flag passed in through the flag parameter, VM\_IOWAIT, tells the vm\_readp kernel service to wait for any page I/O in the range to complete before initiating the read operation. This flag is optional.

#### **Execution Environment**

The **vm** readp kernel service can be called from the process environment only.

#### **Return Values**

Indicates that the I/O access operations completed successfully.

EINVAL Indicates one of the following errors:

- *pfirst* < 0.
- npages < 0.
- · Page interval > Maximum file size.
- The *sid* parameter is not valid.
- · Not a file or persistent storage segment.

#### **Related Information**

The **vm writep** kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm release Kernel Service

### **Purpose**

Releases virtual memory resources for the specified address range.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm release ( vaddr, nbytes)
caddr t vaddr;
int nbytes;
```

### **Description**

The vm\_release kernel service releases pages that intersect the specified address range from the vaddr parameter to the vaddr parameter plus the number of bytes specified by the nbytes parameter. The value in the nbytes parameter must be nonnegative and the caller must have write access to the pages specified by the address range.

Each page that intersects the byte range is logically reset to 0, and any page frame is discarded. A page frame in I/O state is marked for discard at I/O completion. That is, the page frame is placed on the free list when the I/O operation completes.

Note: All of the pages to be released must be in the same virtual memory object.

**Note:** The **vm\_release** subroutine is not supported for use on large pages.

#### **Parameters**

vaddr Specifies the address of the first byte in the address range to be released.

Specifies the number of bytes to be released. nbytes

#### **Execution Environment**

The vm\_release kernel service can be called from the process environment only.

#### **Return Values**

EACCES EINVAL

Indicates successful completion.

Indicates that the caller does not have write access to the specified pages.

- Indicates one of the following errors: · The specified region is not mapped.
- The specified region is an I/O region.
- The length specified in the *nbytes* parameter is negative.
- · The specified address range crosses a virtual memory object boundary.
- · One or more large pages lie in the target page range.

#### **Related Information**

The vm\_releasep kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vm\_releasep Kernel Service

# **Purpose**

Releases virtual memory resources for the specified page range.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/vmuser.h>

```
int vm_releasep ( vmid, pfirst, npages)
vmid t vmid;
int pfirst;
int npages;
```

### Description

The vm\_releasep kernel service releases pages for the specified page range in the virtual memory object. The values in the *pfirst* and *npages* parameters must be nonnegative.

Each page of the virtual memory object that intersects the page range (pfirst, pfirst + npages -1) is logically reset to 0, and any page frame is discarded. A page frame in the I/O state is marked for discard at I/O completion.

For working storage, paging-space disk blocks are freed and the storage-protect key is reset to the default

Note: All of the pages to be released must be in the same virtual memory object.

**Note:** The **vm\_releasep** subroutine is not supported for use on large pages.

#### **Parameters**

vmid Specifies the virtual memory object identifier.

Specifies the first page number in the specified page range. pfirst Specifies the number of pages in the specified page range. npages

### **Execution Environment**

The vm\_releasep kernel service can be called from the process environment only.

#### Return Values

Indicates a successful operation.

**EINVAL** 

Indicates one of the following errors:

- · An invalid virtual memory object ID.
- · The starting page is negative.
- · Number of pages is negative.
- · Page range crosses a virtual memory object boundary.
- · One or more large pages lie in the target page range.

#### **Related Information**

The **vm release** kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vm\_segmap Kernel Service

# Purpose

Creates the segments associated with a range of bytes in a file and attaches them to the kernel's address space.

### **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm_segmap ( basesid, pfirst, flags, basepp)
vmid_t basesid;
vpn t pfirst;
uint flags;
caddr t * basepp;
```

#### **Parameters**

basesid Identifies the base segment.

The first page number within the range. The pfirst parameter is non-negative. pfirst

flags Optional flags passed in by the user. . The offset of the object to be attached. basepp

### **Description**

The vm\_segmap kernel service routine creates segments associated with a range of bytes in a file. Afterwards, it uses the vm\_att kernel service to map the specified virtual memory object to a region in the virtual address space and returns the effective address of that object in the basepp parameter.

#### **Execution Environment**

The **vm** segmap kernel service can be called from either the process or interrupt environment.

#### **Return Values**

caddr\_t The effective address of the attached object.

**EINVAL** Indicates one of the following errors:

• *pfirst* < 0.

· Invalid sid parameter.

**EFBIG** Indicates the range of values is too large to create.

### **Related Information**

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vm\_setdevid Kernel Service

# **Purpose**

Modifies the paging device table entry for a virtual memory object.

# **Syntax**

```
#include <sys/types.h>
#include <sys/kerrno.h>
#include <sys/vmuser.h>
kerrno t vm setdevid ( vmid, type, ptr, flags)
vmid_t vmid;
```

```
int type;
int (*ptr)();
unsigned long flags;
```

#### **Parameters**

vmid Specifies the identifier for the virtual memory object for which the paging device table entry is to be set.

Specifies the type of device. The *type* parameter must have a value of D\_REMOTE. type

Points to the strategy routine of the file system. ptr Reserved. You must set the *flags* parameter to zero. flags

### **Description**

The vm setdevid kernel service binds the paging device table entry associated with the file system strategy routine ptr, to the virtual memory object vmid. The paging device table entry must have already been mounted as type D REMOTE through a prior vm mount kernel service call.

After the file system has called the vm setdevid kernel service on a given virtual memory object, subsequent paging I/O will be performed to or from the newly specified paging device table. Any outstanding I/O's to the paging device table formerly associated with the virtual memory object, remain queued, and will complete asynchronously. After they complete, subsequent paging I/O to those file pages will be performed to or from the newly specified paging device table.

The paging device table entry currently associated with the *vmid* object, on input to this call, must be valid and of type D REMOTE. Any flags specified when the vm mount kernel service gets called must match exactly any flags specified when the vm\_mount kernel service gets called for the new paging device table entry.

#### **Execution Environment**

The vm setdevid kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

EINVAL\_VM\_SETDEVID1 Indicates that the *vmid* value is not a client segment, or the input type does not

have the value of D\_REMOTE.

ENODEV\_VM\_SETDEVID2 Indicates that a file system with the strategy routine designated by the ptr

parameter is not in the paging device table.

EINVAL\_VM\_SETDEVID3 Indicates that the new paging device table entry is not D\_REMOTE or is not valid. EINVAL\_VM\_SETDEVID4

Indicates that the paging device table entry currently associated with the vmid

object is not D\_REMOTE or is not valid.

EINVAL\_VM\_SETDEVID5 Indicates that the vm\_mount flags for the current and new paging device table

entries differ.

EINVAL\_VM\_SETDEVID6 Indicates that this was called at interrupt level. EINVAL\_VM\_SETDEVID7 Indicates that the input flags was nonzero. EINVAL\_VM\_SETDEVID8 Indicates that the input vmid value is not valid.

#### **Related Information**

The **vm mount** kernel service, **vm umount** kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm\_setseg\_kkey Kernel Service

### **Purpose**

Sets the default kernel-key for a segment.

### **Syntax**

```
#include <sys/types.h>
#include <sys/kerrno.h>
#include <sys/vmuser.h>
kerrno_t vm_setseg_kkey (vmid, kkey)
vmid_t vmid;
kkey_t kkey;
```

#### **Parameters**

vmid Virtual memory object to act on.

New kernel key for the virtual memory object. kkey

### **Description**

The vm\_setseg\_kkey kernel service alters the default kernel-key for newly allocated pages in a segment. The kernel-key values for any existing pages in the segment are left unchanged.

#### **Execution Environment**

The vm\_setseg\_kkey kernel service can be called from the process environment only.

#### **Return Values**

Successful.

EINVAL\_VM\_SETSEG\_KKEY Invalid parameter or execution environment.

#### **Related Information**

The vm\_protect\_kkey kernel service.

# vm\_thrpgio\_pop Kernel Service

# **Purpose**

Retrieves the latest context information.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
void vm thrpgio pop ( in ctxp)
ut_pgio_context_t * in_ctxp;
```

#### **Parameters**

in\_ctxp The context structure used by the function.

### **Description**

The vm\_thrpgio\_pop kernel service enables a client file system with a thread-level strategy routine to copy information from a context structure to the current thread. Afterwards, it makes the current thread point to the next context.

This service must be called if a client file system using a thread-level strategy routine has re-entered the Virtual Memory Manager and wishes to return to its strategy routine. This service restores the context that was saved using the vm thrpgio push kernel service.

#### **Execution Environment**

The vm thrpgio pop kernel service can only be used by client file systems using a thread-level strategy routine.

#### **Return Values**

The vm\_thrpgio\_pop kernel service has no return values.

#### **Related Information**

The vm\_thrpgio\_push kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vm\_thrpgio\_push Kernel Service

# **Purpose**

Saves some context information of the current thread.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
void vm_thrpgio_push ( in_ctxp)
ut_pgio_context_t * in_ctxp;
```

#### **Parameters**

The context structure used by the function. in\_ctxp

# **Description**

The vm\_thrpgio\_push kernel service enables a client file system with a thread-level strategy routine to save information about the current thread to a linked list. The linked list is a Last-In-First-Out (LIFO) (stack) data structure, and is pointed to by the thread.

This service must be called if a client file system using a thread-level strategy routine has had its strategy routine invoked and wishes to re-enter the Virtual Memory Manager. This could involve a page fault on one of its client segments, or the use of one of the Virtual Memory Manager (VMM) services that operates on client segments.

The vm\_thrpgio\_pop kernel service must be invoked when all such Virtual Memory Manager callbacks are complete.

#### **Execution Environment**

The vm\_thrpgio\_push kernel service can only be used by client file systems using a thread-level strategy routine.

#### **Return Values**

The vm\_thrpgio\_push kernel service has no return values.

#### Related Information

The vm\_thrpgio\_pop kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vms\_create Kernel Service

### **Purpose**

Creates a virtual memory object of the specified type, size, and limits.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vms create (vmid, type, devgno, size, uplim, downlim)
vmid_t * vmid;
int
    type;
dev_t devgno;
int
    size;
     uplim;
int
int
     downlim;
```

#### **Parameters**

vmid	Points to the variable in which the virtual memory object identifier is to be stored.
type	Specifies the virtual memory object type and options as an OR of bits. The type parameter must have
	the value of <b>V_CLIENT</b> . The <b>V_INTRSEG</b> flag specifies if the process can be interrupted from a page wait on this object.
devgno	Specifies the address of the g-node for client storage. If the type parameter has the value of
	<b>V_CLIENT</b> , the third argument is a g-node <i>ptr</i> argument, otherwise, it is a <i>devgno</i> argument.
size	Specifies the current size of the file (in bytes). This can be any valid file size. If the V_LARGE is specified, it is interpreted as number of pages.
uplim	Ignored. The enforcement of file size limits is done by comparing with the <b>u_limit</b> value in the <b>u</b> block.
downlim	Ignored.

### **Description**

The vms create kernel service creates a virtual memory object. The resulting virtual memory object identifier is passed back by reference in the vmid parameter.

The size parameter is used to determine the size in units of bytes of the virtual memory object to be created. This parameter sets an internal variable that determines the virtual memory range to be processed when the virtual memory object is deleted.

An entry for the file system is required in the paging device table when the vms\_create kernel service is called.

#### **Execution Environment**

The vms\_create kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

**ENOMEM** Indicates that no space is available for the virtual memory object. **ENODEV** Indicates no entry for the file system in the paging device table.

Indicates incompatible or bad parameters. EINVAL

#### **Related Information**

The vms delete kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vms delete Kernel Service

# **Purpose**

Deletes a virtual memory object.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vms delete ( vmid)
vmid t vmid;
```

#### **Parameter**

vmid Specifies the ID of the virtual memory object to be deleted.

# Description

The vms\_delete kernel service deallocates the temporary resources held by the virtual memory object specified by the vmid parameter and then frees the control block. This delete operation can complete asynchronously, but the caller receives a synchronous return code indicating success or failure.

#### Releasing Resources

The completion of the delete operation can be delayed if paging I/O is still occurring for pages attached to the object. All page frames not in the I/O state are released.

If there are page frames in the I/O state, they are marked for discard at I/O completion and the virtual memory object is placed in the iodelete state. When an I/O completion occurs for the last page attached to a virtual memory object in the iodelete state, the virtual memory object is placed on the free list.

#### **Execution Environment**

The vms\_delete kernel service can be called from the process environment only.

#### **Return Values**

0 Indicates a successful operation.

**EINVAL** Indicates that the *vmid* parameter is not valid.

#### **Related Information**

The vms\_create kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vms\_iowait, vms\_iowaitf Kernel Services

### **Purpose**

Waits for the completion of all page-out operations for pages in the virtual memory object.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>

int vms_iowait ( vmid)
vmid_t vmid;
int vms_iowaitf ( vmid, flags)
vmid_t vmid;
int flags;
```

#### **Parameter**

vmid Identifies the virtual memory object for which to wait.

flags Optional flags passed in by the user.

# **Description**

The **vms\_iowait** kernel service performs two tasks. First, it determines the I/O level at which all currently scheduled page-outs are complete for the virtual memory object specified by the *vmid* parameter. Then, the **vms\_iowait** service places the current process in a wait state until this I/O level has been reached.

The I/O level value is a count of page-out operations kept for each virtual memory object.

The I/O level accounts for out-of-order processing by not incrementing the I/O level for new page-out requests until all previous requests are complete. Because of this, processes waiting on different I/O levels can be awakened after a single page-out operation completes.

If the caller holds the kernel lock, the vms\_ iowait service releases the kernel lock before waiting and reacquires it afterwards.

The vms\_iowait function is a special case of the vms\_iowaitf function with the V\_WAITERR flag set.

### **Flags**

Name **Purpose** 

**V\_WAITERR** Waits until the completion of all I/O unless an error occurs.

**V WAITALL** Waits until the completion of all I/O regardless of any occurrence of I/O errors.

#### **Execution Environment**

The vms iowait and vms iowaitf kernel services can be called from the process environment only.

They can only be used by file segments.

### **Return Values**

Indicates that the page-out operations completed.

Indicates that an error occurred while performing I/O.

### **Related Information**

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm\_uiomove Kernel Service

# **Purpose**

Moves data between a virtual memory object and a buffer specified in the uio structure.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
#include <sys/uio.h>
int vm_uiomove (vmid, limit, rw, uio)
vmid t vmid;
int \overline{l} imit:
enum uio_rw rw;
struct uio *uio;
```

#### **Parameters**

vmid Specifies the virtual memory object ID.

Indicates the limit on the transfer length. If this parameter is negative or 0, no bytes are transferred. limit rw Specifies a read/write flag that gives the direction of the move. The possible values for this parameter

(UIO\_READ, UIO\_WRITE) are defined in the /usr/include/sys/uio.h file.

Points to the uio structure. uio

### **Description**

The vm uiomove kernel service moves data between a virtual memory object and the buffer specified in a uio structure.

This service determines the virtual addressing required for the data movement according to the offset in the object.

The vm uiomove kernel service is similar to the uiomove kernel service, but the address for the trusted buffer is specified by the vmid parameter and the uio offset field of offset parameters instead of as a caddr t address. The offset size is a 64 bit offset t, which allows file offsets in client segments which are greater than 2 gigabytes. vm uiomove must be used instead of vm move if the client filesystem supports files which are greater than 2 gigabytes.

Note: The vm uiomove kernel service does not support use of cross-memory descriptors.

I/O errors for paging space and a lack of paging space are reported as signals.

#### **Execution Environment**

The vm\_uiomove kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

**EFAULT** Indicates a bad address. **ENOMEM** Indicates insufficient memory. ENOSPC Indicates insufficient disk space.

EIO Indicates an I/O error.

Other file system-specific errno global variables are returned by the virtual file system involved in the move function.

#### **Related Information**

The **uiomove** kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm\_umount Kernel Service

# **Purpose**

Removes a file system from the paging device table.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm umount (type, devid)
int type;
dev_t devid)();
```

#### **Parameters**

type

Specifies the type of device. You can specify multiple values. But the type parameter must have a value of **D\_REMOTE** as one of its values. You can also specify the following optional value:

Indicates that if I/O discovered during a prior vm setdevid call has not yet completed, the paging device table entry will be removed, asynchronously, at a future point in time when all such I/O to it has completed. This particular vm\_umount kernel service call will return without waiting for the I/O to complete. Any buf structures associated with this paging device entry remain allocated until the paging device entry is finally removed.

Points to the strategy routine. devid

### **Description**

The vm\_umount kernel service waits for all I/O for the device scheduled by the pager to finish. This service then frees the entry in the paging device table. The associated buf structures are also freed.

#### **Execution Environment**

The vm\_umount kernel service can be called from the process environment only.

#### **Return Values**

Indicates successful completion.

**EINVAL** 

Indicates that a file system with the strategy routine designated by the devid parameter is not in the paging device table.

### **Related Information**

The vm\_mount kernel service, the vm\_setdevid kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### vm\_write Kernel Service

# Purpose

Initiates page-out for a page range in the address space.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
int vm_write (vaddr, nbytes, force)
int vaddr:
int nbytes;
int force;
```

# **Description**

The vm write kernel service initiates page-out for pages that intersect the address range (vaddr, vaddr + nbytes).

If the force parameter is nonzero, modified pages are written to disk regardless of how recently they have been written.

Page-out is initiated for each modified page. An unchanged page is left in memory with its reference bit set to 0. This makes the unchanged page a candidate for the page replacement algorithm.

The caller must have write access to the specified pages.

The initiated I/O is asynchronous. The vms\_iowait kernel service can be called to wait for I/O completion.

**Note:** The **vm\_write** subroutine is not supported for use on large pages.

#### **Parameters**

vaddr Specifies the address of the first byte of the page range for which a page-out is desired.

Specifies the number of bytes starting at the byte specified by the vaddr parameter. This parameter must nbytes

be nonnegative. All of the bytes must be in the same virtual memory object.

force Specifies a flag indicating that a modified page is to be written regardless of when it was last written.

#### **Execution Environment**

The vm\_write kernel service can be called from the process environment only.

#### **Return Values**

Indicates a successful completion.

**EINVAL** Indicates one of these four errors:

· A region is not defined.

· A region is an I/O region.

• The length specified by the *nbytes* parameter is negative.

· The address range crosses a virtual memory object boundary.

· One or more large pages lie in the target page range.

**EACCES** Indicates that access does not permit writing.

**EIO** Indicates a permanent I/O error.

### **Related Information**

The **vm\_writep** kernel service, **vms\_iowait** kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vm writep Kernel Service

# **Purpose**

Initiates page-out for a page range in a virtual memory object.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/vmuser.h>

```
int vm_writep ( vmid, pfirst, npages)
vmid t vmid;
int pfirst;
int npages;
```

# Description

The vm\_writep kernel service initiates page-out for the specified page range in the virtual memory object. I/O is initiated for modified pages only. Unchanged pages are left in memory, but their reference bits are set to 0.

The caller can wait for the completion of I/O initiated by this and prior calls by calling the vms\_iowait kernel service.

Note: The vm\_writep subroutine is not supported for use on large pages.

#### **Parameters**

vmid Specifies the identifier for the virtual memory object.

pfirst Specifies the first page number at which page-out is to begin.

Specifies the number of pages for which the page-out operation is to be performed. npages

## **Execution Environment**

The vm\_writep kernel service can be called from the process environment only.

### **Return Values**

Indicates successful completion.

**EINVAL** 

Indicates any one of the following errors:

- · The virtual memory object ID is not valid.
- · The starting page is negative.
- · The number of pages is negative.
- · The page range exceeds the size of virtual memory object.
- One or more large pages lie in the target page range.

### **Related Information**

The vm write kernel service, vms iowait kernel service.

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vn\_free Kernel Service

# Purpose

Frees a v-node previously allocated by the vn\_get kernel service.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
int vn_free ( vp)
struct vnode *vp;
```

Points to the v-node to be deallocated.

# **Description**

The vn free kernel service provides a mechanism for deallocating v-node objects used within the virtual file system. The v-node specified by the vp parameter is returned to the pool of available v-nodes to be used again.

### **Execution Environment**

The vn free kernel service can be called from the process environment only.

### Return Values

The vn free service always returns 0.

### **Related Information**

The vn\_get kernel service.

Virtual File System Overview and Virtual File System (VFS) Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vn get Kernel Service

# **Purpose**

Allocates a virtual node.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
int vn_get ( vfsp, gnp, vpp)
struct vfs *vfsp;
struct gnode *gnp;
struct vnode **vpp;
```

## **Parameters**

- Points to a vfs structure describing the virtual file system that is to contain the v-node. Any returned v-node vfsp belongs to this virtual file system.
- Points to the g-node for the object. This pointer is stored in the returned v-node. The new v-node is added to gnp the list of v-nodes in the g-node.
- vpp Points to the place in which to return the v-node pointer. This is set by the vn\_get kernel service to point to the newly allocated v-node.

# **Description**

The vn get kernel service provides a mechanism for allocating v-node objects for use within the virtual file system environment. A v-node is first allocated from an effectively infinite pool of available v-nodes.

Upon successful return from the vn\_get kernel service, the pointer to the v-node pointer provided (specified by the vpp parameter) has been set to the address of the newly allocated v-node.

The fields in this v-node have been initialized as follows:

Field	Initial Value
v_count	Set to 1.
v_vfsp	Set to the value in the vfsp parameter.
v_gnode	Set to the value in the gnp parameter.
v next	Set to list of others v-nodes with the same g-node.

All other fields in the v-node are zeroed.

### **Execution Environment**

The vn\_get kernel service can be called from the process environment only.

### **Return Values**

Indicates successful completion.

**ENOMEM** Indicates that the vn\_get kernel service could not allocate memory for the v-node. (This is a highly

unlikely occurrence.)

### **Related Information**

The vn\_free kernel service.

Virtual File System Overview and Virtual File System (VFS) Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### waitcfree Kernel Service

# **Purpose**

Checks the availability of a free character buffer.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/cblock.h>
#include <sys/sleep.h>
int waitcfree ()
```

# **Description**

The waitcfree kernel service is used to wait for a buffer which was allocated by a previous call to the pincf kernel service. If one is not available, the waitcfree kernel service waits until either a character buffer becomes available or a signal is received.

The waitcfree kernel service has no parameters.

### **Execution Environment**

The waitfree kernel service can be called from the process environment only.

## **Return Values**

**EVENT\_SUCC** Indicates a successful operation.

EVENT\_SIG Indicates that the wait was terminated by a signal.

#### **Related Information**

The pincf kernel service, putc kernel service, putcb kernel service, putcb kernel service, putcf kernel service, putcfl kernel service, putcx kernel service.

I/O Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# waitq Kernel Service

# **Purpose**

Waits for a queue element to be placed on a device queue.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/deviceq.h>
struct req_qe *waitq ( queue id)
cba id queue id;
```

## **Parameter**

queue\_id Specifies the device queue identifier.

# **Description**

The waitq kernel service is not part of the base kernel but is provided by the device queue management kernel extension. This queue management kernel extension must be loaded into the kernel before loading any kernel extensions referencing these services.

The waitq kernel service waits for a queue element to be placed on the device queue specified by the *queue\_id* parameter. This service performs these two actions:

- Waits on the event mask associated with the device queue.
- Calls the **readq** kernel service to make the most favored queue element the active one.

Processes can only use the waitq kernel service to wait for a single device queue. Use the et wait service to wait on the occurrence of more than one event, such as multiple device queues.

The waitq kernel service uses the EVENT\_SHORT form of the et\_wait kernel service. Therefore, a signal does not terminate the wait. Use the et wait kernel service if you want a signal to terminate the wait.

The **readq** kernel service can be used to read the active queue element from a queue. It does not wait for a queue element if there are none in the queue.

Attention: The server must not alter any fields in the queue element or the system may halt.

#### **Execution Environment**

The waitq kernel service can be called from the process environment only.

## **Return Values**

The waitq service returns the address of the active queue element in the device queue.

#### **Related Information**

The et wait kernel service.

# WPAR CKPT QUERY (Checkpoint Query) Device Driver loctl Operation

# **Purpose**

Queries a device driver about its checkpoint capabilities.

# **Syntax**

```
#include <sys/ioctl.h>
int ioctl (FileDescriptor, WPAR_CKPT_QUERY, Arg )
int FileDescriptor;
wpar_ckpt_resp_t * Arg;
```

### **Parameters**

FileDescriptor WPAR\_CKPT\_QUERY Arg

Open file descriptor that refers to the device being queried for the checkpoint capability.

The command that requests information on the device checkpoint capability.

Pointer to a wpar\_ckpt\_resp\_t structure which will contain a device driver response on the

checkpoint capability upon a successful return from the ioctl call.

# **Description**

The WPAR CKPT QUERY operation allows a caller to ask a device driver connected to the ioctl input file descriptor if it supports checkpoint and restart operations. If a device driver supports checkpoint and restart operations, the returned answer can describe what operations are required to accomplish a checkpoint and restart.

If the device is not checkpoint and restart capable, checkpoint-aware devices fail this ioctl request with the **ENOSYS** error. Non-checkpoint-aware devices fail this ioctl request as an unknown ioctl. If the device is checkpoint and restart capable, checkpoint-aware devices return success.

The arg parameter to a WPAR CKPT QUERY ioctl request allows the caller to receive specific information regarding how the device supports checkpoint and restart if it is capable. The caller of a WPAR CKPT QUERY ioctl request must supply a pointer to a structure of the wpar ckpt resp t type in the arg parameter.

# wpar\_ckpt\_resp\_t structure

The wpar ckpt resp t structure is supplied as the input to the WPAR CKPT QUERY ioctl request.

```
#define WPAR_CKPT_OP_MAX 5
typedef struct wpar_ckpt_resp_t {
int opent;
wpar_ckpt_op_top [WPAR_CKPT_OP_MAX];
}wpar_ckpt_resp_t;
```

The fields of the **wpar\_ckpt\_resp\_t** structure are as follows:

opcnt Returned from an WPAR\_CKPT\_QUERY loctl request as the number of the

wpar\_ckpt\_op\_t sub-structures that contain return information.

wpar\_ckpt\_op\_top A sub-structure that contains specific information on operation types that must

occur on a device for it to save or restore its state correctly.

# wpar\_ckpt\_op\_t structure

The wpar\_ckpt\_op\_t structure is a sub-structure of the wpar\_ckpt\_resp\_t structure.

```
typedef struct wpar_ckpt_op_t {
int op;
int opt; /*extended options of openx*/
}wpar_ckpt_op_t;
```

The fields of the wpar\_ckpt\_op\_t structure are as follows:

op Returned from a WPAR\_CKPT\_QUERY ioctl request. Defined as a set of one or

more operations that must be performed to successfully checkpoint and restart

the device.

opt Options to supply to the openx function if the device is to be re-opened on the

arrival server through the openx function.

# wpar\_ckpt\_op\_t op field

**WPAR\_CKPT\_OP\_NULL** Device requires no special handling for checkpoint and restart operations.

WPAR\_CKPT\_OP\_REOPEN Device needs to be re-opened through the open function with the access modes

applicable at checkpoint time.

WPAR\_CKPT\_OP\_OPENX Device needs to be re-opened with the openx function. The opt field denotes the

desired extension argument to the openx function.

#### **Return Values**

Upon successful completion, this operation returns a value of 0. Otherwise, it returns a value of -1 and the errno global variable is set to one of the following values:

ENOSYS

Device cannot participate in checkpoint and restart operations.

Device does not accept the WPAR\_CKPT\_QUERY operation.

### **Related Information**

The kwpar\_checkpoint\_status kernel service.

# w\_clear Kernel Service

# **Purpose**

Removes a watchdog timer from the list of watchdog timers known to the kernel.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/watchdog.h>

int w_clear ( w)
struct watchdog *w;
```

w Specifies the watchdog timer structure.

# **Description**

The watchdog timer services, including the **w\_clear** kernel service, are typically used to verify that an I/O operation completes in a reasonable time.

When the **w\_clear** kernel service removes the watchdog timer, the *w*->**count** watchdog count is no longer decremented. In addition, the *w*->**func** watchdog timer function is no longer called.

In a uniprocessor environment, the call always succeeds. This is untrue in a multiprocessor environment, where the call will fail if the watchdog timer is being handled by another processor. Therefore, the function now has a return value, which is set to 0 if successful, or -1 otherwise. Funnelled device drivers do not need to check the return value since they run in a logical uniprocessor environment. Multiprocessor-safe and multiprocessor-efficient device drivers need to check the return value in a loop. In addition, if a driver uses locking, it must release and reacquire its lock within this loop, as shown below:

### **Execution Environment**

The w clear kernel service can be called from the process environment only.

### **Return Values**

- Indicates that the watchdog timer was successfully removed.
- -1 Indicates that the watchdog timer could not be removed.

#### **Related Information**

The w\_init kernel service, w\_start kernel service, w\_stop kernel service.

Timer and Time-of-Day Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# w\_init Kernel Service

# **Purpose**

Registers a watchdog timer with the kernel.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/watchdog.h>
int w_init ( w)
struct watchdog *w;
```

### **Parameter**

Specifies the watchdog timer structure.

# Description

The watchdog structure must be initialized prior to calling the w\_init kernel service as follows:

- Set the next and prev fields to NULL.
- · Set the func and restart fields to the appropriate values.
- · Set the count field to 0.

Attention: The watchdog structure must be pinned when the w\_init service is called. It must remain pinned until after the call to the w\_clear service. During this time, the watchdog structure must not be altered except by the watchdog services.

The watchdog timer services, including the w\_init kernel service, are typically used to verify that an I/O operation completes in a reasonable time. The watchdog timer is initialized to the stopped state and must be started using the w\_start service.

In both uniprocessor and multiprocessor environments, the w\_init kernel service always succeeds.

The calling parameters for the watchdog timer function are:

```
void func (w)
struct watchdog *w;
```

### **Execution Environment**

The w\_init kernel service can be called from the process environment only.

## **Return Values**

The w init kernel service returns 0 for compatibility with previous releases of AIX®.

### **Related Information**

The w\_clear kernel service, w\_start kernel service, w\_stop kernel service.

Timer and Time-of-Day Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# w start Kernel Service

# **Purpose**

Starts a watchdog timer.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/watchdog.h>
void w_start ( w)
struct watchdog *w;
```

#### **Parameter**

Specifies the watchdog timer structure.

# **Description**

The watchdog timers, including the w\_start kernel service, are typically used to verify that an I/O operation completes in a reasonable time. The w\_start and w\_stop kernel services are designed to allow the timer to be started and stopped efficiently. The kernel decrements the w->count watchdog count every second. The kernel calls the w->func watchdog timer function when the w->count watchdog count reaches 0. A watchdog timer is ignored when the w->count watchdog count is less than or equal to 0.

The w\_start kernel service sets the w->count watchdog count to a value of w->restart.

Attention: The watchdog structure must be pinned when the w\_start kernel service is called. It must remain pinned until after the call to the w clear kernel service. During this time, the watchdog structure must not be altered except by the watchdog services.

## **Execution Environment**

The w start kernel service can be called from the process and interrupt environments.

### Return Values

The w start kernel service has no return values.

### **Related Information**

The w clear kernel service, w init kernel service, w stop kernel service.

Timer and Time-of-Day Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# w\_stop Kernel Service

# **Purpose**

Stops a watchdog timer.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/watchdog.h>
void w_stop ( w)
struct watchdog *w;
```

### **Parameter**

Specifies the watchdog timer structure.

# **Description**

The watchdog timer services, including the w stop kernel service, are typically used to verify that an I/O operation completes in a reasonable time. The w\_start and w\_stop kernel services are designed to allow the timer to be started and stopped efficiently. The kernel decrements the w->count watchdog count every second. The kernel calls the w->func watchdog timer function when the w->count watchdog count reaches 0. A watchdog timer is ignored when w->count is less than or equal to 0.

Attention: The watchdog structure must be pinned when the w stop kernel service is called. It must remain pinned until after the call to the w clear kernel service. During this time, the watchdog structure must not be altered except by the watchdog services.

### **Execution Environment**

The **w\_stop** kernel service can be called from the process and interrupt environments.

## **Return Values**

The w stop kernel service has no return values.

### **Related Information**

The w\_clear kernel service, w\_init kernel service, w\_start kernel service.

Timer and Time-of-Day Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# xlate create Kernel Service

# **Purpose**

Creates pretranslation data structures.

# Syntax

```
int xlate_create (dp, baddr, count, flags)
struct xmem*dp;
caddr t baddr;
int count;
uint flags;
```

# Description

The xlate\_create kernel service creates pretranslation data structures capable of pretranslating all pages of the virtual buffer indicated by the baddr parameter for length of count into a list of physical page numbers, appended to the cross memory descriptor pointed to by dp.

If the XLATE ALLOC flag is set, only the data structures are created and no pretranslation is done. If the flag is not set, in addition to the data structures being created, each page of the buffer is translated and the access permissions verified, requiring read-write access to each page. The XLATE\_ALLOC flag is useful when the buffer will be pinned and utilized later, through the xlate pin and xlate unpin kernel services.

The XLATE\_SPARSE flag can be used to indicate that only selected portions of a pretranslated region may be valid (pinned and pretranslated) at any given time. The XLATE SPARSE flag can be used in conjunction with the XLATE ALLOC flag to preallocate the pretranslation data structures for an address region that will be dynamically managed.

The xlate create kernel service is primarily for use when memory buffers will be reused for I/O. The use of this service to create a pretranslation for the memory buffer avoids page translation and access checking overhead for all future DMAs involving the memory buffer until the xlate\_remove kernel service is called.

### **Parameters**

dp Points to the cross memory descriptor.

baddr Points to the virtual buffer.

Specifies the length of the virtual buffer. count

Specifies the operation. Valid values are as follows: flags

#### **XLATE PERSISTENT**

Indicates that the pretranslation data structures should be persistent across calls to pretranslation services.

#### XLATE ALLOC

Indicates that the pretranslation data structures should be allocated only, and no translation should be performed.

#### XLATE\_SPARSE

Indicates that the pretranslation information will be sparse, allowing for the coexistence of valid (active) pretranslation regions and invalid (inactive) pretranslation regions.

### **Return Values**

**ENOMEM** Unable to allocate memory

XMEM FAIL No physical translation, or No Access to a Page

XMEM\_SUCC Successful pretranslation created

### **Execution Environment**

The xlate\_create kernel service can only be called from the process environment. The entire buffer must be pinned (unless the XLATE ALLOC flag is set), and the cross memory descriptor valid.

## Related Information

"xlate\_remove Kernel Service" on page 570, "xm\_mapin Kernel Service" on page 572, "xm\_det Kernel Service" on page 571, "xlate\_pin Kernel Service," or "xlate\_unpin Kernel Service" on page 571.

# xlate\_pin Kernel Service

# Purpose

Pins all pages of a virtual buffer.

# **Syntax**

```
int xlate pin (dp, baddr, count, rw)
struct xmem *dp;
caddr_t baddr;
int count;
int rw;
```

# **Description**

The **xlate** pin kernel service pins all pages of the virtual buffer indicated by the baddr parameter for length of count and also appends pretranslation information to the cross memory descriptor pointed to by the *dp* parameter.

The xlate pin kernel service results in a short-term pin, which will support mmap and shmatt allocated memory buffers.

In addition to pinning and translating each page, the access permissions to the page are verified according to the desired access (as specified by the rw parameter). For a setting of **B READ**, write access to the page must be allowed. For a setting of **B WRITE**, only read access to the page must be allowed.

The caller can preallocate pretranslation data structures and append them to the cross memory descriptor prior to the call (through a call to the **xlate\_create** kernel service), or have this service allocate the necessary data structures. If the cross memory descriptor is already of type **XMEM\_XLATE**, it is assumed that the data structures are already allocated. If callers want to have the pretranslation data structures persist across the subsequent **xlate\_unpin** call, they should also set the **XLATE\_PERSISTENT** flag on the call to the **xlate create** kernel service.

### **Parameters**

dp Points to the cross memory descriptor.

baddr Points to the virtual buffer.

count Specifies the length of the virtual buffer.

rw Specifies the access permissions for each page.

### **Return Values**

If successful, the xlate\_pin kernel service returns 0. If unsuccessful, one of the following is returned:

**EINVAL** Invalid cross memory descriptor or parameters.

ENOMEMUnable to allocate memory.ENOSPCOut of Paging Resources.XMEM\_FAILPage Access violation.

#### **Execution Environment**

The **xlate\_pin** kernel service is only callable from the process environment, and the cross memory descriptor must be valid.

#### **Related Information**

"xlate\_create Kernel Service" on page 568, "xlate\_remove Kernel Service," "xm\_det Kernel Service" on page 571, "xm\_mapin Kernel Service" on page 572, or "xlate\_unpin Kernel Service" on page 571.

# xlate remove Kernel Service

# **Purpose**

Removes physical translation information from an xmem descriptor from a prior **xlate create** call.

# **Syntax**

caddr\_t xlate\_remove (dp)
struct xmem \*dp;

# **Description**

See the xlate create kernel service.

#### **Parameters**

dp Points to the cross memory descriptor.

#### **Return Values**

**XMEM\_FAIL** No pretranslation information present in the xmem descriptor.

XMEM\_SUCC Pretranslation successfully removed.

### **Execution Environment**

The xlate\_remove kernel service can only be called from the process environment.

#### Related Information

"xlate\_create Kernel Service" on page 568, "xm\_mapin Kernel Service" on page 572, "xm\_det Kernel Service," "xlate pin Kernel Service" on page 569, or "xlate unpin Kernel Service."

# xlate\_unpin Kernel Service

# **Purpose**

Unpins all pages of a virtual buffer.

# **Syntax**

int xlate\_unpin (dp, baddr, count) struct xmem \*dp; caddr t baddr; int count;

# **Description**

The xlate\_unpin kernel service unpins pages from a prior call to the xlate\_pin kernel service based on the baddr and count parameters. It does this by utilizing the pretranslated real page numbers appended to the cross memory descriptor pointed to by dp.

If the XLATE\_PERSISTENT flag is not set in the prexflags flag word of the pretranslation data structure, the pretranslation data structures are also freed.

#### **Parameters**

dp Points to the cross memory descriptor.

baddr Points to the virtual buffer.

count Specifies the length of the virtual buffer.

### **Return Values**

If successful, the xlate\_unpin kernel service returns 0. If unsuccessful, one of the following is returned:

**EINVAL** Invalid cross memory descriptor or parameters.

**ENOSPC** Unable to allocate paging space (case of **mmap** segment).

**ENOSPC** Out of Paging Resources. XMEM\_FAIL Page Access violation.

#### **Related Information**

"xlate\_create Kernel Service" on page 568, "xlate\_remove Kernel Service" on page 570, "xm\_det Kernel Service," "xm\_mapin Kernel Service" on page 572, or "xlate\_pin Kernel Service" on page 569.

# xm det Kernel Service

# **Purpose**

Releases the addressability to the address space described by an xmem descriptor.

# **Syntax**

```
void xm_det (baddr, dp)
caddr t baddr;
struct xmem *dp;
```

# **Description**

See the **xm** mapin Kernel Service for more information.

### **Parameters**

haddr Specifies the effective address previously returned from the xm\_mapin kernel service.

dp Cross memory descriptor that describes the above memory object.

### **Related Information**

"xlate\_create Kernel Service" on page 568, "xlate\_remove Kernel Service" on page 570, "xm\_mapin Kernel Service," "xlate pin Kernel Service" on page 569, or "xlate unpin Kernel Service" on page 571.

# xm\_mapin Kernel Service

# **Purpose**

Sets up addressability in the current process context.

# **Syntax**

```
#include <sys/adspace.h>
int xm mapin (dp, baddr, count, eaddr)
struct xmem *dp;caddr t baddr;
size_t count;
caddr_t *eaddr;
```

# Description

The xm\_mapin kernel service sets up addressability in the current process context to the address space indicated by the cross memory descriptor pointed to by the dp parameter for the addresses [baddr, baddr + count - 1].

This service is created specifically for Client File Systems, or others who need to setup addressability to an address space defined by an xmem descriptor.

If the requested mapping spans a segment boundary, no mapping will be performed, and a return code of **EAGAIN** is returned to indicate that individual calls to the **xm** mapin kernel service are necessary to map the portions of the buffer in each segment. The xm\_mapin kernel service must be called again with the original baddr and a count indicating the number of bytes to the next segment. (The number of bytes to the next segment boundary can be obtained using the xm\_maxmap kernel service.) This will provide an effective address to use for accessing this portion of the buffer. Then, iteratively, **xm mapin** must be called with the segment boundary address (previous baddr + count), and a new count indicating the remainder of the buffer or the next segment boundary, whichever is smaller. This will provide another effective address to use for accessing the next portion of the buffer.

Each address set up by the xm mapin kernel service must be undone with the xm det kernel service when it is no longer needed because the xm mapin kernel service currently uses the vm att kernel service.

Points to the cross memory descriptor. dp

baddr Points to the virtual buffer.

count Specifies the length of the virtual buffer to map.

eaddr Points to where the effective address to access the data buffer is returned.

### **Return Values**

Successful. (Reference Parameter eaddr contains the

address to use)

XMEM FAIL Invalid cross memory descriptor.

**EAGAIN** Segment boundary crossing encountered. Caller should

make separate xm\_mapin calls to map each segments

### **Execution Environment**

The **xm\_mapin** kernel service can be called from the process or interrupt environments.

## **Related Information**

"xlate\_create Kernel Service" on page 568, "xlate\_remove Kernel Service" on page 570, "xlate\_pin Kernel Service" on page 569, "xlate\_unpin Kernel Service" on page 571, "xm\_det Kernel Service" on page 571, "vm\_att Kernel Service" on page 518 and "xm\_maxmap Kernel Service."

# xm maxmap Kernel Service

# **Purpose**

Determines the maximum permissible count value for a subsequent call to **xm\_mapin**.

# **Syntax**

```
#include <sys/adspace.h>
```

```
int xm_maxmap (dp, uaddr, len)
struct xmem *dp;
void *uaddr;
size t *len;
```

#### **Parameters**

dp Points to the cross memory descriptor.

uaddr Points to the virtual buffer.

len Points to where the maximum permissible count is returned.

# **Description**

The xm\_maxmap kernel service determines the maximum permissible count value (in bytes) for a subsequent **xm** mapin call. The value is determined based on the input cross-memory descriptor dp and the starting address uaddr, and it is returned in the len parameter. There is no guarantee that xm\_mapin will succeed; however, it is guaranteed that uaddr + \*len - 1 is in the same segment as uaddr, and therefore xm mapin will not return EAGAIN.

## **Execution Environment**

The xm maxmap interface can be called from the process or interrupt environment.

### **Return Values**

XMEM\_SUCC Successful (Reference parameter len contains the maximum permissible value for a

subsequent xm\_mapin call)

**XMEM FAIL** Invalid cross memory descriptor.

**EAGAIN** Segment boundary crossing encountered. Caller should make separate xm\_mapin calls to

map each segment's worth.

### **Related Information**

The "xm\_mapin Kernel Service" on page 572.

### xmalloc Kernel Service

# **Purpose**

Allocates memory.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/malloc.h>
caddr t xmalloc (size, align, heap)
int size;
int align;
caddr_t heap;
```

#### **Parameters**

size Specifies the number of bytes to allocate.

Specifies the alignment characteristics for the allocated memory. align

heap Specifies the address of the heap from which the memory is to be allocated.

# **Description**

The **xmalloc** kernel service allocates an area of memory out of the heap specified by the *heap* parameter. This area is the number of bytes in length specified by the size parameter and is aligned on the byte boundary specified by the align parameter. The align parameter is actually the log base 2 of the desired address boundary. For example, an align value of 4 requests that the allocated area be aligned on a 2<sup>4</sup> (16) byte boundary.

There are multiple heaps provided by the kernel for use by kernel extensions. Two primary kernel heaps are kernel heap and pinned heap. Kernel extensions should use the kernel heap value when allocating memory that is not pinned, and should use the pinned heap value when allocating memory that should always be pinned or pinned for long periods of time. When allocating from the pinned heap heap, the xmalloc kernel service will pin the memory before a successful return. The pin and unpin kernel services should be used to pin and unpin memory from the kernel heap heap when the memory should only be pinned for a limited amount of time. Memory from the kernel\_heap heap must be unpinned before freeing it. Memory from the **pinned heap** heap should not be unpinned.

The kernel heap heap points to one of the following heaps: kernel heap 4K 64K and kernel heap 16M. The pinned heap heap points to one of the following heaps: pinned heap 4K 64K and pinned\_heap\_16M. Each of the target heaps differ in the size of the pages that back them. kernel\_heap\_4K\_64K or pinned\_heap\_4K\_64K will be backed by either medium (64 KB) or regular (4 KB) pages, depending on the page size supported by the machine. kernel heap 16M or pinned heap 16M will return memory backed by large pages if large page heaps are enabled. If large page heaps are not enabled, kernel\_heap or pinned\_heap will point to the default heap. If the size of the backing pages are not important, use the **kernel heap** value and the **pinned heap** value. They will point to the heap that you prefer. For more information about large page heap support, see vmo.

Kernel extensions can use these services to allocate memory out of the kernel heaps. For example, the xmalloc (128,3,kernel heap) kernel service allocates a 128-byte double word aligned area out of the kernel heap.

A kernel extension must use the xmfree kernel service to free the allocated memory. If it does not, subsequent allocations eventually are unsuccessful.

The **xmalloc** kernel service has two compatibility interfaces: **malloc** and **palloc**.

The following additional interfaces to the **xmalloc** kernel service are provided:

- malloc (size) is equivalent to xmalloc (size, 0, kernel heap).
- palloc (size, align) is equivalent to xmalloc (size, align, kernel heap).

### **Execution Environment**

The **xmalloc** kernel service can be called from the process environment only.

### Return Values

Upon successful completion, the xmalloc kernel service returns the address of the allocated area. A null pointer is returned under the following circumstances:

- · The requested memory cannot be allocated.
- The heap has not been initialized for memory allocation.

#### Related Information

The xmfree kernel service.

Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### xmattach Kernel Service

# **Purpose**

Attaches to a user buffer for cross-memory operations.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>
int xmattach (addr, count, dp, segflag)
char * addr;
```

int count: struct xmem \* dp; int segflag;

## **Parameters**

addr Specifies the address of the user buffer to be accessed in a cross-memory operation. count Indicates the size of the user buffer to be accessed in a cross-memory operation.

Specifies a cross-memory descriptor. The dp->aspace\_id variable must be set to a value of dp

XMEM\_INVAL.

Specifies a segment flag. This flag is used to determine the address space of the memory that the segflag

cross-memory descriptor applies to, as well as for other purposes. The valid values for this flag can be

found in the /usr/include/xmem.h file.

# **Description**

The **xmattach** kernel service prepares the user buffer so that a device driver can access it without executing under the process that requested the I/O operation. A device top-half routine calls the xmattach kernel service. The xmattach kernel service allows a kernel process or device bottom-half routine to access the user buffer with the xmemin or xmemout kernel services. The device driver must use the xmdetach kernel service to inform the kernel when it has finished accessing the user buffer.

The kernel remembers which segments are attached for cross-memory operations. Resources associated with these segments cannot be freed until all cross-memory descriptors have been detached. "Cross Memory Kernel Services" in Memory Kernel Services in in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts describes how the cross-memory kernel services use cross-memory descriptors.

Note: When the xmattach kernel service remaps user memory containing the cross-memory buffer, the effects are machine-dependent. Also, cross-memory descriptors are not inherited by a child process.

Storage-key protection can be enforced on memory regions described by a cross-memory descriptor. The enforcement is done during normal access checking performed by cross-memory services, such as the xmemdma kernel service. A kernel keyset can be contained in the cross-memory descriptor to limit memory accessibility. When a keyset is associated with a cross-memory descriptor, access to the memory region is limited by that keyset. A keyset is required because a cross-memory descriptor can describe a virtual memory region with multiple keys assigned to the pages it contains. Normally, a keyset describes the accessibility of the context that the attach was initiated for. For example, a cross-memory attached to user-space contains a description of the user-mode accessibility (keyset). Adding keysets to kernel cross-memory descriptors can also enhance system RAS, since they limit kernel access by the cross-memory descriptor. Typically it is limited to that of the xmattach caller or to specific key(s), to catch cases where a cross-memory descriptor is misused.

User-mode storage-keys are always associated with descriptors attached using USER SPACE or USERI SPACE segflag. These flags were always required to attach to the user address space, so no explicit update is required to enable storage-key protection on user memory attaches. Once attached, existing kernel services that require cross-memory descriptors enforce the user keyset saved at attach time when performing memory accesses or checking user accessibility.

For kernel memory, a keyset is not used to restrict regions attached with SYS\_ADSPACE. Attaching a region with SYS\_ADSPACE\_ASSIGN\_KEYSET associates the caller's keyset with the cross-memory region.

### **Execution Environment**

The **xmattach** kernel service can be called from the process environment only.

#### **Return Values**

XMEM\_SUCC XMEM\_FAIL

Indicates a successful operation. Indicates one of the following errors:

- The buffer size indicated by the *count* parameter is less than or equal to 0.
- The cross-memory descriptor is in use (dp->aspace\_id != XMEM\_INVAL).
- The area of memory indicated by the addr and count parameters is not defined.

## **Related Information**

The uphysio kernel service, xmdetach kernel service, xmemin kernel service, and xmemout kernel service.

The xmsethkeyset, xmgethkeyset kernel services.

Cross Memory Kernel Services, and Memory Kernel Services.

### xmdetach Kernel Service

# **Purpose**

Detaches from a user buffer used for cross-memory operations.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>
int xmdetach (dp)
struct xmem *dp;
```

#### **Parameter**

dp Points to a cross-memory descriptor initialized by the **xmattach** kernel service.

# **Description**

The **xmdetach** kernel service informs the kernel that a user buffer can no longer be accessed. This means that some previous caller, typically a device driver bottom half or a kernel process, is no longer permitted to do cross-memory operations on this buffer. Subsequent calls to either the xmemin or xmemout kernel service using this cross-memory descriptor result in an error return. The cross-memory descriptor is set to dp->aspace\_id = XMEM\_INVAL so that the descriptor can be used again. "Cross Memory Kernel Services in Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts describes how the cross-memory kernel services use cross-memory descriptors.

## **Execution Environment**

The **xmdetach** kernel service can be called from either the process or interrupt environment.

## **Return Values**

XMEM\_SUCC Indicates successful completion.

XMEM\_FAIL Indicates that the descriptor was not valid or the buffer was not defined.

### **Related Information**

The **xmattach** kernel service, **xmemin** kernel service, **xmemout** kernel service.

Cross Memory Kernel Services and Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## xmemdma Kernel Service

# **Purpose**

Prepares a page for direct memory access (DMA) I/O or processes a page after DMA I/O is complete.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>
int xmemdma (xp, xaddr, flag)
struct xmem *xp;
caddr_t xaddr;
int flag;
```

## **Parameters**

Specifies a cross-memory descriptor.

xaddr Identifies the address specifying the page for transfer.

flag Specifies whether to prepare a page for DMA I/O or process it after DMA I/O is complete. Possible values

## XMEM\_ACC\_CHK

Performs access checking on the page. When this flag is set, the page protection attributes are verified.

### XMEM\_DR\_SAFE

Indicates that the use of the real memory address is DLPAR safe.

#### XMEM\_HIDE

Prepares the page for DMA I/O. For cache-inconsistent platforms, this preparation includes hiding the page by making it inaccessible.

#### XMEM\_UNHIDE

Processes the page after DMA I/O. Also, this flag reveals the page and makes it accessible for cache-inconsistent platforms.

#### XMEM\_WRITE\_ONLY

Marks the intended transfer as outbound only. This flag is used with XMEM\_ACC\_CHK to indicate that read-only access to the page is sufficient.

# **Description**

The **xmemdma** kernel service operates on the page specified by the *xaddr* parameter in the region specified by the cross-memory descriptor. If the cross-memory descriptor is for the kernel, the xaddr parameter specifies a kernel address. Otherwise, the xaddr parameter specifies the offset in the region described in the cross-memory descriptor.

The **xmemdma** kernel service is provided for machines that have processor-memory caches, but that do not perform DMA I/O through the cache. Device handlers for Micro Channel DMA devices use the d\_master service and d\_complete kernel service instead of the xmemdma kernel service.

If the flag parameter indicates **XMEM HIDE** (that is, **XMEM UNHIDE** is not set) and this is the first hide for the page, the xmemdma kernel service prepares the page for DMA I/O by flushing the cache and making the page invalid. When the XMEM\_UNHIDE bit is set and this is the last unhide for the page, the following events take place:

- 1. The page is made valid. If the page is not in pager I/O state:
- 2. Any processes waiting on the page are readied.
- 3. The modified bit for the page is set unless the page has a read-only storage key.

The page is made not valid during DMA operations so that it is not addressable with any virtual address. This prevents any process from reading or loading any part of the page into the cache during the DMA operation.

The page specified must be in memory and must be pinned.

If the XMEM ACC CHK bit is set, then the xmemdma kernel service also verifies access permissions to the page. If the page access is read-only, then the **XMEM WRITE ONLY** bit must be set in the flag parameter.

#### Note:

- 1. The **xmemdma** kernel service does not hide or reveal the page nor does it perform any cache flushing. The service's primary function is for real-address translation.
- 2. This service is not supported for large-memory systems with greater than 4GB of physical memory addresses. For such systems, xmemdma64 should be used.

### **Execution Environment**

The **xmemdma** kernel service can be called from either the process or interrupt environment.

#### **Return Values**

On successful completion, the **xmemdma** service returns the real address corresponding to the *xaddr* and xp parameters.

#### **Error Codes**

The **xmemdma** kernel service returns a value of **XMEM FAIL** if one of the following are true:

- The descriptor was invalid.
- The page specified by the *xaddr* or *xp* parameter is invalid.
- · Access is not allowed to the page.

### **Related Information**

Cross Memory Kernel Services and Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

Understanding Direct Memory Access (DMA) Transfer.

Dynamic Logical Partitioning in AIX® Version 7.1 General Programming Concepts: Writing and Debugging Programs.

# xmemdma64 Kernel Service

# **Purpose**

Prepares a page for direct memory access (DMA) I/O or processes a page after DMA I/O is complete.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>
unsigned long long xmemdma64 (
struct xmem *dp,
caddr_t xaddr,>
int f\overline{l}ags)
```

### **Parameters**

flags

dp Specifies a cross-memory

descriptor.

xaddr Identifies the address specifying the page for transfer.

Specifies whether to prepare a page for DMA I/O or process it after DMA I/O is

complete. Possible values are:

#### XMEM\_HIDE

Prepares the page for DMA I/O. If cache-inconsistent, then the data cache is flushed, the memory page is hidden, and the real page address is returned. If cache-consistent, then the modified bit is set and the real address of the page is returned.

#### **XMEM UNHIDE**

Processes the page after DMA I/O. Also, this flag reveals the page, readies any processes waiting on the page, and sets the modified bit accordingly.

#### XMEM\_ACC\_CHK

Performs access checking on the page. When this flag is set, the page protection attributes are verified.

## XMEM\_WRITE\_ONLY

Marks the intended transfer as outbound only. This flag is used with **XMEM\_ACC\_CHK** to indicate that read-only access to the page is sufficient.

# **Description**

The **xmemdma64** kernel service operates on the page specified by the *xaddr* parameter in the region specified by the cross-memory descriptor. If the cross-memory descriptor is for the kernel, the xaddr parameter specifies a kernel address. Otherwise, the xaddr parameter specifies the offset in the region described in the cross-memory descriptor.

The xmemdma64 kernel service is provided for machines that have processor-memory caches, but that do not perform DMA I/O through the cache. Device handlers for Micro Channel DMA devices (running AIX® 5.1 or earlier) use the d\_master service and d\_complete kernel service instead of the xmemdma64 kernel service.

If the flag parameter indicates XMEM\_HIDE (that is, XMEM\_UNHIDE is not set) and this is the first hide for the page, the xmemdma64 kernel service prepares the page for DMA I/O by flushing the cache and making the page invalid. When the XMEM\_UNHIDE bit is set and this is the last unhide for the page, the following events take place:

- 1. The page is made valid. If the page is not in pager I/O state:
- 2. Any processes waiting on the page are readied.
- 3. The modified bit for the page is set unless the page has a read-only storage key.

The page is made not valid during DMA operations so that it is not addressable with any virtual address. This prevents any process from reading or loading any part of the page into the cache during the DMA operation.

The page specified must be in memory and must be pinned.

If the XMEM ACC CHK bit is set, then the xmemdma64 kernel service also verifies access permissions to the page. If the page access is read-only, then the XMEM WRITE ONLY bit must be set in the flag parameter.

Note: The xmemdma64 kernel service does not hide or reveal the page, nor does it perform any cache flushing. The service's primary function is for real-address translation.

### **Execution Environment**

The xmemdma64 kernel service can be called from either the process or interrupt environment.

## **Return Values**

On successful completion, the **xmemdma64** service returns the real address corresponding to the *xaddr* and xp parameters.

### **Error Codes**

The xmemdma64 kernel service returns a value of XMEM\_FAIL if one of the following are true:

- · The descriptor was invalid.
- The page specified by the xaddr or xp parameter is invalid.
- · Access is not allowed to the page.

### **Related Information**

Cross Memory Kernel Services and Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

Understanding Direct Memory Access (DMA) Transfer.

# xmempin Kernel Service

# **Purpose**

Pins the specified address range in user or system memory.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/uio.h>

```
int xmempin( base, len, xd)
caddr t base;
int len;
struct xmem *xd;
```

base Specifies the address of the first byte to pin. Indicates the number of bytes to pin. len xd Specifies the cross-memory descriptor.

# **Description**

The xmempin kernel service is used to pin pages backing a specified memory region which is defined in either system or user address space. Pinning a memory region prohibits the pager from stealing pages from the pages backing the pinned memory region. Once a memory region is pinned, accessing that region does not result in a page fault until the region is subsequently unpinned.

The cross-memory descriptor must have been filled in correctly prior to the **xmempin** call (for example, by calling the xmattach kernel service).

## **Execution Environment**

The **xmempin** kernel service can be called from the process environment only.

## **Return Values**

Indicates successful completion.

**EFAULT** Indicates that the memory region as specified by the base and len parameters is not within the address

space specified by the xd parameter.

**EINVAL** Indicates that the value of the length parameter is negative or 0. Otherwise, the area of memory

beginning at the byte specified by the base parameter and extending for the number of bytes specified by

the *len* parameter is not defined.

**ENOMEM** Indicates that the xmempin kernel service is unable to pin the region due to insufficient real memory or

because it has exceeded the systemwide pin count.

#### **Related Information**

The **pin** kernel service, **unpin** kernel service, **xmemunpin** kernel service.

Understanding Execution Environments and Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# xmemunpin Kernel Service

# **Purpose**

Unpins the specified address range in user or system memory.

# **Syntax**

#include <sys/types.h> #include <sys/errno.h> #include <sys/uio.h>

```
int xmemunpin ( base, len, xd)
caddr_t base;
int len;
struct xmem *xd;
```

base Specifies the address of the first byte to unpin.

len Indicates the number of bytes to unpin.xd Specifies the cross-memory descriptor.

# **Description**

The **xmemunpin** kernel service unpins a region of memory. When the pin count is 0, the page is not pinned and can be paged out of real memory. Upon finding an unpinned page, the **xmemunpin** kernel service returns the **EINVAL** error code and leaves any remaining pinned pages still pinned.

The **xmemunpin** service should be used where the address space might be in either user or kernel space.

The cross-memory descriptor must have been filled in correctly prior to the **xmempin** call (for example, by calling the **xmattach** kernel service).

### **Execution Environment**

The **xmemunpin** kernel service can be called in the process environment when unpinning data that is in either user space or system space. It can be called in the interrupt environment only when unpinning data that is in system space.

### **Return Values**

0 Indicates successful completion.

**EFAULT** Indicates that the memory region as specified by the base and len parameters is not within the address

specified by the xd parameter.

**EINVAL** Indicates that the value of the length parameter is negative or 0. Otherwise, the area of memory

beginning at the byte specified by the *base* parameter and extending for the number of bytes specified by the *len* parameter is not defined. If neither cause is responsible, an unpinned page was specified.

## **Related Information**

The **pin** kernel service, **unpin** kernel service, **xmempin** kernel service.

Understanding Execution Environments and Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

#### xmemzero Kernel Service

# **Purpose**

Zeros a buffer described by a cross memory descriptor.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

```
int xmemzero ( dp, uaddr, count)
struct xmem * dp;
caddr_t uaddr;
long count;
```

dp The cross memory descriptor.

The address in the buffer to begin zeroing. uaddr count The number of bytes to be zeroed.

# **Description**

The xmemzero kernel service zeros a buffer described by a cross memory descriptor. The page specified must be in memory.

## **Execution Environment**

The **xmemzero** kernel service can be called from a process or an interrupt environment.

### **Return Values**

XMEM\_SUCC Indicates the area in the buffer has been zeroed. XMEM\_FAIL Indicates one of the following errors:

• The descriptor is marked by XMEM\_REMIO.

The descriptor is not marked by XMEM\_PROC and XMEM\_GLOBAL.

• Count < 0.

#### **Related Information**

Memory Kernel Services and Understanding Virtual Memory Manager Interfaces in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### xmemin Kernel Service

# **Purpose**

Performs a cross-memory move by copying data from the specified address space to kernel global memory.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>
int xmemin (uaddr, kaddr, count, dp)
caddr t * uaddr;
caddr t * kaddr;
int count;
struct xmem * dp;
```

## **Parameters**

uaddr Specifies the address in memory specified by a cross-memory descriptor.

kaddr	Specifies the address in kernel memory.
count	Specifies the number of bytes to copy.
dp	Specifies the cross-memory descriptor.

# **Description**

The **xmemin** kernel service performs a cross-memory move. A cross-memory move occurs when data is moved to or from an address space other than the address space that the program is executing in. The xmemin kernel service copies data from the specified address space to kernel global memory.

The **xmemin** kernel service is provided so that kernel processes and interrupt handlers can safely access a buffer within a user process. Calling the xmattach kernel service prepares the user buffer for the cross-memory move.

The **xmemin** kernel service differs from the **copyin** and **copyout** kernel services in that it is used to access a user buffer when not executing under the user process. In contrast, the copyin and copyout kernel services are used only to access a user buffer while executing under the user process.

## **Execution Environment**

The xmemin kernel service can be called from either the process or interrupt environment.

### **Return Values**

XMEM\_SUCC XMEM FAIL

Indicates successful completion.

Indicates one of the following errors:

- The user does not have the appropriate access authority for the user buffer.
- The user buffer is located in an address range that is not valid.
- · The segment containing the user buffer has been deleted.
- · The cross-memory descriptor is not valid.
- · A paging I/O error occurred while the user buffer was being accessed. If the user buffer is not in memory, the **xmemin** kernel service also returns an **XMEM FAIL** error when executing on an interrupt level.

### **Related Information**

The xmattach kernel service, xmdetach kernel service, xmemout kernel service.

Cross Memory Kernel Services and Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# xmemout Kernel Service

# **Purpose**

Performs a cross-memory move by copying data from kernel global memory to a specified address space.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>
int xmemout (kaddr, uaddr, count, dp)
caddr_t * kaddr;
```

```
caddr_t * uaddr;
int count;
struct xmem * dp;
```

kaddr Specifies the address in kernel memory.

uaddr Specifies the address in memory specified by a cross-memory descriptor.

count Specifies the number of bytes to copy. dp Specifies the cross-memory descriptor.

# Description

The xmemout kernel service performs a cross-memory move. A cross-memory move occurs when data is moved to or from an address space other than the address space that the program is executing in. The xmemout kernel service copies data from kernel global memory to the specified address space.

The xmemout kernel service is provided so that kernel processes and interrupt handlers can safely access a buffer within a user process. Calling the xmattach kernel service prepares the user buffer for the cross-memory move.

The **xmemout** kernel service differs from the **copyin** and **copyout** kernel services in that it is used to access a user buffer when not executing under the user process. In contrast, the copyin and copyout kernel services are only used to access a user buffer while executing under the user process.

## **Execution Environment**

The **xmemout** kernel service can be called from either the process or interrupt environment.

### **Return Values**

XMEM\_SUCC **XMEM FAIL** 

Indicates successful completion.

Indicates one of the following errors:

- · The user does not have the appropriate access authority for the user buffer.
- · The user buffer is located in an address range that is not valid.
- · The segment containing the user buffer has been deleted.
- · The cross-memory descriptor is not valid.
- · A paging I/O error occurred while the user buffer was being accessed. If the user buffer is not in memory, the xmemout service also returns an XMEM FAIL error when executing on an interrupt level.

#### **Related Information**

The **xmattach** kernel service, **xmdetach** kernel service, **xmemin** kernel service.

Cross Memory Kernel Services and Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# xmempsize Kernel Service

# **Purpose**

Reports the page size being used for a specified address range on the 64-bit kernel.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>
long long xmempsize (dp, uaddr, count)
struct xmem * dp;
void * uaddr;
size t count;
```

# Description

The xmempsize kernel service returns the size, in bytes, of the virtual memory pages contained in the memory range starting at uaddr and continuing for count number of bytes. If the memory range consists of virtual memory pages of different sizes, the size of the smallest pages contained in the range is returned.

The cross-memory descriptor, dp, must have been previously initialized to describe the buffer containing the specified range of memory. The xmattach() kernel service prepares a buffer and cross-memory descriptor for use with the xmempsize() kernel service.

## **Parameters**

dp Specifies the cross-memory descriptor.

Specifies the starting address of the memory range. uaddr

count Specifies the number of bytes.

### **Execution Environment**

The **xmempsize** kernel service can be called from either the process or interrupt environment.

The **xmempsize** kernel service is only supported on the 64-bit kernel.

### **Return Values**

On successful completion, the xmempsize() kernel service returns a page size in bytes.

Otherwise, the xmempsize() kernel service returns XMEM\_FAIL.

### **Related Information**

The xmattach kernel service.

Cross Memory Kernel Services and Memory Kernel Services in AIX Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### xmfree Kernel Service

# **Purpose**

Frees allocated memory.

# **Syntax**

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/malloc.h>
```

```
int xmfree ( ptr, heap)
caddr t ptr;
caddr_t heap;
```

ptr Specifies the address of the area in memory to free.

heap Specifies the address of the heap from which the memory was allocated.

# **Description**

The **xmfree** kernel service frees the area of memory pointed to by the *ptr* parameter in the heap specified by the heap parameter. This area of memory must be allocated with the xmalloc kernel service. In addition, the ptr pointer must be the pointer returned from the corresponding xmalloc call.

For example, the **xmfree** (ptr, **kernel heap**) kernel service frees the area in the kernel heap allocated by ptr=xmalloc (size, align, kernel heap).

A kernel extension must explicitly free any memory it allocates. If it does not, eventually subsequent allocations are unsuccessful. Pinned memory must also be unpinned before it is freed if allocated from the kernel\_heap. The kernel does not keep track of which kernel extension owns various allocated areas in the heap. Therefore, the kernel never automatically frees these allocated areas on process termination or device close.

An additional interface to the **xmfree** kernel service is provided. The **free** (ptr) is equivalent to **xmfree** (ptr, kernel\_heap).

## **Execution Environment**

The xmfree kernel service can be called from the process environment only.

#### Return Values

- Indicates successful completion.
- -1 Indicates one of the following errors:
  - The area to be freed was not allocated with the xmalloc kernel service.
  - · The heap was not initialized for memory allocation.

### **Related Information**

The **xmalloc** kernel service.

Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# xmgethkeyset Kernel Service

# **Purpose**

Retrieves the hardware keyset associated with a cross-memory descriptor.

# **Syntax**

```
#include <sys/types.h>
#include <sys/kerrno.h>
#include <sys/xmem.h>
#include <sys/skeys.h>
kerrno_t xmgethkeyset (dp, keyset, flags)
struct xmem * dp;
hkeyset_t * hkeyset;
long flags;
```

#### **Parameters**

Specifies a valid cross-memory descriptor.

hkeyset Pointer to returned hardware keyset associated with the cross-memory descriptor.

flags Must be set to zero.

# **Description**

The xmgethkeyset() kernel service can be used to obtain the keyset associated with a cross-memory descriptor.

Kernel-key protection can be enforced on memory regions described by a cross-memory descriptor. The enforcement is done during normal access checking performed by cross-memory services, such as xmemdma() service.

### **Execution Environment**

The xmgethkeyset kernel service can be called from the process or interrupt environment.

### **Return Values**

Successful. **EINVAL XMGETHKEYSET** Invalid parameter.

### **Related Information**

The xmsethkeyset, xmattach kernel services.

# xmsethkeyset Kernel Service

# **Purpose**

Alters hardware keyset associated with a cross-memory descriptor.

# **Syntax**

```
#include <sys/types.h>
#include <sys/kerrno.h>
#include <sys/xmem.h>
#include <sys/skeys.h>
kerrno_t xmsethkeyset (dp, hkeyset, flags)
struct xmem * dp;
hkeyset_t hkeyset;
long flags;
```

dр Specifies a valid cross-memory descriptor.

hkeyset Hardware keyset to assign to the cross-memory descriptor.

flags Must be set to zero.

# **Description**

The xmsethkeyset() kernel service can be used to modify the keyset associated with a cross-memory descriptor.

Kernel-key protection can be enforced on memory regions described by a cross-memory descriptor. The enforcement is done during normal access checking performed by cross-memory services, such as the xmemdma() service.

### **Execution Environment**

The xmsethkeyset kernel service can be called from the process environment only.

## **Return Values**

Successful.

**EINVAL\_XMSETHKEYSET** Invalid parameter or execution environment.

## **Related Information**

The xmgethkeyset, xmattach kernel services.

# **Chapter 2. Device Driver Operations**

# **Standard Parameters to Device Driver Entry Points**

# **Purpose**

Provides a description of standard device driver entry points parameters.

# **Description**

There are three parameters passed to device driver entry points that always have the same meanings: the *devno* parameter, the *chan* parameter, and the *ext* parameter.

### The devno Parameter

This value, defined to be of type **dev\_t**, specifies the device or subdevice to which the operation is directed. For convenience and portability, the **/usr/include/sys/sysmacros.h** file defines the following macros for manipulating device numbers:

Macro Descriptionf

major(devno)Returns the major device number.minor(devno)Returns the minor device number.

makedev(maj, min). Constructs a composite device number in the format of devno from the major and

minor device numbers given.

### The chan Parameter

This value, defined to be of type **chan\_t**, is the channel ID for a multiplexed device driver. If the device driver is not multiplexed, *chan* has the value of 0. If the driver is multiplexed, then the *chan* parameter is the **chan\_t** value returned from the device driver's **ddmpx** routine.

### The ext Parameter

The *ext* parameter, or extension parameter, is defined to be of type **int**. It is meaningful only with calls to such extended subroutines as the **openx**, **readx**, **writex**, and **ioctlx** subroutines. These subroutines allow applications to pass an extra, device-specific parameter to the device driver. This parameter is then passed to the **ddopen**, **ddread**, **ddwrite**, and **ddioctl** device driver entry points as the *ext* parameter. If the application uses one of the non-extended subroutines (for example, the **read** instead of the **readx** subroutine), then the *ext* parameter has a value of 0.

**Note:** Using the *ext* parameter is highly discouraged because doing so makes an application program less portable to other operating systems.

#### **Related Information**

The **ddioctl** device driver entry point, **ddmpx** device driver entry point, **ddopen** device driver entry point, **ddwrite** device driver entry point.

The close subroutine, ioctl subroutine, lseek subroutine, open subroutine, read subroutine, write subroutine.

# **buf Structure**

# **Purpose**

Describes buffering data transfers between a program and the peripheral device

## Introduction to Kernel Buffers

For block devices, kernel buffers are used to buffer data transfers between a program and the peripheral device. These buffers are allocated in blocks of 4096 bytes. At any given time, each memory block is a member of one of two linked lists that the device driver and the kernel maintain:

List	Description
Available buffer queue (avlist)	A list of all buffers available for use. These buffers do not contain data waiting to be transferred to or from a device.
Busy buffer queue (blist)	A list of all buffers that contain data waiting to be transferred to or from a device.

Each buffer has an associated buffer header called the buf structure pointing to it. Each buffer header has several parts:

- Information about the block
- · Flags to show status information
- · Busy list forward and backward pointers
- · Available list forward and backward pointers

The device driver maintains the av\_forw and av\_back pointers (for the available blocks), while the kernel maintains the b\_forw and b\_back pointers (for the busy blocks).

## buf Structure Variables for Block I/O

The buf structure, which is defined in the /usr/include/sys/buf.h file, includes the following fields:

b\_flags

Flag bits. The value of this field is constructed by logically ORing 0 or more of the following values:

#### **B\_WRITE**

This operation is a write operation.

#### **B READ**

This operation is a read data operation, rather than write.

#### **B DONE**

 $\ensuremath{\mathsf{I/O}}$  on the buffer has been done, so the buffer information is more current than other versions.

#### **B ERROR**

A transfer error has occurred and the transaction has aborted.

#### **B BUSY**

The block is not on the free list.

### **B\_INFLIGHT**

This I/O request has been sent to the physical device driver for processing.

#### **B\_AGE**

The data is not likely to be reused soon, so prefer this buffer for reuse. This flag suggests that the buffer goes at the head of the free list rather than at the end.

#### **B\_ASYNC**

Asynchronous I/O is being performed on this block. When I/O is done, release the block.

#### **B\_DELWRI**

The contents of this buffer still need to be written out before the buffer can be reused, even though this block may be on the free list. This is used by the **write** subroutine when the system expects another write to the same block to occur soon.

#### **B\_NOHIDE**

Indicates that the data page should not be hidden during direct memory access (DMA) transfer.

#### **B SETMOD**

Allows an enhanced I/O file system to cause a page to be considered modified.

#### **B STALE**

The data conflicts with the data on disk because of an I/O error.

#### **B XREADONLY**

Indicates a read-only page in the external pager buffer list.

#### **B MORE DONE**

When set, indicates to the receiver of this **buf** structure that more structures are queued in the **IODONE** level. This permits device drivers to handle all completed requests before processing any new requests.

#### **B SPLIT**

When set, indicates that the transfer can begin anywhere within the data buffer.

b\_forw The forward busy block pointer.
b back The backward busy block pointer.

av\_forw The forward pointer for a driver request queue.
av\_back The backward pointer for a driver request queue.

b\_iodone Anyone calling the strategy routine must set this field to point to their I/O done routine. This

routine is called on the **INTIODONE** interrupt level when I/O is complete.

b\_devb bcountThe major and minor device number.The byte count for the data transfer.

The memory address of the data buffer. b un.b addr

b blkno The block number on the device.

b resid Amount of data not transferred after error.

b event Anchor for event list.  $b\_xmemd$ Cross-memory descriptor.

### **Related Information**

The **ddstrategy** device driver entry point.

The write subroutine.

The **bufx** structure.

Cross Memory Kernel Services in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## **bufx Structure**

# **Purpose**

Extends the **buf** structure to accommodate new fields as needed for performance and RAS reasons.

# **Description**

The bufx structure is available for use by the 64-bit kernel and 64-bit kernel extensions. The 32-bit kernel and 32-bit kernel extensions only have the option of using the buf structure.

### bufx Structure Variables for Block I/O

The bufx structure, which is defined in the /usr/include/sys/buf.h file, includes the following fields:

b flags

Flag bits. The value of this field is constructed by the logical OR operation with 0 or more of the following values:

#### **B\_WRITE**

This operation is a write operation.

#### **B\_READ**

This operation is a read data operation.

#### **B DONE**

I/O on the buffer is done, so the buffer information is more current than other versions.

#### **B ERROR**

A transfer error occurred and the transaction aborted.

#### **B\_BUSY**

The block is not on the free list.

#### **B\_INFLIGHT**

This I/O request was sent to the physical device driver for processing.

#### **B AGE**

The data is not likely to be reused soon, so prefer this buffer for reuse. This flag suggests that the buffer goes at the head of the free list rather than at the end.

#### **B ASYNC**

Asynchronous I/O is being performed on this block. When I/O is done, release the block.

#### **B** DELWRI

The contents of this buffer still need to be written out before the buffer can be reused, even though this block may be on the free list. This is used by the **write** subroutine when the system expects another write to the same block to occur soon.

#### **B NOHIDE**

Indicates that the data page should not be hidden during direct memory access (DMA) transfer.

#### **B STALE**

The data conflicts with the data on disk because of an I/O error.

#### **B\_MORE\_DONE**

When set, indicates to the receiver of this **bufx** structure that more structures are queued in the **IODONE** level. This permits device drivers to handle all completed requests before processing any new requests.

#### **B\_SPLIT**

When set, indicates that the transfer can begin anywhere within the data buffer.

#### **B** BUFX

A buffer is identified as an extended **buf** structure if all of the following conditions are met:

- B\_BUFX bit is set in the b\_flags field.
- The pointer obtained by recombining the bx\_refptrtop field and the bx\_refptrbot field points to the beginning of the structure.
- The bx\_eyecatcher field, which identifies whether the buf structure is extended or not, is equal to the ASCII string "bufx".

#### **B BUFX INITIAL**

When set, indicates that the **buf** is extended.

b\_forw The forward busy block pointer.
b back The backward busy block pointer.

av forw The forward pointer for a driver request queue.

av back The backward pointer for a driver request queue.

b iodone Anyone calling the strategy routine must set this field to point to their I/O done routine. This

routine is called on the INTIODONE interrupt level when I/O is complete.

The major and minor device number. b dev b bcount The byte count for the data transfer. b un.b addr The memory address of the data buffer.

b blkno The block number on the device.

The amount of data not transferred after error. b resid

b event The anchor for event list. The cross-memory descriptor. b xmemd bx refptrtop The top half of the reference pointer. bx refptrbot The bottom half of the reference pointer. bx version The version of the **bufx** structure.

The field contains the string "bufx", allowing for easy identification of the bufx structure in KDB bx eyecatcher

when dumping data and for structure verification in addition to using the BUFX\_VALIDATE

bx flags Bufx flags with a 64-bit field that can be used for bufx-specific flags that are yet to be defined.

bx io priority If the underlying storage devices do not support I/O priority, this value is ignored. The

bx io priority must be either the value of IOPRIORITY UNSET (0) or a value from 1 to 15. Lower I/O priority values are considered to be more important than higher values. For example, a value of 1 is considered the highest priority and a value of 15 is considered the lowest

priority. The value of IOPRIORITY UNSET is defined in the sys/extendio.h file.

If the underlying storage devices do not support I/O cache hints, this value is ignored. The bx\_io\_cache\_hint

> bx io cache hint must be either the value of CH AGE OUT FAST or the value of CH PAGE WRITE (defined in the sys/extendio.h file). These values are mutually exclusive. If CH AGE OUT FAST is set, the I/O buffer can be aged out quickly from the storage device buffer cache. This is useful in the situations where the application is already caching the I/O buffer and redundant caching within the storage layer can be avoided. If CH PAGE WRITE is set, the I/O buffer is written only to

the storage device cache and not to the disk.

### **Related Information**

The **buf** structure.

### **Character Lists Structure**

Character device drivers, and other character-oriented support that can perform character-at-a-time I/O, can be implemented by using a common set of services and data buffers to handle characters in the form of character lists. A character list is a list or queue of characters. Some routines put characters in a list, and others remove the characters from the list.

Character lists, known as clists, contain a clist header and a chain of one or more data buffers known as character blocks. Putting characters on a queue allocates space (character blocks) from the common pool and links the character block into the data structure defining the character queue. Obtaining characters from a gueue returns the corresponding space back to the pool.

A character list can be used to communicate between a character device driver top and bottom half. The clist header and the character blocks that are used by these routines must be pinned in memory, since they are accessed in the interrupt environment.

Users of the character list services must register (typically in the device driver **ddopen** routine) the number of character blocks to be used at any one time. This allows the kernel to manage the number of pinned character blocks in the character block pool. Similarly, when usage terminates (for example, when the device driver is closed), the using routine should remove its registration of character blocks. The pincf kernel service provides registration for character block usage.

The kernel provides four services for obtaining characters or character blocks from a character list: the getc, getcb, getcbp, and getcx kernel services. There are also four services that add characters or character blocks to character lists: the putc, putcb, putcbp, and putcx kernel services. The getcf kernel services allocates a free character block while the putcf kernel service returns a character block to the free list. Additionally, the putcfl kernel service returns a list of character buffers to the free list. The waitcfree kernel service determines if any character blocks are on the free list, and waits for one if none are available.

## Using a Character List

For each character list you use, you must allocate a clist header structure. This clist structure is defined in the /usr/include/sys/cblock.h file.

You do not need to be concerned with maintaining the fields in the clist header, as the character list services do this for you. However, you should initialize the c cc count field to 0, and both character block pointers (c cf and c c1) to null before using the clist header for the first time. The clist structure defines these fields.

Each buffer in the character list is a cblock structure, which is also defined in the /usr/include/sys/ cblock.h file.

A character block data area does not need to be completely filled with characters. The c first and c last fields are zero-based offsets within the c data array, which actually contains the data.

Only a limited amount of memory is available for character buffers. All character drivers share this pool of buffers. Therefore, you must limit the number of characters in your character list to a few hundred. When the device is closed, the device driver should make certain all of its character lists are flushed so the buffers are returned to the list of free buffers.

### **Related Information**

The getc kernel service, getcb kernel service, getcbp kernel service, getcf kernel service, getcx kernel service, pincf kernel service, putc kernel service, putcb kernel service, putcb kernel service, putcf kernel service, putcfl kernel service, putcx kernel service, waitcfree kernel service.

Programming in the Kernel Environment Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

### uio Structure

## Purpose

Describes a memory buffer to be used in a data transfer.

#### Introduction

The user I/O or **uio** structure is a data structure describing a memory buffer to be used in a data transfer. The **uio** structure is most commonly used in the read and write interfaces to device drivers supporting character or raw I/O. It is also useful in other instances in which an input or output buffer can exist in different kinds of address spaces, and in which the buffer is not contiguous in virtual memory.

The **uio** structure is defined in the **/usr/include/sys/uio.h** file.

The **uio** structure describes a buffer that is not contiguous in virtual memory. It also indicates the address space in which the buffer is defined. When used in the character device read and write interface, it also contains the device open-mode flags, along with the device read/write offset.

The kernel provides services that access data using a **uio** structure. The **ureadc**, **uwritec**, **uiomove**, and uphysio kernel services all perform data transfers into or out of a data buffer described by a uio structure. The **ureadc** kernel service writes a character into the buffer described by the **uio** structure. The **uwritec** kernel service reads a character from the buffer. These two services have names opposite from what you would expect, since they are named for the user action initiating the operation. A read on the part of the user thus results in a device driver writing to the buffer, while a write results in a driver reading from the buffer.

The **uiomove** kernel service copies data to or from a buffer described by a **uio** structure from or to a buffer in the system address space. The uphysio kernel service is used primarily by block device drivers providing raw I/O support. The uphysio kernel service converts the character read or write request into a block read or write request and sends it to the **ddstrategy** routine.

The buffer described by the **uio** structure can consist of multiple noncontiguous areas of virtual memory of different lengths. This is achieved by describing the data buffer with an array of elements, each of which consists of a virtual memory address and a byte length. Each element is defined as an iovec element. The uio structure also contains a field specifying the total number of bytes in the data buffer described by the structure.

Another field in the uio structure describes the address space of the data buffer, which can either be system space, user space, or cross-memory space. If the address space is defined as cross memory, an additional array of cross-memory descriptors is specified in the uio structure to match the array of iovec elements.

The **uio** structure also contains a byte offset (uio offset). This field is a 64 bit integer (offset t); it allows the file system to send I/O requests to a device driver's read & write entry points which have logical offsets beyond 2 gigabytes. Device drivers must use care not to cause a loss of significance by assigning the offset to a 32 bit variable or using it in calculations that overflow a 32 bit variable.

The called routine (device driver) is permitted to modify fields in the uio and iovec structures as the data transfer progresses. The final uio resid count is in fact used to determine how much data was transferred. Therefore this count must be decremented, with each operation, by the number of bytes actually copied.

The **uio** structure contains the following fields:

Field	Description
uio_iov	A pointer to an array of iovec structures describing the user buffer for the data transfer.
uio_xmem	A pointer to an array of <b>xmem</b> structures containing the cross-memory descriptors for the <b>iovec</b> array.
uio_iovcnt	The number of yet-to-be-processed <b>iovec</b> structures in the array pointed to by the uio_iov pointer. The count must be at least 1. If the count is greater than 1, then a <i>scatter-gather</i> of the data is to be performed into or out of the areas described by the <b>iovec</b> structures.
uio_iovdcnt	The number of already processed iovec structures in the iovec array.
uio_offset	The file offset established by a previous <b>Iseek</b> , <b>Ilseek</b> subroutine call. Most character devices ignore this variable, but some, such as the <b>/dev/mem</b> pseudo-device, use and maintain it.
uio_segflg	A flag indicating the type of buffer being described by the <b>uio</b> structure. This flag typically describes whether the data area is in user or kernel space or is in cross-memory. Refer to the <b>/usr/include/sys/uio.h</b> file for a description of the possible values of this flag and their meanings.

Field	Description
uio_fmode	The value of the file mode that was specified on opening the file or modified by the <b>fcntl</b> subroutine. This flag describes the file control parameters. The <b>/usr/include/sys/fcntl.h</b> file
	contains specific values for this flag.
uio_resid	The byte count for the data transfer. It must not exceed the sum of all the <code>iov_len</code> values in the array of <b>iovec</b> structures. Initially, this field contains the total byte count, and when the operation completes, the value must be decremented by the actual number of bytes

The iovec structure contains the starting address and length of a contiguous data area to be used in a data transfer. The iovec structure is the element type in an array pointed to by the uio iov field in the uio structure. This array can contain any number of iovec structures, each of which describes a single unit of contiguous storage. Taken together, these units represent the total area into which, or from which, data is

to be transferred. The uio iovent field gives the number of **iovec** structures in the array.

The **iovec** structure contains the following fields:

transferred.

Field	Description
iov_base	A variable in the <b>iovec</b> structure containing the base address of the contiguous data area in the
	address space specified by the uio_segflag field. The length of the contiguous data area is specified by the iov_len field.
iov_len	A variable in the <b>iovec</b> structure containing the byte length of the data area starting at the address given in the <b>iov_base</b> variable.

# **ddclose Device Driver Entry Point**

# **Purpose**

Closes a previously open device instance.

# **Syntax**

```
#include <sys/device.h>
#include <sys/types.h>
int ddclose ( devno, chan)
dev_t devno;
chan_t chan;
```

### **Parameters**

devno Specifies the major and minor device numbers of the device instance to close.

chan Specifies the channel number.

## **Description**

The **ddclose** entry point is called when a previously opened device instance is closed by the **close** subroutine or fp\_close kernel service. The kernel calls the routine under different circumstances for non-multiplexed and multiplexed device drivers.

For non-multiplexed device drivers, the kernel calls the **ddclose** routine when the last process having the device instance open closes it. This causes the q-node reference count to be decremented to 0 and the g-node to be deallocated.

For multiplexed device drivers, the **ddclose** routine is called for each close associated with an explicit open. In other words, the device driver's ddclose routine is invoked once for each time its ddopen routine was invoked for the channel.

In some instances, data buffers should be written to the device before returning from the **ddclose** routine. These are buffers containing data to be written to the device that have been queued by the device driver but not yet written.

Non-multiplexed device drivers should reset the associated device to an idle state and change the device driver device state to closed. This can involve calling the **fp close** kernel service to issue a close to an associated open device handler for the device. Returning the device to an idle state prevents the device from generating any more interrupt or direct memory access (DMA) requests. DMA channels and interrupt levels allocated for this device should be freed, until the device is re-opened, to release critical system resources that this device uses.

Multiplexed device drivers should provide the same device quiescing, but not in the **ddclose** routine. Returning the device to the idle state and freeing its resources should be delayed until the ddmpx routine is called to deallocate the last channel allocated on the device.

In all cases, the device instance is considered closed once the **ddclose** routine has returned to the caller, even if a nonzero return code is returned.

### **Execution Environment**

The **ddclose** routine is executed only in the process environment. It should provide the required serialization of its data structures by using the locking kernel services in conjunction with a private lock word defined in the driver.

### **Return Values**

The **ddclose** entry point can indicate an error condition to the user-mode application program by returning a nonzero return code. This causes the subroutine call to return a value of -1. It also makes the return code available to the user-mode application in the errno global variable. The return code used should be one of the values defined in the /usr/include/sys/errno.h file.

The device is always considered closed even if a nonzero return code is returned.

When applicable, the return values defined in the POSIX 1003.1 standard for the close subroutine should be used.

### **Related Information**

The **ddopen** device driver entry point.

The fp close kernel service, i clear kernel service, i disable kernel service.

The **close** subroutine, **open** subroutine.

Device Driver Kernel Extension Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

Programming in the Kernel Environment Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## ddconfig Device Driver Entry Point

## **Purpose**

Performs configuration functions for a device driver.

# **Syntax**

```
#include <sys/device.h>
#include <sys/types.h>
int ddconfig ( devno, cmd, uiop)
dev_t devno;
int cmd;
struct uio *uiop;
```

### **Parameters**

devno Specifies the major and minor device numbers.

Specifies the function to be performed by the **ddconfig** routine. cmd

uiop Points to a uio structure describing the relevant data area for configuration information.

# **Description**

The **ddconfig** entry point is used to configure a device driver. It can be called to do the following tasks:

- · Initialize the device driver.
- · Terminate the device driver.
- · Request configuration data for the supported device.
- Perform other device-specific configuration functions.

The **ddconfig** routine is called by the device's Configure, Unconfigure, or Change method. Typically, it is called once for each device number (major and minor) to be supported. This is, however, device-dependent. The specific device method and ddconfig routine determines the number of times it is called.

The **ddconfig** routine can also provide additional device-specific functions relating to configuration, such as returning device vital product data (VPD). The **ddconfig** routine is usually invoked through the sysconfig subroutine by the device-specific Configure method.

Device drivers and their methods typically support these values for the *cmd* parameter:

### Value CFG\_INIT

#### Description

Initializes the device driver and internal data areas. This typically involves the minor number specified by the devno parameter, for validity. The device driver's ddconfig routine also installs the device driver's entry points in the device switch table, if this was the first time called (for the specified major number). This can be accomplished by using the devswadd kernel service along with a devsw structure to add the device driver's entry points to the device switch table for the major device number supplied in the devno parameter.

The CFG INIT command parameter should also copy the device-dependent information (found in the device-dependent structure provided by the caller) into a static or dynamically allocated save area for the specified device. This information should be used when the ddopen routine is later called.

The device-dependent structure's address and length are described in the **uio** structure pointed to by the *uiop* parameter. The **uiomove** kernel service can be used to copy the device-dependent structure into the device driver's data area.

When the ddopen routine is called, the device driver passes device-dependent information to the routines or other device drivers providing the device handler role in order to initialize the device. The delay in initializing the device until the ddopen call is received is useful in order to delay the use of valuable system resources (such as DMA channels and interrupt levels) until the device is actually needed.

#### CFG\_TERM

Terminates the device driver associated with the specified device number, as represented by the devno parameter. The ddconfig routine determines if any opens are outstanding on the specified devno parameter. If none are, the CFG TERM command processing marks the device as terminated, disallowing any subsequent opens to the device. All dynamically allocated data areas associated with the specified device number should be freed.

If this termination removes the last minor number supported by the device driver from use, the devswdel kernel service should be called to remove the device driver's entry points from the device switch table for the specified devno parameter.

If opens are outstanding on the specified device, the terminate operation is rejected with an appropriate error code returned. The Unconfigure method can subsequently unload the device driver if all uses of it have been terminated.

To determine if all the uses of the device driver have been terminated, a device method can make a sysconfig subroutine call. By using the sysconfig SYS\_QDVSW operation, the device method can learn whether or not the device driver has removed itself from the device switch table. Queries device-specific vital product data (VPD).

### CFG\_QVPD

For this function, the calling routine sets up a uio structure pointed at by the uiop parameter to the ddconfig routine. This uio structure defines an area in the caller's storage in which the ddconfig routine is to write the VPD. The uiomove kernel service can be used to provide the data copy

operation.

The data area pointed at by the *uiop* parameter has two different purposes, depending on the *cmd* function. If the CFG\_INIT command has been requested, the uiop structure describes the location and length of the device-dependent data structure (DDS) from which to read the information. If the CFG QVPD command has been requested, the uiop structure describes the area in which to write vital product data information. The content and format of this information is established by the specific device methods in conjunction with the device driver.

The **uiomove** kernel service can be used to facilitate copying information into or out of this data area. The format of the uio structure is defined in the /usr/include/sys/uio.h file and described further in the uio structure.

#### **Execution Environment**

The **ddconfig** routine and its operations are called in the process environment only.

### **Return Values**

The **ddconfig** routine sets the return code to 0 if no errors are detected for the operation specified. If an error is to be returned to the caller, a nonzero return code should be provided. The return code used should be one of the values defined in the /usr/include/sys/errno.h file.

If this routine was invoked by a sysconfig subroutine call, the return code is passed to its caller (typically a device method). It is passed by presenting the error code in the errno global variable and providing a -1 return code to the subroutine.

### **Related Information**

The **sysconfig** subroutine.

The **ddopen** device driver entry point.

The devswadd kernel service, devswdel kernel service, uiomove kernel service.

## dddump Device Driver Entry Point

## **Purpose**

Writes system dump data to a device.

# **Syntax**

```
#include <sys/device.h>
int dddump (devno, uiop, cmd, arg, chan, ext)
dev t devno;
struct uio * uiop;
int cmd, arg;
chan_t chan;
int ext;
```

### **Parameters**

devno	Specifies the major and minor device numbers.	
uiop	Points to the <b>uio</b> structure describing the data area or areas to be dumped.	
cmd	The parameter from the kernel dump function that specifies the operation to be performed.	
arg	The parameter from the caller that specifies the address of a parameter block associated with the kernel	
	dump command.	
chan	Specifies the channel number.	
ext	Specifies the extension parameter.	

The kernel dump routine calls the **dddump** entry point to set up and send dump requests to the device. The **dddump** routine is optional for a device driver. It is required only when the device driver supports a device as a target for a possible kernel dump.

If this is the case, it is important that the system state change as little as possible when performing the dump. As a result, the **dddump** routine should use the minimal amount of services in writing the dump data to the device.

The *cmd* parameter can specify any of the following dump commands:

### **Dump Command DUMPINIT**

#### Description

Initialization a device in preparation for supporting a system dump. The specified device instance must have previously been opened. The arg parameter points to a dumpio\_stat structure, defined in /usr/include/sys/dump.h. This is used for returning device-specific status in case of

The **dddump** routine should pin all code and data that the device driver uses to support dump writing. This is required to prevent a page fault when actually performing a write of the dump data. (Pinned code should include the **dddump** routine.) The **pin** or **pincode** kernel service can be used for this purpose.

#### **DUMPQUERY**

Determines the maximum and minimum number of bytes that can be transferred to the device in one **DUMPWRITE** command. For network dumps, the address of the write routine used in transferring dump data to the network dump device is also sent. The uiop parameter is not used and is null for this command. The arg parameter is a pointer to a dmp\_query structure, as defined in the /usr/include/sys/dump.h file.

The **dmp\_query** structure contains the following fields:

min tsize

Minimum transfer size (in bytes).

max tsize

Maximum transfer size (in bytes).

dumpwrite

Address of the write routine.

The **DUMPQUERY** command returns the data transfer size information in the **dmp query** structure pointed to by the arg parameter. The kernel dump function then uses a buffer between the minimum and maximum transfer sizes (inclusively) when writing dump data.

If the buffer is not the size found in the max tsize field, then its size must be a multiple of the value in the min tsize field. The min tsize field and the max tsize field can specify the same value.

#### **DUMPSTART**

Suspends current device activity and provide whatever setup of the device is needed before receiving a **DUMPWRITE** command. The arg parameter points to a **dumpio\_stat** structure, defined in /usr/include/sys/dump.h. This is used for returning device-specific status in case of an error.

#### **DUMPWRITE**

Writes dump data to the target device. The **uio** structure pointed to by the *uiop* parameter specifies the data area or areas to be written to the device and the starting device offset. The arg parameter points to a dumpio stat structure, defined in /usr/include/sys/dump.h. This is used for returning device-specific status in case of an error. Code for the DUMPWRITE command should minimize its reliance on system services, process dispatching, and such interrupt services as the **INTIODONE** interrupt priority or device hardware interrupts.

Note: The DUMPWRITE command must never cause a page fault. This is ensured on the part of the caller, since the data areas to be dumped have been determined to be in memory. The device driver must ensure that all of its code, data and stack accesses are to pinned memory during its **DUMPINIT** command processing.

#### **DUMPEND**

Indicates that the kernel dump has been completed. Any cleanup of the device state should be done at this time.

**Dump Command** 

Description

**DUMPTERM** 

Indicates that the specified device is no longer a selected dump target device. If no other devices supported by this dddump routine have a DUMPINIT command outstanding, the DUMPTERM code should unpin any resources pinned when it received the **DUMPINIT** command. (The unpin kernel service is available for unpinning memory.) The DUMPTERM command is received before

the device is closed.

**DUMPREAD** 

Receives the acknowledgment packet for previous **DUMPWRITE** operations to a communications device driver. If the device driver receives the acknowledgment within the specified time, it returns a 0 and the response data is returned to the kernel dump function in the *uiop* parameter. If the device driver does not receive the acknowledgment within the specified time, it returns a value of ETIMEDOUT.

The arg parameter contains a timeout value in milliseconds.

### **Execution Environment**

The **DUMPINIT dddump** operation is called in the process environment only. The **DUMPQUERY**, DUMPSTART, DUMPWRITE, DUMPEND, and DUMPTERM dddump operations can be called in both the process environment and interrupt environment.

### **Return Values**

The **dddump** entry point indicates an error condition to the caller by returning a nonzero return code.

### **Related Information**

The devdump kernel service, dmp\_add kernel service, dmp\_del kernel service, pin kernel service, pincode kernel service, unpin kernel service.

The **uio** structure.

Device Driver Kernel Extension Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

Programming in the Kernel Environment Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# ddioctl Device Driver Entry Point

# **Purpose**

Performs the special I/O operations requested in an ioctl or ioctlx subroutine call.

# **Syntax**

```
#include <sys/device.h>
int ddioctl (devno, cmd, arg, devflag, chan, ext)
dev t devno;
int cmd;
void *arg;
ulong devflag;
chan t chan;
int ext;
```

When a program issues an ioctl or ioctlx subroutine call, the kernel calls the ddioctl routine of the specified device driver. The ddioctl routine is responsible for performing whatever functions are requested. In addition, it must return whatever control information has been specified by the original caller of the ioctl subroutine. The *cmd* parameter contains the name of the operation to be performed.

Most ioctl operations depend on the specific device involved. However, all ioctl routines must respond to the following command:

#### **IOCINFO**

Returns a **devinfo** structure (defined in the /usr/include/sys/devinfo.h file) that describes the device. (Refer to the description of the special file for a particular device in the Application Programming Interface.) Only the first two fields of the data structure need to be returned if the remaining fields of the structure do not apply to the device.

The devflag parameter indicates one of several types of information. It can give conditions in which the device was opened. (These conditions can subsequently be changed by the fcntl subroutine call.) Alternatively, it can tell which of two ways the entry point was invoked:

- · By the file system on behalf of a using application
- Directly by a kernel routine using the fp ioctl kernel service

Thus flags in the devflag parameter have the following definitions, as defined in the /usr/include/sys/ device.h file:

DKERNEL Entry point called by kernel routine using the **fp\_ioctl** service.

DREAD Open for reading. DWRITE Open for writing. DAPPEND Open for appending.

DNDELAY Device open in nonblocking mode.

### **Parameters**

devno Specifies the major and minor device numbers.

cmd The parameter from the **ioctl** subroutine call that specifies the operation to be performed. The parameter from the ioctl subroutine call that specifies an additional argument for the cmd arg

devflag Specifies the device open or file control flags.

chan Specifies the channel number. Specifies the extension parameter. ext

### **Execution Environment**

The **ddioctl** routine is executed only in the process environment. It should provide the required serialization of its data structures by using the locking kernel services in conjunction with a private lock word defined in the driver.

### **Return Values**

The **ddioctl** entry point can indicate an error condition to the user-mode application program by returning a nonzero return code. This causes the ioctl subroutine to return a value of -1 and makes the return code available to the user-mode application in the errno global variable. The error code used should be one of the values defined in the /usr/include/sys/errno.h file.

When applicable, the return values defined in the POSIX 1003.1 standard for the ioctl subroutine should be used.

### **Related Information**

The fp\_ioctl kernel service.

The **fcntl** subroutine, **ioctl** or **ioctlx** subroutine, **open** subroutine.

## ddmpx Device Driver Entry Point

## **Purpose**

Allocates or deallocates a channel for a multiplexed device driver.

## **Syntax**

```
#include <sys/device.h>
#include <sys/types.h>
int ddmpx ( devno, chanp, channame)
dev t devno:
chan t *chanp;
char *channame;
```

### **Parameters**

devno Specifies the major and minor device numbers. Specifies the channel ID, passed by reference. chanp

Points to the path name extension for the channel to be allocated. channame

# **Description**

Only multiplexed character class device drivers can provide the **ddmpx** routine, and every multiplexed driver must do so. The **ddmpx** routine cannot be provided by block device drivers even when providing raw read/write access.

A multiplexed device driver is a character class device driver that supports the assignment of channels to provide finer access control to a device or virtual subdevice. This type of device driver has the capability to decode special channel-related information appended to the end of the path name of the device's special file. This path name extension is used to identify a logical or virtual subdevice or channel.

When an open or creat subroutine call is issued to a device instance supported by a multiplexed device driver, the kernel calls the device driver's **ddmpx** routine to allocate a channel.

The kernel calls the **ddmpx** routine when a channel is to be allocated or deallocated. Upon allocation, the kernel dynamically creates q-nodes (in-core i-nodes) for channels on a multiplexed device to allow the protection attributes to differ for various channels.

To allocate a channel, the **ddmpx** routine is called with a *channame* pointer to the path name extension. The path name extension starts after the first / (slash) character that follows the special file name in the path name. The **ddmpx** routine should perform the following actions:

- · Parse this path name extension.
- Allocate the corresponding channel.
- Return the channel ID through the chanp parameter.

If no path name extension exists, the channame pointer points to a null character string. In this case, an available channel should be allocated and its channel ID returned through the *chanp* parameter.

If no error is returned from the ddmpx routine, the returned channel ID is used to determine if the channel was already allocated. If already allocated, the g-node for the associated channel has its reference count incremented. If the channel was not already allocated, a new g-node is created for the channel. In either case, the device driver's ddopen routine is called with the channel number assigned by the ddmpx routine. If a nonzero return code is returned by the **ddmpx** routine, the channel is assumed not to have been allocated, and the device driver's **ddopen** routine is not called.

If a close of a channel is requested so that the channel is no longer used (as determined by the channel's g-node reference count going to 0), the kernel calls the **ddmpx** routine. The **ddmpx** routine deallocates the channel after the ddclose routine was called to close the last use of the channel. If a nonzero return code is returned by the **ddclose** routine, the **ddmpx** routine is still called to deallocate the channel. The ddclose routine's return code is saved, to be returned to the caller. If the ddclose routine returned no error, but a nonzero return code was returned by the ddmpx routine, the channel is assumed to be deallocated, although the return code is returned to the caller.

To deallocate a channel, the **ddmpx** routine is called with a null *channame* pointer and the channel ID passed by reference in the chanp parameter. If the channel g-node reference count has gone to 0, the kernel calls the ddmpx routine to deallocate the channel after invoking the ddclose routine to close it. The ddclose routine should not itself deallocate the channel.

### **Execution Environment**

The **ddmpx** routine is called in the process environment only.

#### Return Values

If the allocation or deallocation of a channel is successful, the ddmpx routine should return a return code of 0. If an error occurs on allocation or deallocation, this routine returns a nonzero value.

The return code should conform to the return codes described for the open and close subroutines in the POSIX 1003.1 standard, where applicable. Otherwise, the return code should be one defined in the /usr/include/sys/errno.h file.

### **Related Information**

The **ddclose** device driver entry point, **ddopen** device driver entry point.

Device Driver Kernel Extension Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

Programming in the Kernel Environment Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## ddopen Device Driver Entry Point

# **Purpose**

Prepares a device for reading, writing, or control functions.

## **Syntax**

```
#include <sys/device.h>
int ddopen (devno, devflag, chan, ext)
dev t devno;
ulong devflag;
chan t chan;
int ext;
```

### **Parameters**

devno Indicates major and minor device numbers.

devflaa Specifies open file control flags. Specifies the channel number. chan Specifies the extension parameter. ext

## **Description**

The kernel calls the **ddopen** routine of a device driver when a program issues an **open** or **creat** subroutine call. It can also be called when a system call, kernel process, or other device driver uses the fp opendev or fp open kernel service to use the device.

The **ddopen** routine must first ensure exclusive access to the device, if necessary. Many character devices, such as printers and plotters, should be opened by only one process at a time. The ddopen routine can enforce this by maintaining a static flag variable, which is set to 1 if the device is open and 0 if not.

Each time the **ddopen** routine is called, it checks the value of the flag. If the value is other than 0, the ddopen routine returns with a return code of EBUSY to indicate that the device is already open. Otherwise, the **ddopen** routine sets the flag and returns normally. The **ddclose** entry point later clears the flag when the device is closed.

Since most block devices can be used by several processes at once, a block driver should not try to enforce opening by a single user.

The **ddopen** routine must initialize the device if this is the first open that has occurred. Initialization involves the following steps:

- 1. The **ddopen** routine should allocate the required system resources to the device (such as DMA channels, interrupt levels, and priorities). It should, if necessary, register its device interrupt handler for the interrupt level required to support the target device. (The i\_init and d\_init kernel services are available for initializing these resources.)
- 2. If this device driver is providing the head role for a device and another device driver is providing the handler role, the ddopen routine should use the fp\_opendev kernel service to open the device handler.

**Note:** The **fp opendev** kernel service requires a *devno* parameter to identify which device handler to open. This devno value, taken from the appropriate device dependent structure (DDS), should have been stored in a special save area when this device driver's ddconfig routine was called.

### Flags Defined for the devflag Parameter

The devflag parameter has the following flags, as defined in the /usr/include/sys/device.h file:

DKERNEL Entry point called by kernel routine using the fp\_opendev or fp\_open kernel service.

DREAD Open for reading. DWRITE Open for writing. DAPPEND Open for appending.

DNDELAY Device open in nonblocking mode.

### **Execution Environment**

The ddopen routine is executed only in the process environment. It should provide the required serialization of its data structures by using the locking kernel services in conjunction with a private lock word defined in the driver

### **Return Values**

The **ddopen** entry point can indicate an error condition to the user-mode application program by returning a nonzero return code. Returning a nonzero return code causes the open or creat subroutines to return a value of -1 and makes the return code available to the user-mode application in the errno global variable. The return code used should be one of the values defined in the /usr/include/errno.h file.

If a nonzero return code is returned by the **ddopen** routine, the open request is considered to have failed. No access to the device instance is available to the caller as a result. In addition, for nonmultiplexed drivers, if the failed open was the first open of the device instance, the kernel calls the driver's **ddclose** entry point to allow resources and device driver state to be cleaned up. If the driver was multiplexed, the kernel does not call the **ddclose** entry point on an open failure.

When applicable, the return values defined in the POSIX 1003.1 standard for the open subroutine should be used.

### **Related Information**

The **ddclose** device driver entry point, **ddconfig** device driver entry point.

The fp\_open kernel service, fp\_opendev kernel service, i\_enable kernel service, i\_init kernel service.

The close subroutine, creat subroutine, open subroutine.

Device Driver Kernel Extension Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

Programming in the Kernel Environment Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# ddread Device Driver Entry Point

# **Purpose**

Reads in data from a character device.

# **Syntax**

#include <sys/device.h> #include <sys/types.h>

```
int ddread ( devno, uiop, chan, ext)
dev t devno;
struct uio *uiop;
chan t chan;
int ext;
```

### **Parameters**

devno Specifies the major and minor device numbers.

Points to a uio structure describing the data area or areas in which to be written. aoiu

chan Specifies the channel number. ext Specifies the extension parameter.

## **Description**

When a program issues a read or readx subroutine call or when the fp rwuio kernel service is used, the kernel calls the **ddread** entry point.

This entry point receives a pointer to a uio structure that provides variables used to specify the data transfer operation.

Character device drivers can use the ureadc and uiomove kernel services to transfer data into and out of the user buffer area during a **read** subroutine call. These services receive a pointer to the **uio** structure and update the fields in the structure by the number of bytes transferred. The only fields in the uio structure that cannot be modified by the data transfer are the uio fmode and uio segflg fields.

For most devices, the **ddread** routine sends the request to the device handler and then waits for it to finish. The waiting can be accomplished by calling the e\_sleep kernel service. This service suspends the driver and the process that called it and permits other processes to run until a specified event occurs.

When the I/O operation completes, the device usually issues an interrupt, causing the device driver's interrupt handler to be called. The interrupt handler then calls the e\_wakeup kernel service specifying the awaited event, thus allowing the **ddread** routine to resume.

The uio resid field initially contains the total number of bytes to read from the device. If the device driver supports it, the uio offset field indicates the byte offset on the device from which the read should start.

The uio offset field is a 64 bit integer (offset t); this allows the file system to send I/O requests to a device driver's read & write entry points which have logical offsets beyond 2 gigabytes. Device drivers must use care not to cause a loss of significance by assigning the offset to a 32 bit variable or using it in calculations that overflow a 32 bit variable.

If no error occurs, the uio resid field should be 0 on return from the ddread routine to indicate that all requested bytes were read. If an error occurs, this field should contain the number of bytes remaining to be read when the error occurred.

If a read request starts at a valid device offset but extends past the end of the device's capabilities, no error should be returned. However, the uio resid field should indicate the number of bytes not transferred. If the read starts at the end of the device's capabilities, no error should be returned. However, the uio resid field should not be modified, indicating that no bytes were transferred. If the read starts past the end of the device's capabilities, an ENXIO return code should be returned, without modifying the uio resid field.

When the **ddread** entry point is provided for raw I/O to a block device, this routine usually translates requests into block I/O requests using the **uphysio** kernel service.

### **Execution Environment**

The **ddread** routine is executed only in the process environment. It should provide the required serialization of its data structures by using the locking kernel services in conjunction with a private lock word defined in the driver.

### **Return Values**

The **ddread** entry point can indicate an error condition to the caller by returning a nonzero return code. This causes the subroutine call to return a value of -1. It also makes the return code available to the user-mode program in the **errno** global variable. The error code used should be one of the values defined in the /usr/include/sys/errno.h file.

When applicable, the return values defined in the POSIX 1003.1 standard for the read subroutine should be used.

### **Related Information**

Device Driver Kernel Extension Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

Programming in the Kernel Environment Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# ddrevoke Device Driver Entry Point

## **Purpose**

Ensures that a secure path to a terminal is provided.

# **Syntax**

```
#include <sys/device.h>
#include <sys/types.h>
int ddrevoke ( devno, chan, flag)
dev t devno;
chan_t chan;
int flag;
```

### **Parameters**

devno Specifies the major and minor device numbers.

chan Specifies the channel number. For a multiplexed device driver, a value of -1 in this parameter means

access to all channels is to be revoked.

Currently defined to have the value of 0. (Reserved for future extensions.) flag

The **ddrevoke** entry point can be provided only by character class device drivers. It cannot be provided by block device drivers even when providing raw read/write access. A ddrevoke entry point is required only by device drivers supporting devices in the Trusted Computing Path to a terminal (for example, by the /dev/ Ift and /dev/tty files for the low function terminal and teletype device drivers). The ddrevoke routine is called by the **frevoke** and **revoke** subroutines.

The **ddrevoke** routine revokes access to a specific device or channel (if the device driver is multiplexed). When called, the **ddrevoke** routine should terminate all processes waiting in the device driver while accessing the specified device or channel. It should terminate the processes by sending a SIGKILL signal to all processes currently waiting for a specified device or channel data transfer. The current process is not to be terminated.

If the device driver is multiplexed and the channel ID in the chan parameter has the value -1, all channels are to be revoked.

### **Execution Environment**

The **ddrevoke** routine is called in the process environment only.

#### Return Values

The **ddrevoke** routine should return a value of 0 for successful completion, or a value from the /usr/include/errno.h file on error.

### **Files**

/dev/lft Specifies the path of the LFT special file. /dev/ttv Specifies the path of the tty special file.

### **Related Information**

The frevoke subroutine, revoke subroutine.

# ddselect Device Driver Entry Point

# Purpose

Checks to see if one or more events has occurred on the device.

# **Syntax**

```
#include <sys/device.h>
#include <sys/poll.h>
int ddselect ( devno, events, reventp, chan)
dev t devno;
ushort events;
ushort *reventp;
int chan;
```

### **Parameters**

devno Specifies the major and minor device numbers.

Specifies the events to be checked. events

Returned events pointer. This parameter, passed by reference, is used by the **ddselect** routine to reventp

indicate which of the selected events are true at the time of the call. The returned events location

pointed to by the *reventp* parameter is set to 0 before entering this routine.

chan Specifies the channel number.

# **Description**

The **ddselect** entry point is called when the **select** or **poll** subroutine is used, or when the **fp\_select** kernel service is invoked. It determines whether a specified event or events have occurred on the device.

Only character class device drivers can provide the **ddselect** routine. It cannot be provided by block device drivers even when providing raw read/write access.

### Requests for Information on Events

The events parameter represents possible events to check as flags (bits). There are three basic events defined for the **select** and **poll** subroutines, when applied to devices supporting select or poll operations:

Description **Event** 

Input is present on the device. **POLLIN** POLLOUT The device is capable of output.

POLLPRI An exceptional condition has occurred on the device.

A fourth event flag is used to indicate whether the **ddselect** routine should record this request for later notification of the event using the selnotify kernel service. This flag can be set in the events parameter if the device driver is not required to provide asynchronous notification of the requested events:

**Event** Description

**POLLSYNC** This request is a synchronous request only. The routine need not call the selnotify kernel service for

this request even if the events later occur.

Additional event flags in the events parameter are left for device-specific events on the **poll** subroutine call.

### Select Processing

If one or more events specified in the events parameter are true, the ddselect routine should indicate this by setting the corresponding bits in the reventp parameter. Note that the reventp returned events parameter is passed by reference.

If none of the requested events are true, then the **ddselect** routine sets the returned events parameter to 0. It is passed by reference through the reventp parameter. It also checks the POLLSYNC flag in the events parameter. If this flag is true, the ddselect routine should just return, since the event request was a synchronous request only.

However, if the POLLSYNC flag is false, the ddselect routine must notify the kernel when one or more of the specified events later happen. For this purpose, the routine should set separate internal flags for each event requested in the events parameter.

When any of these events become true, the device driver routine should use the selnotify service to notify the kernel. The corresponding internal flags should then be reset to prevent re-notification of the event.

Sometimes the device can be in a state in which a supported event or events can never be satisfied (such as when a communication line is not operational). In this case, the **ddselect** routine should simply set the corresponding reventp flags to 1. This prevents the select or poll subroutine from waiting indefinitely. As a result however, the caller will not in this case be able to distinguish between satisfied events and unsatisfiable ones. Only when a later request with an NDELAY option fails will the error be detected.

Note: Other device driver routines (such as the ddread, ddwrite routines) may require logic to support select or poll operations.

### **Execution Environment**

The **ddselect** routine is executed only in the process environment. It should provide the required serialization of its data structures by using the locking kernel services in conjunction with a private lock word defined in the driver.

### **Return Values**

The ddselect routine should return with a return code of 0 if the select or poll operation requested is valid for the resource specified. Requested operations are not valid, however, if either of the following is true:

- The device driver does not support a requested event.
- The device is in a state in which poll and select operations are not accepted.

In these cases, the **ddselect** routine should return with a nonzero return code (typically **EINVAL**), and without setting the relevant reventp flags to 1. This causes the poll subroutine to return to the caller with the **POLLERR** flag set in the returned events parameter associated with this resource. The **select** subroutine indicates to the caller that all requested events are true for this resource.

When applicable, the return values defined in the POSIX 1003.1 standard for the select subroutine should be used.

### **Related Information**

The ddread device driver entry point, ddwrite device driver entry point.

The **fp select** kernel service, **selnotify** kernel service.

The **poll** subroutine, **select** subroutine.

Programming in the Kernel Environment Overview and Device Driver Kernel Extension Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# ddstrategy Device Driver Entry Point

# **Purpose**

Performs block-oriented I/O by scheduling a read or write to a block device.

# **Syntax**

void ddstrategy ( bp) struct buf \*bp;

### **Parameter**

bp Points to a **buf** structure describing all information needed to perform the data transfer.

When the kernel needs a block I/O transfer, it calls the **ddstrategy** strategy routine of the device driver for that device. The strategy routine schedules the I/O to the device. This typically requires the following actions:

- The request or requests must be added on the list of I/O requests that need to be processed by the device.
- · If the request list was empty before the preceding additions, the device's start I/O routine must be called.

### **Required Processing**

The **ddstrategy** routine can receive a single request with multiple **buf** structures. However, it is not required to process requests in any specific order.

The strategy routine can be passed a list of operations to perform. The av forw field in the buf header describes this null-terminated list of buf headers. This list is not doubly linked: the av back field is undefined.

Block device drivers must be able to perform multiple block transfers. If the device cannot do multiple block transfers, or can only do multiple block transfers under certain conditions, then the device driver must transfer the data with more than one device operation.

### Kernel Buffers and Using the buf Structure

An area of memory is set aside within the kernel memory space for buffering data transfers between a program and the peripheral device. Each kernel buffer has a header, the buf structure, which contains all necessary information for performing the data transfer. The **ddstrategy** routine is responsible for updating fields in this header as part of the transfer.

The caller of the strategy routine should set the b iodone field to point to the caller's I/O done routine. When an I/O operation is complete, the device driver calls the **iodone** kernel service, which then calls the I/O done routine specified in the b iodone field. The iodone kernel service makes this call from the **INTIODONE** interrupt level.

The value of the b flags field is constructed by logically ORing zero or more possible b flags field flag values.

Attention: Do not modify any of the following fields of the buf structure passed to the ddstrategy entry point: the b forw, b back, b dev, b un, or b blkno field. Modifying these fields can cause unpredictable and disastrous results.

Attention: Do not modify any of the following fields of a buf structure acquired with the geteblk service: the b flags, b forw, b back, b dev, b count, or b un field. Modifying any of these fields can cause unpredictable and disastrous results.

### **Execution Environment**

The **ddstrategy** routine must be coded to execute in an interrupt handler execution environment (device driver bottom half). That is, the routine should neither touch user storage, nor page fault, nor sleep.

### **Return Values**

The ddstrategy routine, unlike other device driver routines, does not return a return code. Any error information is returned in the appropriate fields within the **buf** structure pointed to by the *bp* parameter.

When applicable, the return values defined in the POSIX 1003.1 standard for the read and write subroutines should be used.

### **Related Information**

The **geteblk** kernel service, **iodone** kernel service.

The **buf** structure.

The **read** subroutine, **write** subroutine.

Device Driver Kernel Extension Overview, Understanding Device Driver Structure and Understanding Device Driver Classes, Programming in the Kernel Environment Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## ddwrite Device Driver Entry Point

## **Purpose**

Writes out data to a character device.

## **Syntax**

```
#include <sys/device.h>
#include <sys/types.h>
int ddwrite (devno, uiop, chan, ext)
dev_t devno;
struct uio * uiop;
chan_t chan;
int ext;
```

### **Parameters**

devno Specifies the major and minor device numbers.

Points to a uio structure describing the data area or areas from which to be written. uiop

chan Specifies the channel number. Specifies the extension parameter. ext

# Description

When a program issues a write or writex subroutine call or when the fp rwuio kernel service is used, the kernel calls the **ddwrite** entry point.

This entry point receives a pointer to a **uio** structure, which provides variables used to specify the data transfer operation.

Character device drivers can use the uwritec and uiomove kernel services to transfer data into and out of the user buffer area during a write subroutine call. These services are passed a pointer to the uio structure. They update the fields in the structure by the number of bytes transferred. The only fields in the **uio** structure that are not potentially modified by the data transfer are the uio fmode and uio segflg fields.

For most devices, the **ddwrite** routine queues the request to the device handler and then waits for it to finish. The waiting is typically accomplished by calling the e\_sleep kernel service to wait for an event. The e sleep kernel service suspends the driver and the process that called it and permits other processes to

When the I/O operation is completed, the device usually causes an interrupt, causing the device driver's interrupt handler to be called. The interrupt handler then calls the e\_wakeup kernel service specifying the awaited event, thus allowing the **ddwrite** routine to resume.

The uio resid field initially contains the total number of bytes to write to the device. If the device driver supports it, the uio offset field indicates the byte offset on the device from where the write should start.

The uio offset field is a 64 bit integer (offset t); this allows the file system to send I/O requests to a device driver's read & write entry points which have logical offsets beyond 2 gigabytes. Device drivers must use care not to cause a loss of significance by assigning the offset to a 32 bit variable or using it in calculations that overflow a 32 bit variable.

If no error occurs, the uio resid field should be 0 on return from the ddwrite routine to indicate that all requested bytes were written. If an error occurs, this field should contain the number of bytes remaining to be written when the error occurred.

If a write request starts at a valid device offset but extends past the end of the device's capabilities, no error should be returned. However, the uio resid field should indicate the number of bytes not transferred. If the write starts at or past the end of the device's capabilities, no data should be transferred. An error code of ENXIO should be returned, and the uio resid field should not be modified.

When the **ddwrite** entry point is provided for raw I/O to a block device, this routine usually uses the **uphysio** kernel service to translate requests into block I/O requests.

### **Execution Environment**

The **ddwrite** routine is executed only in the process environment. It should provide the required serialization of its data structures by using the locking kernel services in conjunction with a private lock word defined in the driver.

### **Return Values**

The **ddwrite** entry point can indicate an error condition to the caller by returning a nonzero return value. This causes the subroutine to return a value of -1. It also makes the return code available to the user-mode program in the errno global variable. The error code used should be one of the values defined in the /usr/include/sys/errno.h file.

When applicable, the return values defined in the POSIX 1003.1 standard for the write subroutine should be used.

### **Related Information**

The **ddread** device driver entry point.

## Select/Poll Logic for ddwrite and ddread Routines

## **Description**

The **ddread** and **ddwrite** entry points require logic to support the **select** and **poll** operations. Depending on how the device driver is written, the interrupt routine may also need to include this logic as well.

The select/poll logic is required wherever code checks on the occurrence of desired events. At each point where one of the selection criteria is found to be true, the device driver should check whether a notification is due for that selection. If so, it should call the selnotify kernel service to notify the kernel of the event.

The devno, chan, and revents parameters are passed to the selnotify kernel service to indicate which device and which events have become true.

### **Related Information**

The ddread device driver entry point, ddselect device driver entry point, ddwrite device driver entry point.

The **selnotify** kernel service.

The **poll** subroutine, **select** subroutine.

# **Chapter 3. File System Operations**

# **List of Virtual File System Operations**

The following entry points are specified by the virtual file system interface for performing operations on **vfs** structures:

Entry Point Description

**vfs\_aclxcntl** Issues ACL related control operations for a file system.

vfs\_cntl Issues control operations for a file system.

vfs\_initInitializes a virtual file system.vfs\_mountMounts a virtual file system.

**vfs\_root** Finds the root v-node of a virtual file system.

**vfs\_statfs** Obtains virtual file system statistics.

**vfs\_sync** Forces file system updates to permanent storage.

**vfs\_umount** Unmounts a virtual file system.

**vfs\_vget** Gets the v-node corresponding to a file identifier.

The following entry points are specified by the Virtual File System interface for performing operations on v-node structures:

Entry Point Description

**vnop\_access** Tests a user's permission to access a file.

**vnop\_close** Releases the resources associated with a v-node.

**vnop\_create** Creates and opens a new file.

vnop\_create\_attrvnop\_fclearCreates and opens a new file with initial attributes.Releases portions of a file (by zeroing bytes).

**vnop fid** Builds a file identifier for a v-node.

vnop\_finfovnop\_fsyncReturns pathconf information about a file or file system.Flushes in-memory information and data to permanent storage.

vnop\_fsync\_range Flushes in-memory information and data for a given range to permanent storage.

**vnop\_ftrunc** Decreases the size of a file.

vnop\_getacl Gets information about access control, by retrieving the access control list.

**vnop\_getattr** Gets the attributes of a file.

**vnop\_getxacl** Gets information about access control by retrieving the ACL. Provides an advanced interface

when compared to **vnop\_getacl**.

**vnop\_hold** Assures that a v-node is not destroyed, by incrementing the v-node's use count.

vnop\_ioctl Performs miscellaneous operations on devices.

vnop\_linkCreates a new directory entry for a file.vnop\_lockctlSets, removes, and queries file locks.vnop\_lookupFinds an object by name in a directory.vnop\_mapAssociates a file with a memory segment.

**vnop\_map\_lloff** Associates a file with a memory segment using 64 bit offset.

**vnop\_memcntl** Manages physical attachment of a file.

vnop\_mkdir Creates a directory.

vnop\_mknod Creates a file of arbitrary type.

**vnop\_open** Gets read and/or write access to a file.

vnop\_rdwr Reads or writes a file.

vnop\_rdwr\_attrReads or writes a file and returns attributes.vnop\_readdirReads directory entries in standard format.

**vnop\_readdir\_eofp** Reads directories and returns end of file indication.

**vnop\_readlink** Reads the contents of a symbolic link.

**vnop\_rele** Releases a reference to a virtual node (v-node).

**vnop\_remove** Unlinks a file or directory.

© Copyright IBM Corp. 2010 621

**Entry Point Description** 

Renames a file or directory. vnop\_rename vnop revoke Revokes access to an object.

vnop\_rmdir Removes a directory.

vnop\_seek Moves the current offset in a file. vnop\_select Polls a v-node for pending I/O.

Sets information about access control for a file. vnop\_setacl

vnop setattr Sets attributes of a file.

Sets information about access control for a file. Provides an advanced interface compared to vnop\_setxacl

vnop\_setacl.

vnop\_strategy Reads or writes blocks of a file.

vnop\_symlink Creates a symbolic link.

vnop\_unmap Destroys a file or memory association.

## vfs aclxcntl Entry Point

## **Purpose**

Implements access-control-specific control operations for a file system.

## **Syntax**

```
int vfs_aclxcntl (vfsp, vp, cmd, uiop, argsize, crp)
struct vfs
              *vfsp;
struct vnode *vp;
int
                cmd;
struct uio
             *uiop;
size t
              *argsize;
struct ucred *crp;
```

# **Description**

The vfs\_aclxcntl entry point is invoked to perform various ACL-specific control operations on the underlying physical file system. If a file system is implemented to support this interface, it needs to adhere to the various commands and arguments defined for the interface. A file system implementation can define cmd parameter values and corresponding control functions that are specific to the file system. The cmd parameter for these functions has values defined globally for all the physical file systems. These control operations can be issued with the ACL library interfaces.

#### **Parameters**

Points to the file system for which the control operation is to be issued. vfsp

vp Points to the virtual node pointer to the file path of the file system for which the control operation is

being requested.

cmd

Specifies which control operation to perform. Has one of the following values:

#### ACLCNTL\_GETACLXTYPES

Returns the various ACL types supported for the file system instance. This area is of the following structure type:

```
typedef struct _acl_types_list_t {
    uint32_t num_entries; // in the buffer to follow
    uint32_t pad; // reserved space
    acl_type_t entries[MAX_ACL_TYPES]; // Array of ACL types
} acl_types_list_t;
```

If the buffer space is not enough to accommodate ACL types supported by the physical file system, **errno** is set to **ENOSPC** and the necessary size of the buffer is returned in *argsize*.

#### ACLCNTL\_GETACLXTYPEINFO

Returns the characteristics information related to an ACL type for the file system instance. This area is of the following structure type:

acl\_type\_info is the start byte of the ACL-related characteristics information. ACL characteristics information depends on the ACL type. ACL characteristics for NFS4 ACL type have the following structure:

```
typedef struct __nfs4_acl_type_info_t {
            uint32_t version; // Version of this structure
            uint32_t acl_suport; // Support of Access control entry types.
} nfs4 acl type info t;
```

If the buffer space is not enough to accommodate the ACL types supported by the physical file system, **errno** is set to **ENOSPC** and the necessary size of the buffer is returned in *argsize*.

uiop

Identifies data specific to the control operation. If the *cmd* parameter has a value of

**ACLCNTL\_GETACLXTYPES**, *uiop* points to a buffer area where the file system stores the supported ACL types. If the *cmd* parameter has a value of **ACLCNTL\_GETACLXTYPEINFO**, *uiop* points to a buffer area where the file system stores the ACL characteristics information.

argsize

Identifies the length of the data specified by the *arg* parameter. This buffer is used to return the necessary buffer size, in case the buffer size provided by the user is not enough.

crp

Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

### **Execution Environment**

The vfs\_aclxcntl entry point can be called from the process environment only.

#### Return Values

Upon successful completion, the **vfs\_aclxcntl** entry point returns 0. Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

**EACCES** The *cmd* parameter requires a privilege that the current process does not have.

**EINVAL** Indicates that the *cmd* parameter is not a supported control, or the *arg* parameter is not a

valid argument for the command.

**ENOSPC** The input buffer was not sufficient for storing the requested information.

### **Related Information**

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vfs cntl Entry Point

## **Purpose**

Implements control operations for a file system.

## **Syntax**

```
int vfs_cntl (vfsp, cmd, arg, argsize, crp)
struct vfs * vfsp;
int cmd:
caddr_t arg;
unsigned long argsize;
struct ucred * crp;
```

### **Parameters**

vfsp Points to the file system for which the control operation is to be issued.

Specifies which control operation to perform. cmd arg Identifies data specific to the control operation.

Identifies the length of the data specified by the arg parameter. argsize

Points to the cred structure. This structure contains data that the file system can use to validate access crp

permission.

# **Description**

The vfs\_cntl entry point is invoked by the logical file system to request various control operations on the underlying file system. A file system implementation can define file system-specific cmd parameter values and corresponding control functions. The cmd parameter for these functions should have a minimum value of 32768. These control operations can be issued with the **fscntl** subroutine.

Note: The only system-supported control operation is FS\_EXTENDFS. This operation increases the file system size and accepts an arg parameter that specifies the new size. The FS\_EXTENDFS operation ignores the argsize parameter.

### **Execution Environment**

The **vfs\_cntl** entry point can be called from the process environment only.

### **Return Values**

0 Indicates success.

Non-zero return values are returned from the /usr/include/sys/errno.h file to indicate failure. Typical values include:

**EINVAL** Indicates that the cmd parameter is not a supported control, or the arg parameter is not a valid argument

for the command.

**EACCES** Indicates that the cmd parameter requires a privilege that the current process does not have.

### **Related Information**

The fscntl subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vfs\_hold or vfs\_unhold Kernel Service

## **Purpose**

Holds or releases a vfs structure.

## **Syntax**

```
#include <sys/vfs.h>
void vfs_hold(vfsp)
struct vfs *vfsp;

void vfs_unhold( vfsp)
struct vfs *vfsp;
```

### **Parameter**

*vfsp* Points to a **vfs** structure.

# **Description**

The **vfs\_hold** kernel service holds a **vfs** structure and the **vfs\_unhold** kernel service releases it. These routines manage a use count for a virtual file system (VFS). A use count greater than 1 prevents the virtual file system from being unmounted.

### **Execution Environment**

These kernel services can be called from the process environment only.

### **Return Values**

None

# vfs\_init Entry Point

# **Purpose**

Initializes a virtual file system.

# **Syntax**

```
int vfs_init ( gfsp)
struct gfs *gfsp;
```

### **Parameter**

gfsp Points to a file system's attribute structure.

The **vfs\_init** entry point is invoked to initialize a file system. It is called when a file system implementation is loaded to perform file system-specific initialization.

The **vfs\_init** entry point is not called through the virtual file system switch. Instead, it is called indirectly by the **gfsadd** kernel service when the **vfs\_init** entry point address is stored in the **gfs** structure passed to the **gfsadd** kernel service as a parameter. (The **vfs\_init** address is placed in the gfs\_init field of the **gfs** structure.) The **gfs** structure is defined in the **/usr/include/sys/gfs.h** file.

**Note:** The return value for the **vfs\_init** entry point is passed back as the return value from the **gfsadd** kernel service.

### **Execution Environment**

The vfs\_init entry point can be called from the process environment only.

### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

The gfsadd kernel service.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview in *AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts*.

# vfs\_mount Entry Point

## **Purpose**

Mounts a virtual file system.

# **Syntax**

```
int vfs_mount ( vfsp)
struct vfs *vfsp;
struct ucred * crp;
```

### **Parameter**

*vfsp* Points to the newly created **vfs** structure.

*crp* Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

# **Description**

The **vfs\_mount** entry point is called by the logical file system to mount a new file system. This entry point is called after the **vfs** structure is allocated and initialized. Before this structure is passed to the **vfs\_mount** entry point, the logical file system:

- Guarantees the syntax of the vmount or mount subroutines.
- · Allocates the vfs structure.
- Resolves the stub to a virtual node (v-node). This is the vfs mntdover field in the vfs structure.

· Initializes the following virtual file system fields:

Field Description

vfs flags Initialized depending on the type of mount. This field takes the following values:

VFS\_MOUNTOK

The user has write permission in the stub's parent directory and is the owner of the

stub.

VFS\_SUSER

The user has root user authority.

VFS NOSUID

Execution of setuid and setgid programs from this mount are not allowed.

VFS\_NODEV

Opens of devices from this mount are not allowed.

vfs\_type Initialized to the / (root) file system type when the **mount** subroutine is used. If the **vmount** 

subroutine is used, the vfs\_type field is set to the type parameter supplied by the user. The

logical file system verifies the existence of the type parameter.

vfs ops Initialized according to the vfs type field.

vfs mntdover Identifies the v-node that refers to the stub path argument. This argument is supplied by the

mount or vmount subroutine.

vfs\_date Holds the time stamp. The time stamp specifies the time to initialize the virtual file system.

vfs number Indicates the unique number sequence representing this virtual file system.

vfs mdata Initialized with the **vmount** structure supplied by the user. The virtual file system data is

detailed in the /usr/include/sys/vmount.h file. All arguments indicated by this field are

copied to kernel space.

### **Execution Environment**

The vfs mount entry point can be called from the process environment only.

### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

The mount subroutine, vmount subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview in *AIX*<sup>®</sup> *Version 7.1 Kernel Extensions and Device Support Programming Concepts*.

# vfs\_root Entry Point

# **Purpose**

Returns the root v-node of a virtual file system (VFS).

# **Syntax**

```
int vfs_root ( vfsp, vpp, crp)
struct vfs *vfsp;
struct vnode **vpp;
struct ucred *crp;
```

### **Parameters**

vfsp Points to the vfs structure.

Points to the place to return the v-node pointer. vpp

Points to the cred structure. This structure contains data that the file system can use to validate access crp

permission.

## **Description**

The vfs\_root entry point is invoked by the logical file system to get a pointer to the root v-node of the file system. When successful, the vpp parameter points to the root virtual node (v-node) and the v-node hold count is incremented.

### **Execution Environment**

The vfs\_root entry point can be called from the process environment only.

### Return Values

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Understanding Data Structures and Header Files for Virtual File Systems, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vfs search Kernel Service

# **Purpose**

Searches the vfs list.

# **Syntax**

```
int vfs_search ( vfs srchfcn, srchargs)
(int (*vfs srchfcn)(struct vfs *, caddr_t);
caddr t srchargs;
```

### **Parameters**

Points to a search function. The search function is identified by the vfs\_srchfcn parameter. This vfs srchfcn

> function is used to examine or modify an entry in the vfs list. The search function is called once for each currently active VFS. If the search function returns a value of 0, iteration through the vfs list continues to the next entry. If the return value is nonzero, vfs\_search kernel service

returns to its caller, passing back the return value from the search function.

When the system invokes this function, the system passes it a pointer to a virtual file system

(VFS) and the srchargs parameter.

srchargs Points to data to be used by the search function. This pointer is not used by the vfs search

kernel service but is passed to the search function.

The vfs search kernel service searches the vfs list. This kernel service allows a process outside the file system to search the vfs list. The vfs\_search kernel service locks out all activity in the vfs list during a search. Then, the kernel service iterates through the vfs list and calls the search function on each entry.

The search function must not request locks that could result in deadlock. In particular, any attempt to do lock operations on the vfs list or on other VFS structures could produce deadlock.

The performance of the vfs\_search kernel service may not be acceptable for functions requiring quick response. Iterating through the vfs list and making an indirect function call for each structure is inherently slow.

### **Execution Environment**

The vfs\_search kernel service can be called from the process environment only.

### **Return Values**

This kernel service returns the value returned by the last call to the search function.

## vfs\_statfs Entry Point

## **Purpose**

Returns virtual file system statistics.

# **Syntax**

```
int vfs_stafs ( vfsp, stafsp, crp)
struct vfs *vfsp;
struct statfs *stafsp;
struct ucred *crp;
```

### **Parameters**

vtsp	Points to the <b>vis</b> structure being queried. This structure is defined in the <b>/usr/include/sys/vis.h</b> file.
stafsp	Points to a statfs structure. This structure is defined in the /usr/include/sys/statfs.h file.
crp	Points to the <b>cred</b> structure. This structure contains data that the file system can use to validate access permission.

# **Description**

The vfs\_stafs entry point is called by the logical file system to obtain file system characteristics. Upon return, the vfs\_statfs entry point has filled in the following fields of the statfs structure:

Field	Description
f_blocks	Specifies the number of blocks.
f_files	Specifies the total number of file system objects.
f_bsize	Specifies the file system block size.
f_bfree	Specifies the number of free blocks.
f_ffree	Specifies the number of free file system objects.
f_fname	Specifies a 32-byte string indicating the file system name.
f_fpack	Specifies a 32-byte string indicating a pack ID.
f_name_max	Specifies the maximum length of an object name.

Fields for which a **vfs** structure has no values are set to 0.

### **Execution Environment**

The **vfs\_statfs** entry point can be called from the process environment only.

### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

The **statfs** subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Understanding Data Structures and Header Files for Virtual File Systems, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vfs\_sync Entry Point

### **Purpose**

Requests that file system changes be written to permanent storage.

## **Syntax**

int vfs\_sync (\* gfsp) struct gfs \*gfsp;

### **Parameter**

afsp

Points to a gfs structure. The gfs structure describes the file system type. This structure is defined in the /usr/include/sys/gfs.h file.

# **Description**

The vfs sync entry point is used by the logical file system to force all data associated with a particular virtual file system type to be written to its storage. This entry point is used to establish a known consistent state of the data.

**Note:** The **vfs sync** entry point is called once per file system type rather than once per virtual file system.

### **Execution Environment**

The **vfs\_sync** entry point can be called from the process environment only.

### **Return Values**

The vfs\_sync entry point is advisory. It has no return values.

### **Related Information**

The **sync** subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vfs\_umount Entry Point

## **Purpose**

Unmounts a virtual file system.

## **Syntax**

```
int vfs_umount ( vfsp, crp)
struct vfs *vfsp;
struct ucred *crp;
```

### **Parameters**

vfsp Points to the vfs structure being unmounted. This structure is defined in the /usr/include/sys/vfs.h file. crp Points to the cred structure. This structure contains data that the file system can use to validate access permission.

# **Description**

The vfs umount entry point is called to unmount a virtual file system. The logical file system performs services independent of the virtual file system that initiate the unmounting. The logical file system services:

- · Guarantee the syntax of the uvmount subroutine.
- Perform permission checks:
  - If the *vfsp* parameter refers to a device mount, then the user must have root user authority to perform the operation.
  - If the vfsp parameter does not refer to a device mount, then the user must have root user authority or write permission in the parent directory of the mounted-over virtual node (v-node), as well as write permission to the file represented by the mounted-over v-node.
- · Ensure that the virtual file system being unmounted contains no mount points for other virtual file systems.
- · Ensure that the root v-node is not in use except for the mount. The root v-node is also referred to as the mounted v-node.
- Clear the v mvfsp field in the stub v-node. This prevents lookup operations already in progress from traversing the soon-to-be unmounted mount point.

The logical file system assumes that, if necessary, successful vfs\_umount entry point calls free the root v-node. An error return from the vfs\_umount entry point causes the mount point to be re-established. A 0 (zero) returned from the vfs\_umount entry point indicates the routine was successful and that the vfs structure was released.

#### **Execution Environment**

The **vfs umount** entry point can be called from the process environment only.

### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

The **umount** subroutine, **uvmount** subroutine, **vmount** subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Virtual File System Kernel Extensions Overview, Understanding Data Structures and Header Files for Virtual File Systems, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vfs\_vget Entry Point

### **Purpose**

Converts a file identifier into a virtual node (v-node).

# **Syntax**

```
int vfs vget ( vfsp, vpp, fidp, crp)
struct vfs *vfsp;
struct vnode **vpp;
struct fileid *fidp;
struct ucred *crp;
```

### **Parameters**

Points to the virtual file system that is to contain the v-node. Any returned v-node should belong to this virtual vfsp file system.

vpp Points to the place to return the v-node pointer. This is set to point to the new v-node. The fields in this v-node should be set as follows:

v\_vntype

The type of v-node dependent on private data.

v count

Set to at least 1 (one).

v\_pdata

If a new file, set to the private data for this file system.

fidp Points to a file identifier. This is a file system-specific file identifier that must conform to the **fileid** structure. Note: If the fidp parameter is invalid, the vpp parameter should be set to a null value by the vfs\_vget entry

Points to the cred structure. This structure contains data that the file system can use to validate access crp permission.

# **Description**

The vfs\_vget entry point is called to convert a file identifier into a v-node. This entry point uses information in the vfsp and fidp parameters to create a v-node or attach to an existing v-node. This v-node represents, logically, the same file system object as the file identified by the fidp parameter.

If the v-node already exists, successful operation of this entry point increments the v-node use count and returns a pointer to the v-node. If the v-node does not exist, the vfs vget entry point creates it using the vn\_get kernel service and returns a pointer to the new v-node.

#### **Execution Environment**

The **vfs\_vget** entry point can be called from the process environment only.

#### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure. A typical value includes:

EINVAL

Indicates that the remote virtual file system specified by the *vfsp* parameter does not support chained mounts.

#### **Related Information**

The vn\_get kernel service.

The access subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vnop\_access Entry Point

## **Purpose**

Requests validation of user access to a virtual node (v-node).

# **Syntax**

```
int vnop_access ( vp, mode, who, crp)
struct vnode *vp;
int mode;
int who;
struct ucred *crp;
```

#### **Parameters**

*vp* Points to the v-node.

mode Identifies the access mode.

who Specifies the IDs for which

Specifies the IDs for which to check access. This parameter should be one of the following values, which are defined in the /usr/include/sys/access.h file:

#### ACC\_SELF

Determines if access is permitted for the current process. The effective user and group IDs and the supplementary group ID of the current process are used for the calculation.

#### ACC ANY

Determines if the specified access is permitted for any user, including the object owner. The *mode* parameter must contain only one of the valid modes.

#### **ACC\_OTHERS**

Determines if the specified access is permitted for any user, excluding the owner. The *mode* parameter must contain only one of the valid modes.

#### ACC ALL

crp

Determines if the specified access is permitted for all users. (This is a useful check to make when files are to be written blindly across networks.) The *mode* parameter must contain only one of the valid modes.

Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

## **Description**

The **vnop\_access** entry point is used by the logical volume file system to validate access to a v-node. This entry point is used to implement the access subroutine. The v-node is held for the duration of the **vnop access** entry point. The v-node count is unchanged by this entry point.

In addition, the vnop\_access entry point is used for permissions checks from within the file system implementation. The valid types of access are listed in the /usr/include/sys/access.h file. Current modes are read, write, execute, and existence check.

Note: The vnop\_access entry point must ensure that write access is not requested on a read-only file system.

### **Execution Environment**

The **vnop\_access** entry point can be called from the process environment only.

#### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure. A typical value includes:

**EACCES** Indicates no access is allowed.

### **Related Information**

The access subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_close Entry Point

# **Purpose**

Closes a file associated with a v-node (virtual node).

# **Syntax**

```
int vnop_close ( vp, flag, vinfo, crp)
struct vnode *vp;
int flag;
caddr t vinfo;
struct ucred *crp;
```

#### **Parameters**

Points to the v-node.

flag Identifies the flag word from the file pointer.

vinfo This parameter is not used.

crp Points to the cred structure. This structure contains data that the file system can use to validate access

permission.

# **Description**

The **vnop\_close** entry point is used by the logical file system to announce that the file associated with a given v-node is now closed. The v-node continues to remain active but will no longer receive read or write requests through the **vnop\_rdwr** entry point.

A **vnop\_close** entry point is called only when the use count of an associated file structure entry goes to 0 (zero).

Note: The v-node is held over the duration of the vnop\_close entry point.

#### **Execution Environment**

The **vnop\_close** entry point can be called from the process environment only.

### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

**Note:** The **vnop\_close** entry point may fail and an error will be returned to the application. However, the v-node is considered closed.

### **Related Information**

The **close** subroutine.

The vnop\_open entry point, vnop\_rele entry point.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_create Entry Point

# **Purpose**

Creates a new file.

# **Syntax**

```
int vnop_create (dp, vpp, flag, pname, mode, vinfop, crp)
struct vnode * dp;
struct vnode ** vpp;
int flag;
char * pname;
int mode;
caddr_t * vinfop;
struct ucred * crp;
```

#### **Parameters**

dp Points to the virtual node (v-node) of the parent directory.

*vpp* Points to the place in which the pointer to a v-node for the newly created file is returned.

flag Specifies an integer flag word. The **vnop\_create** entry point uses this parameter to open the file.

Points to the name of the new file. pname Specifies the mode for the new file. mode

vinfop This parameter is unused.

crp Points to the cred structure. This structure contains data that the file system can use to validate access

permission.

## **Description**

The vnop\_create entry point is invoked by the logical file system to create a regular (v-node type VREG) file in the directory specified by the dp parameter. (Other v-node operations create directories and special files.) Virtual node types are defined in the /usr/include/sys/vnode.h file. The v-node of the parent directory is held during the processing of the vnop\_create entry point.

To create a file, the **vnop\_create** entry point does the following:

- · Opens the newly created file.
- Checks that the file system associated with the directory is not read-only.

**Note:** The logical file system calls the **vnop lookup** entry point before calling the **vnop create** entry point.

### **Execution Environment**

The **vnop\_create** entry point can be called from the process environment only.

### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

The vnop\_lookup entry point.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_create\_attr Entry Point

# **Purpose**

Creates a new file.

# **Syntax**

vnop create attr (dvp, vpp, flags, name, vap, vcf, finfop, crp) struct vnode \*dvp; struct vnode \*vpp; int flags; char \*name; struct vattr \*vap;

int vcf;
caddr\_t finfop;
struct ucred \*crp;

#### **Parameters**

*dvp* Points to the directory vnode.

*vpp* Points to the newly created vnode pointer.

flags Specifies file creation flags.

name Specifies the name of the file to create.

vattr Points to the initial attributes.

vcf Specifies create flags.

finfop Specifies address of finfo field. crp Specifies user's credentials.

### **Description**

The **vnop\_create\_attr** entry point is used to create a new file. This operation is similar to the vnop\_create entry point except that the initial file attributes are passed in a vattr structure.

The va\_mask field in the vattr structure identifies which attributes are to be applied. For example, if the AT\_SIZE bit is set, then the file system should use va\_size for the initial file size. For all vnop\_create\_attr calls, at least AT\_TYPE and AT\_MODE must be set.

The vcf parameter controls how the new vnode is to be activated. If vcf is set to VC\_OPEN, then the new object should be opened. If vcf is VC\_LOOKUP, then the new object should be created, but not opened. If vcf is VC\_DEFAULT, then the new object should be created, but the vnode for the object is not activated.

File systems that do not define GFS\_VERSION421 in their gfs flags do not need to supply a vnop\_create\_attr entry point. The logical file system will funnel all creation requests through the old vnop\_create entry point.

#### **Execution Environment**

The vnop\_create\_attr entry point can be called from the process environment only.

#### **Return Values**

**Zero** Indicates a successful operation; \*vpp contains a pointer to the new vnode.

Nonzero Indicates that the operation failed; return values should be chosen from the /usr/include/sys/errno.h

file.

#### **Related Information**

The open subroutine, mknod subroutine.

Virtual File System Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes), and Virtual File System Kernel Extensions Overview.

List of Virtual File System Operations.

# vnop\_fclear Entry Point

# **Purpose**

Releases portions of a file.

## **Syntax**

```
int vnop_fclear (vp, flags, offset, len, vinfo, crp)
struct vnode * vp;
int flags;
offset t offset;
offset_t len;
caddr t vinfo;
struct ucred * crp;
```

#### **Parameters**

Points to the virtual node (v-node) of the file. vp Identifies the flags from the open file structure. flags offset Indicates where to start clearing in the file. len Specifies the length of the area to be cleared.

This parameter is unused. vinfo

Points to the cred structure. This structure contains data that the file system can use to validate access crp

permission.

# **Description**

The vnop\_fclear entry point is called from the logical file system to clear bytes in a file, returning whole free blocks to the underlying file system. This entry point performs the clear regardless of whether the file is mapped.

Upon completion of the vnop\_fclear entry point, the logical file system updates the file offset to reflect the number of bytes cleared.

#### **Execution Environment**

The **vnop** fclear entry point can be called from the process environment only.

#### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

The fclear subroutine.

# vnop fid Entry Point

# **Purpose**

Builds a file identifier for a virtual node (v-node).

## **Syntax**

```
int vnop_fid ( vp, fidp, crp)
struct vnode *vp;
struct fileid *fidp;
struct ucred *crp;
```

### **Parameters**

vp Points to the v-node that requires the file identifier.

fidp Points to where to return the file identifier.

Points to the cred structure. This structure contains data that the file system can use to validate access crp permission.

# **Description**

The vnop\_fid entry point is invoked to build a file identifier for the given v-node. This file identifier must contain sufficient information to find a v-node that represents the same file when it is presented to the vfs get entry point.

### **Execution Environment**

The **vnop\_fid** entry point can be called from the process environment only.

### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_finfo Entry Point

# **Purpose**

Returns information about a file.

# **Syntax**

vnop\_finfo (vp, cmd, bufp, length, crp) struct vnode \*vp; int cmd; void \*bufp; int length; struct ucred \*crp:

#### **Parameters**

Points to the vnode to be queried. vp

cmd Specifies the command parameter. bufp Points to the buffer for the information. length Specifies the length of the buffer. crp Specifies user's credentials.

## **Description**

The vnop\_finfo entry point is used to query a file system. It is used primarily to implement the pathconf and **fpathconf** subroutines. The **command** parameter defines what type of guery is being done. The query commands and the associated data structures are defined in <sys/finfo.h>. If the file system does not support the particular query, it should return ENOSYS.

File systems that do not define GFS\_VERSION421 in their gfs flags do not need to supply a vnop\_finfo entry point. If the command is FI\_PATHCONF, then the logical file system returns generic pathconf information. If the query is other than FI\_PATHCONF, then the request fails with EINVAL.

### **Execution Environment**

The **vnop\_finfo** entry point can be called from the process environment only.

### **Return Values**

Zero Indicates a successful operation.

Nonzero Indicates that the operation failed; return values should be chosen from the /usr/include/sys/errno.h

file.

#### **Related Information**

The pathconf, fpathconf subroutine.

Virtual File System Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts, and Virtual File System Kernel Extensions Overview.

# vnop\_fsync, vnop\_fsync\_range Entry Points

# **Purpose**

Flushes file data from memory to disk.

# **Syntax**

```
int vnop fsync ( vp, flags, vinfo, crp)
struct vnode *vp;
long flags;
long vinfo;
struct ucred *crp;
int vnop fsync range (vp, flags, vinfo, offset, length, crp)
struct vnode *vp;
long flags;
long vinfo;
offset t offset;
offset t length;
struct ucred *crp;
```

#### **Parameters**

Points to the virtual node (v-node) of the file.

flags Identifies flags from the open file plus flags that govern the action to be taken. It can be one of the

following values:

**FDATASYNC** 

Writes file data and metadata to retrieve the data for the specified range.

**FFILESYNC** 

Writes all modified file data and metadata for the specified range.

**FNOCACHE** 

Writes the data in the range and releases full memory pages in the byte range. The data

will no longer be in the cache.

vinfo This parameter is currently not used.

offset Specifies the starting offset in the file of the data to be flushed.

length Specifies the length of the data to be flushed.

crp Points to the **cred** structure. This structure contains data that the file system can use to validate

access permission.

## **Description**

The **vnop\_fsync** entry point is called by the logical file system to request that all modifications associated with a given v-node to be flushed out to permanent storage. This must be done synchronously so that the caller can assure that all I/O has completed successfully. The **vnop\_fsync\_range** entry point provides the same function but limits the data to be written to a specified range in the file.

### **Execution Environment**

The vnop\_fsync and vnop\_fsync\_range entry points can be called from the process environment only.

#### **Return Values**

0 Indicates success.

Nonzero values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

The **fsync** subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_ftrunc Entry Point

# **Purpose**

Truncates a file.

# **Syntax**

```
int vnop_ftrunc (vp, flags, length, vinfo, crp)
struct vnode * vp;
int flags;
```

```
offset_t length;
caddr t vinfo;
struct ucred * crp;
```

#### **Parameters**

vp Points to the virtual node (v-node) of the file. flags Identifies flags from the open file structure.

length Specifies the length to which the file should be truncated.

vinfo This parameter is unused.

Points to the cred structure. This structure contains data that the file system can use to validate access crp

permission.

## **Description**

The vnop\_ftrunc entry point is invoked by the logical file system to decrease the length of a file by truncating it. This operation is unsuccessful if any process other than the caller has locked a portion of the file past the specified offset.

### **Execution Environment**

The **vnop\_ftrunc** entry point can be called from the process environment only.

### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

The ftruncate subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_getacl Entry Point

# **Purpose**

Retrieves the access control list (ACL) for a file.

# **Syntax**

```
#include <svs/acl.h>
int vnop_getacl ( vp, uiop, crp)
struct vnode *vp;
struct uio *uiop;
struct ucred *crp;
```

# **Description**

The vnop\_getacl entry point is used by the logical file system to retrieve the access control list (ACL) for a file to implement the getacl subroutine.

### **Parameters**

vp	Specifies the virtual node (v-node) of the file system object.
uiop	Specifies the <b>uio</b> structure that defines the storage for the ACL.

Points to the cred structure. This structure contains data that the file system can use to validate access crp permission.

### **Execution Environment**

The vnop\_getacl entry point can be called from the process environment only.

#### **Return Values**

Indicates a successful operation.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure. A valid value includes:

**ENOSPC** 

Indicates that the buffer size specified in the *uiop* parameter was not large enough to hold the ACL. If this is the case, the first word of the user buffer (data in the uio structure specified by the uiop parameter) is set to the appropriate size.

### **Related Information**

The chacl subroutine, chmod subroutine, chown subroutine, statacl subroutine.

# vnop\_getattr Entry Point

# **Purpose**

Gets the attributes of a file.

# **Syntax**

```
int vnop getattr ( vp, vap, crp)
struct vnode *vp;
struct vattr *vap;
struct ucred *crp;
```

#### **Parameters**

- Specifies the virtual node (v-node) of the file system object. vp
- Points to a vattr structure.
- Points to the cred structure. This structure contains data that the file system can use to validate access crp permission.

# **Description**

The **vnop\_getattr** entry point is called by the logical file system to retrieve information about a file. The **vattr** structure indicated by the *vap* parameter contains all the relevant attributes of the file. The **vattr** structure is defined in the **/usr/include/sys/vattr.h** file. This entry point is used to implement the **stat**, **fstat**, and **lstat** subroutines.

**Note:** The indicated v-node is held for the duration of the **vnop\_getattr** subroutine.

### **Execution Environment**

The vnop\_getattr entry point can be called from the process environment only.

### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

The statx subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vnop\_getxacl Entry Point

# **Purpose**

Retrieves the access control list (ACL) for a file. This is an advanced version of vnop\_getacl interface.

# **Syntax**

# Description

The **vnop\_getxacl** entry point retrieves the access control list (ACL) for a file system object. It is an advanced version of **vnop\_getacl** interface and provides for ACL-type-based operations. Note that this interface can be used to obtain the ACL type and length information, without actually retrieving the ACL data (see the *ctl\_flags* description for more details).

#### **Parameters**

vp

Specifies the virtual node (v-node) of the file system object.

acl\_type Points to buffer space for file systems to return the ACL type associated with the file

> system object. The value should normally be set to ACL\_ANY or 0 when the call is made. Some physical file systems can solicit ACL requests for a particular ACL type. In such cases, the caller provides the ACL type requested in this buffer. Note: The latter issue is file system implementation specific. For example, when ACL information is requested with an input ACL type, a physical file system might return an error if the existing ACL associated with the file system object is of a different ACL type. Or, the file system might emulate an ACL of the type requested

and return.

acl\_len Pointer to a length variable. The space pointed to is used as an input, as well as

output, parameter. As input, the value will indicate the size of buffer uiop. When the call returns, this space holds the actual length of the ACL (true for when the call is

successful or when the call fails with errno set to ENOSPC).

ctl flags A 64-bit bit mask that provides control over the ACL retrieval and for any future

variations in the interface. The following value is defined for these flags:

GET\_ACLINFO\_ONLY

Gets only the ACL type and length information from the underlying file system. When this bit is set, arguments such as mode\_info can be set to NULL. All other cases must be valid buffer pointers or else an error is returned. If this bit is not specified, all the other information about the ACL

(such as ACL data and mode information) is returned.

aoiu Specifies the **uio** structure that provides space for the store of the ACL.

mode\_info This value indicates any mode word information that needs to be retrieved for the

file system object as part of this ACL get operation.

Points to the **cred** structure. This structure contains data that the file system can crp

use to validate access permission.

#### **Execution Environment**

The **vnop\_getxacl** entry point can be called from the process environment only.

### **Return Values**

Upon successful completion, the vnop\_getxacl entry point returns 0. Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

**ENOSPC** Indicates that the buffer size specified in the *uiop* parameter was not large enough to hold

the ACL.

Note: This list of error numbers is not complete and is dependent on the particular physical file system implementation supporting the ACL.

#### **Related Information**

The chacl subroutine, chown subroutine, chmod subroutine, statacl subroutine, "vnop getacl Entry Point" on page 642, "vnop setxacl Entry Point" on page 670.

The **uio** structure.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_hold Entry Point

## **Purpose**

Assures that a virtual node (v-node) is not destroyed.

## **Syntax**

```
int vnop_hold ( vp)
struct vnode *vp;
```

#### **Parameter**

vp Points to the v-node.

## **Description**

The **vnop\_hold** entry point increments the v\_count field, the hold count on the v-node, and the v-node's underlying g-node (generic node). This incrementation assures that the v-node is not deallocated.

### **Execution Environment**

The **vnop\_hold** entry point can be called from the process environment only.

### **Return Values**

The **vnop** hold entry point cannot fail and therefore has no return values.

#### **Related Information**

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes), Understanding Generic I-nodes (G-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_ioctl Entry Point

# **Purpose**

Requests I/O control operations on special files.

# **Syntax**

```
int vnop_ioctl (vp, cmd, arg, flags, ext, crp)
struct vnode * vp;
int cmd;
caddr_t arg;
int flags, ext;
struct ucred * crp;
```

### **Parameters**

*vp* Points to the virtual node (v-node) on which to perform the operation.

cmd Identifies the specific command. Common operations for the **ioctl** subroutine are defined in the

/usr/include/sys/ioctl.h file. The file system implementation can define other ioctl operations.

Defines a command-specific argument. This parameter can be a single word or a pointer to an argument

(or result structure).

flags Identifies flags from the open file structure.

arg

Specifies the extended parameter passed by the ioctl subroutine. The ioctl subroutine always sets the ext ext parameter to 0.

Points to the cred structure. This structure contains data that the file system can use to validate access crp permission.

## **Description**

The **vnop ioctl** entry point is used by the logical file system to perform miscellaneous operations on special files. If the file system supports special files, the information is passed down to the ddioctl entry point of the device driver associated with the given v-node.

#### **Execution Environment**

The **vnop** ioctl entry point can be called from the process environment only.

### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure. A valid value includes:

**EINVAL** Indicates the file system does not support the entry point.

### **Related Information**

The ioctl subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop link Entry Point

# **Purpose**

Requests a hard link to a file.

# **Syntax**

```
int vnop_link ( vp, dp, name, crp)
struct vnode *vp;
struct vnode *dp;
caddr t *name;
struct ucred *crp;
```

### **Parameters**

Vρ Points to the virtual node (v-node) to link to. This v-node is held for the duration of the linking process.

Points to the v-node for the directory in which the link is created. This v-node is held for the duration of the dp linking process.

Identifies the new name of the entry. name

Points to the cred structure. This structure contains data that the file system can use to validate access crp permission.

## **Description**

The vnop\_link entry point is invoked to create a new hard link to an existing file as part of the link subroutine. The logical file system ensures that the dp and vp parameters reside in the same virtual file system, which is not read-only.

### **Execution Environment**

The **vnop\_link** entry point can be called from the process environment only.

#### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vnop\_lockctl Entry Point

## **Purpose**

Sets, checks, and queries record locks.

# **Syntax**

```
int vnop_lockctl (vp, offset, lckdat, cmd, retry fn, retry id, crp)
struct vnode * vp;
offset t offset;
struct eflock * lckdat;
int cmd:
int (* retry fn)();
caddr_t retry id;
struct ucred * crp;
```

#### **Parameters**

Points to the file's virtual node (v-node). vp

offset Indicates the file offset from the open file structure. This parameter is used to establish where the

lock region begins.

lckdat Points to the **elock** structure. This structure describes the lock operation to perform.

Identifies the type of lock operation the **vnop locketl** entry point is to perform. It is a bit mask that

takes the following lock-control values:

SETFLCK

If set, performs a lock set or clear. If clear, returns the lock information. The 1 type field in the **eflock** structure indicates whether a lock is set or cleared.

**SLPFLCK** 

If the lock is unavailable immediately, wait for it. This is only valid when the SETFLCK flag is

cmd

Points to a subroutine that is called when a lock is retried. This subroutine is not used if the lock is retry\_fn granted immediately. Note: If the retry\_fn parameter is not a null value, the vnop\_lockctl entry point will not sleep, regardless of the SLPFLCK flag. Points to the location where a value can be stored. This value can be used to correlate a retry retry\_id operation with a specific lock or set of locks. The retry value is only used in conjunction with the retry\_fn parameter. Note: This value is an opaque value and should not be used by the caller for any purpose other than a lock correlation. (This value should not be used as a pointer.) Points to the cred structure. This structure contains data that the file system can use to validate crp

## **Description**

access permission.

The vnop\_lockctl entry point is used to request record locking. This entry point uses the information in the eflock structure to implement record locking.

If a requested lock is blocked by an existing lock, the **vnop locketl** entry point should establish a sleeping lock with the retry subroutine address (specified by the retry\_fn parameter) stored in the entry point. The vnop lockctl entry point then returns a correlating ID value to the caller (in the retry id parameter), along with an exit value of EAGAIN. When the sleeping lock is later awakened, the retry subroutine is called with the *retry\_id* parameter as its argument.

#### eflock Structure

The eflock structure is defined in the /usr/include/sys/flock.h file and includes the following fields:

Field	Description
1_type	Specifies type of lock. This field takes the following values:
	F_RDLCK Indicates read lock.
	F_WRLCK Indicates write lock.
	<b>F_UNLCK</b> Indicates unlock this record. A value of <b>F_UNLCK</b> starting at 0 until 0 for a length of 0 means unlock all locks on this file. Unlocking is done automatically when a file is closed.
1 whence	Specifies location that the 1 start field offsets.
_ l_start	Specifies offset from the 1 whence field.
1_1en	Specifies length of record. If this field is 0, the remainder of the file is specified.
1_vfs	Specifies virtual file system that contains the file.
l_sysid	Specifies value that uniquely identifies the host for a given virtual file system. This field must be filled in before the call to the <b>vnop_lockctl</b> entry point.
l_pid	Specifies process ID (PID) of the lock owner. This field must be filled in before the call to the <b>vnop_lockctl</b> entry point.

### **Execution Environment**

The **vnop lockctl** entry point can be called from the process environment only.

#### Return Values

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure. Valid values include:

**EAGAIN** Indicates a blocking lock exists and the caller did not use the SLPFLCK flag to request that the operation

**ERRNO** Returns an error number from the /usr/include/sys/errno.h file on failure.

### **Related Information**

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop lookup Entry Point

## **Purpose**

Returns a v-node for a given name in a directory.

# **Syntax**

```
int vnop lookup (dvp, vpp, name, vattrp , crp)
struct vnode * dvp:
struct vnode ** vpp;
char * name;
struct vattr * vattrp;
struct ucred * crp;
```

### **Parameters**

dvp Points to the virtual node (v-node) of the directory to be searched. The logical file system verifies that this

v-node is of a VDIR type.

Points to a null-terminated character string containing the file name to look up. name

Points to a vattr structure. If this pointer is NULL, no action is required of the file system implementation. vattrp

If it is not NULL, the attributes of the file specified by the name parameter are returned at the address

passed in the vattrp parameter.

Points to the place to which to return the v-node pointer, if the pointer is found. Otherwise, a null vpp

character should be placed in this memory location.

Points to the cred structure. This structure contains data that the file system can use to validate access crp

permission.

# **Description**

The vnop\_lookup entry point is invoked by the logical file system to find a v-node. It is used by the kernel to convert application-given path names to the v-nodes that represent them.

The use count in the v-node specified by the dvp parameter is incremented for this operation, and it is not decremented by the file system implementation.

If the name is found, a pointer to the desired v-node is placed in the memory location specified by the vpp parameter, and the v-node hold count is incremented. (In this case, this entry point returns 0.) If the file name is not found, a null character is placed in the vpp parameter, and the function returns a ENOENT value. Errors are reported with a return code from the /usr/include/sys/errno.h file. Possible errors are usually specific to the particular virtual file system involved.

#### **Execution Environment**

The **vnop\_lookup** entry point can be called from the process environment only.

### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vnop\_map Entry Point

## **Purpose**

Validates file mapping requests.

# **Syntax**

```
int vnop_map (vp, addr, length, offset, flags, crp)
struct vnode * vp;
caddr_t addr;
uint length;
uint offset;
uint flags;
struct ucred * crp;
```

#### **Parameters**

**Note:** The *addr*, *offset*, and *length* parameters are unused in the current implementation. The file system is expected to store the segment ID with the file in the gn seg field of the g-node for the file.

*vp* Points to the virtual node (v-node) of the file.

addr Identifies the location within the process address space where the mapping is to begin.

length Specifies the maximum size to be mapped.

offset Specifies the location within the file where the mapping is to begin.

flags Identifies what type of mapping to perform. This value is composed of bit values defined in the

/usr/include/sys/shm.h file. The following values are of particular interest to file system implementations:

#### SHM\_RDONLY

The virtual memory object is read-only.

#### SHM\_COPY

The virtual memory object is copy-on-write. If this value is set, updates to the segment are deferred until an **fsync** operation is performed on the file. If the file is closed without an **fsync** operation, the modifications are discarded. The application that called the **vnop\_map** entry point is also responsible for calling the **vnop\_fsync** entry point.

**Note:** Mapped segments do not reflect modifications made to a copy-on-write segment.

Points to the **cred** structure. This structure contains data that applications can use to validate access permission.

# **Description**

crp

The **vnop\_map** entry point is called by the logical file system to validate mapping requests resulting from the **mmap** or **shmat** subroutines. The logical file system creates the virtual memory object (if it does not already exist) and increments the object's use count.

The **vnop\_map** entry point can be called from the process environment only.

### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

The **shmat** subroutine, **vnop fsync** entry point.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vnop\_map\_lloff Entry Point

## **Purpose**

Announces intention to map a file.

# **Syntax**

int vnop\_map\_lloff (vp, addr, length, offset, mflags, fflags, crp) struct vnode \*vp; caddr\_t addr, offset\_t length; offset\_t offset; int mflags: int fflags;

struct ucred \*crp:

### **Parameters**

vp Points to the vnode to be queried.

addr Unused.

length Specifies the length of the mapping request. offset Specifies the starting offset for the map request.

mflags Specifies the mapping flags. fflags Specifies the file flags. Specifies user's credentials. crp

# **Description**

The vnop\_map\_lloff entry point is used to tell the file system that the file is going to be accessed by memory mapped loads and stores. The file system should fail the request if it does not support memory mapping. This interface allows applications to specify starting offsets that are larger than 2 gigabytes.

File systems that do not define GFS\_VERSION421 in their gfs flags do not need to supply a vnop\_map\_lloff entry point.

The vnop\_map\_lloff entry point can be called from the process environment only.

#### **Return Values**

**Zero** Indicates a successful operation.

Nonzero Indicates that the operation failed; return values should be chosen from the /usr/include/sys/errno.h

file.

### **Related Information**

The **shmat** and **mmap** subroutines.

Virtual File System Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts, and Virtual File System Kernel Extensions Overview.

## vnop\_memcntl Entry Point

## **Purpose**

Changes or queries the physical attachment of a file.

# **Syntax**

```
#include <sys/vnode.h>
#include <sys/fcntl.h>

int vnop_memcntl (vnode, cmd, arg, crp)
struct gnode * vnode;
int cmd;
void * arg;
struct ucred * crp;
```

#### **Parameters**

vnode Points to the virtual node of the file

cmd Specifies the operation to be performed. The cmd parameter can be one of the following values:

F\_ATTACHF\_DETACHF\_ATTINFO

arg Points to a structure containing the attach\_desc\_t, detach\_desc\_t or attinfo\_desc\_t information

according to the specified *cmd* parameter. **F\_ATTACH** attach\_desc\_t **F\_DETACH** detach\_desc\_t **F\_ATTINFO** attinfo\_desc\_t

crp Points to the cred structure. This structure contains data that the file system can use to validate

access permission.

# Description

The **vnop\_memcntl** entry point requests memory attachment operations as specified by the *cmd* parameter. The *cmd* parameter determines the *arg* structure.

The **vnop\_memcntl** entry point can be called from the process environment only.

### **Return Values**

Success. non-zero Failure.

### **Related Information**

Workload management in AIX Version 7.1 Operating system and device management.

# vnop\_mkdir Entry Point

## **Purpose**

Creates a directory.

# **Syntax**

```
int vnop mkdir ( dp, name, mode, crp)
struct vnode *dp;
caddr t name;
int mode;
struct ucred *crp;
```

### **Parameters**

dp Points to the virtual node (v-node) of the parent directory of a new directory. This v-node is held for the duration of the entry point.

Specifies the name of a new directory. name

Specifies the permission modes of a new directory. mode

Points to the cred structure. This structure contains data that the file system can use to validate access crp

permission.

# **Description**

The **vnop mkdir** entry point is invoked by the logical file system as the result of the **mkdir** subroutine. The vnop\_mkdir entry point is expected to create the named directory in the parent directory associated with the dp parameter. The logical file system ensures that the dp parameter does not reside on a read-only file system.

#### **Execution Environment**

The **vnop\_mkdir** entry point can be called from the process environment only.

#### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

The **mkdir** subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vnop\_mknod Entry Point

## **Purpose**

Creates a special file.

## **Syntax**

```
int vnop_mknod (dvp, name, mode, dev, crp)
struct vnode * dvp;
caddr t * name;
int mode;
dev_t dev;
struct ucred * crp;
```

#### **Parameters**

Points to the virtual node (v-node) for the directory to contain the new file. This v-node is held for the dvp duration of the **vnop\_mknod** entry point.

name Specifies the name of a new file.

mode Identifies the integer mode that indicates the type of file and its permissions.

dev Identifies an integer device number.

Points to the cred structure. This structure contains data that applications can use to validate access crp

permission.

# **Description**

The **vnop\_mknod** entry point is invoked by the logical file system as the result of a **mknod** subroutine. The underlying file system is expected to create a new file in the given directory. The file type bits of the mode parameter indicate the type of file (regular, character special, or block special) to be created. If a special file is to be created, the dev parameter indicates the device number of the new special file.

The logical file system verifies that the *dvp* parameter does not reside in a read-only file system.

#### **Execution Environment**

The **vnop mknod** entry point can be called from the process environment only.

#### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

The **mknod** subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vnop\_open Entry Point

## **Purpose**

Requests that a file be opened for reading or writing.

## **Syntax**

```
int vnop open (vp, flag, ext, vinfop, crp)
struct vnode * vp;
int flag;
caddr_t ext;
caddr_t vinfop;
struct ucred * crp;
```

#### **Parameters**

Points to the virtual node (v-node) associated with the desired file. The v-node is held for the duration of

the open process.

Specifies the type of access. Access modes are defined in the /usr/include/sys/fcntl.h file. flag

**Note:** The **vnop\_open** entry point does not use the FCREAT mode.

Points to external data. This parameter is used if the subroutine is opening a device. ext

vinfop This parameter is not currently used.

crp Points to the cred structure. This structure contains data that the file system can use to validate access

permission.

# **Description**

The vnop open entry point is called to initiate a process access to a v-node and its underlying file system object. The operation of the vnop open entry point varies between virtual file system (VFS) implementations. A successful vnop open entry point must leave a v-node count of at least 1.

The logical file system ensures that the process is not requesting write access (with the FWRITE or FTRUNC mode) to a read-only file system.

#### **Execution Environment**

The **vnop open** entry point can be called from the process environment only.

#### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

The **open** subroutine.

The **vnop\_close** entry point.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_rdwr, vnop\_rdwr\_attr Entry Points

## **Purpose**

Requests file I/O.

# **Syntax**

```
int vnop_rdwr (vp, op, flags, uiop, ext, vinfo, vattrp, crp)
struct vnode * vp;
enum uio_rw op;
int flags;
struct uio * uiop;
int ext;
caddr_t vinfo;
struct vattr * vattrp;
struct ucred * crp;
int vnop_rdwr_attr (vp, op, flags, uiop, ext, vinfo, vpre, vpost, crp)
struct vnode * vp;
enum uio_rw op;
long flags;
struct uio * uiop;
ext t ext;
caddr t vinfo;
struct vattr * vpre;
struct vattr * vpost;
struct ucred * crp;
```

### **Parameters**

vp	Points to the virtual node (v-node) of the file.
op	Specifies a number that indicates a read or write operation. This parameter has a value of either UIO_READ or UIO_WRITE. These values are found in the /usr/include/sys/uio.h file.
flags	Identifies flags from the open file structure.
uiop	Points to a <b>uio</b> structure. This structure describes the count, data buffer, and other I/O information.
ext	Provides an extension for special purposes. Its use and meaning are specific to virtual file systems, and
	it is usually ignored except for devices.
vinfo	This parameter is currently not used.
vattrp	Points to a <b>vattr</b> structure. If this pointer is NULL, no action is required of the file system implementation. If it is not NULL, the attributes of the file specified by the <i>vp</i> parameter are returned at the address passed in the <i>vattrp</i> parameter.
vpre	Points to an attributes structure for pre-operation attributes.
vpost	Points to an attributes structure for post-operation attributes.
crp	Points to the <b>cred</b> structure. This structure contains data that the file system can use to validate access permission.

# **Description**

The vnop\_rdwr entry point is used to request that data to be read or written from an object represented by a v-node. The vnop\_rdwr entry point does the indicated data transfer and sets the number of bytes not transferred in the uio\_resid field. This field is 0 (zero) on successful completion.

The vnop\_rdwr\_attr kernel service performs the same function as the vnop\_rdwr kernel service but also allows the caller to retrieve attributes of the object either before the I/O, after or both.

The vnop\_rdwr and vnop\_rdwr\_attr entry points can be called from the process environment only.

### **Return Values**

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure. The vnop\_rdwr entry point returns an error code if an operation did not transfer all the data requested. The only exception is if an end of file is reached on a read request. In this case, the operation still returns 0.

#### **Related Information**

The **vnop\_create** entry point, **vnop\_open** entry point.

The **read** subroutine, **write** subroutine.

Virtual File System Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes), and Virtual File System Kernel Extensions Overview in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_readdir Entry Point

## **Purpose**

Reads directory entries in standard format.

# **Syntax**

```
int vnop readdir ( vp, uiop, crp)
struct vnode *vp;
struct uio *uiop;
struct ucred *crp;
```

#### **Parameters**

vp Points to the virtual node (v-node) of the directory.

Points to the uio structure that describes the data area into which to put the block of dirent structures. The uiop starting directory offset is found in the uiop->uio offset field and the size of the buffer area is found in the uiop->uio resid field.

Points to the cred structure. This structure contains data that the file system can use to validate access crp permission.

# **Description**

The vnop\_readdir entry point is used to access directory entries in a standard way. These directories should be returned as an array of dirent structures. The /usr/include/sys/dir.h file contains the definition of a dirent structure.

The **vnop\_readdir** entry point does the following:

- Copies a block of directory entries into the buffer specified by the uiop parameter.
- Sets the uiop->uio resid field to indicate the number of bytes read.

The End-of-file character should be indicated by not reading any bytes (not by a partial read). This provides directories with the ability to have some hidden information in each block.

The virtual file system-specific implementation is also responsible for setting the uio offset field to the offset of the next whole block to be read.

The **vnop\_readdir** entry point can be called from the process environment only.

### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

The readdir subroutine.

The **uio** structure.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, and Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vnop\_readdir\_eofp Entry Point

## **Purpose**

Returns directory entries.

# **Syntax**

int vnop\_readdirr\_eofp (vp, uiop, eofp, crp) struct vnode \*vp; struct uio \*uiop; int \*eofp; struct ucred \*crp:

### **Parameters**

vp Points to the directory vnode to be processed. Points to the uiop structure describing the user's buffer. uiop eofp Points to a word that places the eop structure.

Specifies user's credentials. crp

# **Description**

The vnop\_readdir\_eofp entry point is used to read directory entries. It is similar to vnop\_readdir except that it takes the additional parameter, *eofp*. The location pointed to by the *eofp* parameter should be set to 1 if the readdir request reached the end of the directory. Otherwise, it should be set to 0.

File systems that do not define GFS\_VERSION421 in their gfs flags do not need to supply a vnop readdir eofp entry point.

### **Execution Environment**

The vnop\_readdir\_eofp entry point can be called from the process environment only.

### **Return Values**

Zero Indicates a successful operation.

Nonzero Indicates that the operation failed; return values should be chosen from the /usr/include/sys/errno.h

### **Related Information**

The readdir subroutine.

Virtual File System Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts, and Virtual File System Kernel Extensions Overview.

## vnop\_readlink Entry Point

## **Purpose**

Reads the contents of a symbolic link.

# **Syntax**

```
int vnop_readlink ( vp, uio, crp)
struct vnode *vp;
struct uio *uio;
struct ucred *crp;
```

### **Parameters**

- Points to a virtual node (v-node) structure. The vnop readlink entry point holds this v-node for the duration of the routine.
- Points to a uio structure. This structure contains the information required to read the link. In addition, it uio contains the return buffer for the **vnop\_readlink** entry point.
- Points to the cred structure. This structure contains data that the file system can use to validate access crp permission.

# **Description**

The vnop\_readlink entry point is used by the logical file system to get the contents of a symbolic link, if the file system supports symbolic links. The logical file system finds the v-node (virtual node) for the symbolic link, so this routine simply reads the data blocks for the symbol link.

### **Execution Environment**

The **vnop\_readlink** entry point can be called from the process environment only.

#### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vnop rele Entry Point

## Purpose

Releases a reference to a virtual node (v-node).

# **Syntax**

int vnop rele (vp,) struct vnode \*vp;

### **Parameter**

Points to the v-node.

# **Description**

The vnop\_rele entry point is used by the logical file system to release the object associated with a v-node. If the object was the last reference to the v-node, the vnop\_rele entry point then calls the vn\_free kernel service to deallocate the v-node.

If the virtual file system (VFS) was unmounted while there were open files, the logical file system sets the VFS UNMOUNTING flag in the vfs structure. If the flag is set and the v-node to be released is the last v-node on the chain of the vfs structure, then the virtual file system must be deallocated with the vnop\_rele entry point.

#### **Execution Environment**

The **vnop** rele entry point can be called from the process environment only.

### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

The vn free kernel service.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_remove Entry Point

# **Purpose**

Unlinks a file or directory.

## **Syntax**

```
int vnop_remove ( vp, dvp, name, crp)
struct vnode *vp;
struct vnode *dvp;
char *name;
struct ucred *crp;
```

### **Parameters**

Points to a virtual node (v-node). The v-node indicates which file to remove and is held over the duration of the **vnop\_remove** entry point.

Points to the v-node of the parent directory. This directory contains the file to be removed. The directory's dvp v-node is held for the duration of the **vnop\_remove** entry point.

Identifies the name of the file.

Points to the cred structure. This structure contains data that the file system can use to validate access crp permission.

## **Description**

The vnop\_remove entry point is called by the logical file system to remove a directory entry (or link) as the result of a call to the unlink subroutine.

The logical file system assumes that the **vnop\_remove** entry point calls the **vnop\_rele** entry point. If the link is the last reference to the file in the file system, the disk resources that the file is using are released.

The logical file system ensures that the directory specified by the dvp parameter does not reside in a read-only file system.

### **Execution Environment**

The **vnop\_remove** entry point can be called from the process environment only.

#### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

The unlink subroutine.

The **vnop\_rele** entry point.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop rename Entry Point

# **Purpose**

Renames a file or directory.

## **Syntax**

```
int vnop_rename (srcvp, srcdvp, oldname, destvp, destdvp, newname, crp)
struct vnode * srcvp;
struct vnode * srcdvp;
char * oldname;
struct vnode * destvp;
struct vnode * destdvp;
char * newname;
struct ucred * crp;
```

#### **Parameters**

Points to the virtual node (v-node) of the object to rename. srcvp srcdvp Points to the v-node of the directory where the srcvp parameter resides. The parent directory for the old and new object can be the same. oldname Identifies the old name of the object. Points to the v-node of the new object. This pointer is used only if the new object exists. Otherwise, destvp this parameter is the null character. Points to the parent directory of the new object. The parent directory for the new and old objects can destdvp be the same. Points to the new name of the object. newname Points to the cred structure. This structure contains data that applications can use to validate access crp permission.

## **Description**

The **vnop\_rename** entry point is invoked by the logical file system to rename a file or directory. This entry point provides the following renaming actions:

- Renames an old object to a new object that exists in a different parent directory.
- · Renames an old object to a new object that does not exist in a different parent directory.
- · Renames an old object to a new object that exists in the same parent directory.
- Renames an old object to a new object that does not exist in the same parent directory.

To ensure that this entry point routine executes correctly, the logical file system guarantees the following:

- File names are not renamed across file systems.
- The old and new objects (if specified) are not the same.
- The old and new parent directories are of the same type of v-node.

### **Execution Environment**

The **vnop\_rename** entry point can be called from the process environment only.

#### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

The **rename** subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_revoke Entry Point

## **Purpose**

Revokes all access to an object.

## **Syntax**

```
int vnop_revoke (vp, cmd, flag, vinfop, crp)
struct vnode * vp;
int cmd:
int flag;
caddr_t vinfop;
struct ucred * crp;
```

### **Parameters**

Points to the virtual node (v-node) containing the object. VD Indicates whether the calling process holds the file open. This parameter takes the following values: cmd

> 0 The process did not have the file open.

1 The process had the file open.

The process had the file open and the reference count in the file structure was greater than 1.

Identifies the flags from the file structure. flag

vinfop This parameter is currently unused.

Points to the cred structure. This structure contains data that the file system can use to validate access crp permission.

# **Description**

The **vnop\_revoke** entry point is called to revoke further access to an object.

#### **Execution Environment**

The **vnop\_revoke** entry point can be called from the process environment only.

#### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

The frevoke subroutine, revoke subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vnop\_rmdir Entry Point

## **Purpose**

Removes a directory.

## **Syntax**

```
int vnop_rmdir ( vp, dp, pname, crp)
struct vnode *vp;
struct vnode *dp;
char *pname;
struct ucred *crp;
```

#### **Parameters**

vp Points to the virtual node (v-node) of the directory.
 dp Points to the parent of the directory to remove.
 pname Points to the name of the directory to remove.

crp Points to the cred structure. This structure contains data that the file system can use to validate access

permission.

## **Description**

The **vnop\_rmdir** entry point is invoked by the logical file system to remove a directory object. To remove a directory, the directory must be empty (except for the current and parent directories). Before removing the directory, the logical file system ensures the following:

- The vp parameter is a directory.
- The vp parameter is not the root of a virtual file system.
- The vp parameter is not the current directory.
- The *dp* parameter does not reside on a read-only file system.

**Note:** The *vp* and *dp* parameters' v-nodes (virtual nodes) are held for the duration of the routine.

### **Execution Environment**

The vnop\_rmdir entry point can be called from the process environment only.

### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

#### **Related Information**

The **rmdir** subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_seek Entry Point

## **Purpose**

Validates file offsets.

## **Syntax**

```
int vnop_seek (vp, offsetp, crp)
struct vnode * vp;
offset_t * offp;
struct ucred * crp;
```

### **Parameters**

Points to the virtual node (v-node) of the file. offp Points to the location of the new offset to validate.

crp Points to the user's credential.

## **Description**

Note: The vnop seek Entry Point applies to AIX<sup>®</sup> 4.2 and later releases.

The vnop\_seek entry point is called by the logical file system to validate a new offset that has been computed by the Iseek, Ilseek, and Iseek64 subroutines. The file system implementation should check the offset pointed to by offp and if it is acceptable for the file, return zero. If the offset is not acceptable, the routine should return a non-zero value. EINVAL is the suggested error value for invalid offsets.

File systems which do not wish to do offset validation can simply return 0. File systems which do not provide the vnop\_seek entry point will have a maximum offset of OFF\_MAX (2 gigabytes minus 1) enforced by the logical file system.

#### **Execution Environment**

The **vnop** seek entry point is be called from the process environment only.

### **Return Values**

Indicates success.

Return values are returned the /usr/include/sys/errno.h file to indicate failure. Nonzero

### **Related Information**

# vnop\_select Entry Point

# **Purpose**

Polls a virtual node (v-node) for immediate I/O.

### **Syntax**

```
int vnop_select (vp, correl, e, re, notify, vinfo, crp)
struct vnode * vp;
int correl;
int e;
int re;
int (* notify)();
caddr_t vinfo;
struct ucred * crp;
```

#### **Parameters**

*vp* Points to the v-node to be polled.

correl Specifies the ID used for correlation in the **selnotify** kernel service.

*e* Identifies the requested event.

re Returns an events list. If the v-node is ready for immediate I/O, this field should be set to indicate the

requested event is ready.

notify Specifies the subroutine to call when the event occurs. This parameter is for nested polls.

vinfo Is currently unused.

crp Points to the **cred** structure. This structure contains data that the file system can use to validate access

permission.

## **Description**

The **vnop\_select** entry point is invoked by the logical file system to poll a v-node to determine if it is immediately ready for I/O. This entry point is used to implement the **select** and **poll** subroutines.

File system implementation can support constructs, such as devices or pipes, that support the select semantics. The **fp\_select** kernel service provides more information about select and poll requests.

#### **Execution Environment**

The **vnop\_select** entry point can be called from the process environment only.

#### Return Values

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

The **poll** subroutine, **select** subroutine.

The **fp select** kernel service, **selnotify** kernel service.

# vnop\_setacl Entry Point

# **Purpose**

Sets the access control list (ACL) for a file.

### **Syntax**

```
#include <sys/acl.h>
int vnop_setacl ( vp, uiop, crp)
struct vnode *vp;
struct uio *uiop;
struct ucred *crp;
```

### **Description**

The vnop\_setacl entry point is used by the logical file system to set the access control list (ACL) on a file.

### **Parameters**

vp Specifies the virtual node (v-node) of the file system object.

uiop Specifies the uio structure that defines the storage for the call arguments.

crp Points to the cred structure. This structure contains data that the file system can use to validate access permission.

### **Execution Environment**

The **vnop\_setacl** entry point can be called from the process environment only.

### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure. Valid values include:

**ENOSPC** Indicates that the space cannot be allocated to hold the new ACL information.

Indicates that the effective user ID of the process is not the owner of the file and the process is not **EPERM** 

privileged.

### **Related Information**

The **uio** structure.

The chacl subroutine, chown subroutine, chmod subroutine, statacl subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop setattr Entry Point

# **Purpose**

Sets attributes of a file.

# **Syntax**

```
int vnop_setattr (vp, cmd, arg1, arg2, arg3, crp)
struct vnode * vp;
int cmd;
```

```
int arg1;
int arg2;
int arg3;
struct ucred * crp;
```

### Description

The **vnop\_setattr** entry point is used by the logical file system to set the attributes of a file. This entry point is used to implement the **chmod**, **chownx**, and **utime** subroutines.

The values that the *arg* parameters take depend on the value of the *cmd* parameter. The **vnop\_setattr** entry point accepts the following *cmd* values and *arg* parameters:

Possible cmd Values for the vnop\_setattr Entry Point

Command	V_OWN	V_UTIME	V_MODE
arg1	int flag;	int flag;	int mode;
arg2	int uid;	timestruc_t *atime;	Unused
arg3	int gid;	timestruc_t *mtime;	Unused

**Note:** For **V\_UTIME**, if arg2 or arg3 is NULL, then the corresponding time field, *atime* and *mtime*, of the file should be left unchanged.

### **Parameters**

vp cmd Points to the virtual node (v-node) of the file.

Defines the setting operation. This parameter takes the following values:

#### V OWN

Sets the user ID (UID) and group ID (GID) to the UID and GID values of the new file owner. The *flag* argument indicates which ID is affected.

#### **V UTIME**

Sets the access and modification time for the new file. If the *flag* parameter has the value of **T\_SETTIME**, then the specific values have not been provided and the access and modification times of the object should be set to current system time. If the **T\_SETTIME** value is not specified, the values are specified by the *atime* and *mtime* variables.

#### V\_MODE

Sets the file mode.

The /usr/include/sys/vattr.h file contains the definitions for the three command values.

arg1, arg2, arg3

Specify the command arguments. The values of the command arguments depend on which command calls the **vnop\_setattr** entry point.

crp

Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

### **Execution Environment**

The vnop\_setattr entry point can be called from the process environment only.

### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

The **chmod** subroutine, **chownx** subroutine, **utime** subroutine.

Virtual File System Kernel Extensions Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vnop\_setxacl Entry Point

### **Purpose**

Sets the access control list (ACL) for a file system object. This is an advanced interface compared to **vnop\_setacl** and provides for ACL-type-based operations.

# **Syntax**

# **Description**

The **vnop\_setxacl** entry point sets the access control list (ACL) on a file. It is an advanced version of **vnop\_setacl** interface and provides for ACL-type-based operations. This interface can also be used to manage special bits in mode word (such as SUID, SGID and SVTX) in case the ACL type does not support these bits through ACL. For more details about the various ACL types, refer to *AIX Version 7.1 Security*.

### **Parameters**

vp :	Specifies the virtual node (	(v-node) of the file system (	object for which the ACL needs
------	------------------------------	-------------------------------	--------------------------------

to be set.

acl\_type Specifies the ACL type of the ACL information that needs to be set for the file

system object.

Note: If the underlying physical file system does not support the ACL type being

requested, the system could return an error.

acl\_len Pointer to a length variable. The space pointed to is used as an input, as well as

output, parameter. As input, the value will indicate the size of buffer *uiop*. When the call returns, this space holds the actual length of the ACL (true for when the call is

successful or when the call fails with errno set to ENOSPC).

ctl\_flags This 64-bit bit mask provides for control over the ACL setting and for any future

variations in the interface. The following flag values have been defined:

#### SET\_MODE\_S\_BITS

Indicates that the *mode\_info* value is set by the caller and the ACL put operation must consider this value to complete the ACL put operation.

#### SET ACL

Indicates that the ACL arguments point to valid ACL data that must be considered while the ACL put operation is being performed.

Note: Both of the preceding values can be specified by the caller by ORing the two

Specifies the **uio** structure that defines the storage for the call arguments.

uiop

mode\_info This value indicates any mode word information that needs to be set for the file

> system object as part of this ACL put operation. When mode bits are altered by specifying the **SET\_MODE\_S\_BITS** flag (in *ctl\_flags*), the entire ACL put operation

will fail if the caller does not have the required privileges.

Points to the **cred** structure. This structure contains data that the file system can crp

use to validate access permission.

### **Execution Environment**

The **vnop\_setxacl** entry point can be called from the process environment only.

### **Return Values**

Upon successful completion, the vnop\_setxacl entry point returns 0. Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

**EPERM** Indicates that the effective user ID of the process is not authorized to change the ACL on

the specified file system object.

**EINVAL** Invalid operation. File system might not support the ACL type being set.

**Note:** This list of error numbers is not complete and is dependent on the particular physical file system implementation supporting the ACL.

### **Related Information**

List of Virtual File System Operations.

# vnop strategy Entry Point

# **Purpose**

Accesses blocks of a file.

# **Syntax**

```
int vnop_strategy ( vp, bp, crp)
struct vnode *vp;
struct buf *bp;
struct ucred *crp;
```

# **Description**

Note: The vnop\_strategy entry point is not implemented in Version 3.2 of the operating system.

The vnop strategy entry point accesses blocks of a file. This entry point is intended to provide a block-oriented interface for servers for efficiency in paging.

### **Parameters**

- Points to the virtual node (v-node) of the file.
- Points to a buf structure that describes the buffer. bp
- Points to the cred structure. This structure contains data that applications can use to validate access crp permission.

### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

# vnop\_symlink Entry Point

### **Purpose**

Creates a symbolic link.

# **Syntax**

```
int vnop symlink (vp, linkname, target, crp)
struct vnode *vp;
char *linkname;
char *target;
struct ucred *crp;
```

# **Description**

The **vnop symlink** entry point is called by the logical file system to create a symbolic link. The path name specified by the linkname parameter is the name of the new symbolic link. This symbolic link points to the object named by the target parameter.

### **Parameters**

Points to the virtual node (v-node) of the parent directory where the link is created.

Points to the name of the new symbolic link. The logical file system guarantees that the new link linkname

does not already exit.

Points to the name of the object to which the symbolic link points. This name need not be a fully target

qualified path name or even an existing object.

Points to the cred structure. This structure contains data that the file system can use to validate crp

access permission.

### **Execution Environment**

The **vnop\_symlink** entry point can be called from the process environment only.

### **Return Values**

0 Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

The **symlink** subroutine.

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.

## vnop\_unmap Entry Point

# **Purpose**

Unmaps a file.

# **Syntax**

```
int vnop_unmap ( vp, flag, crp)
struct vnode *vp;
ulong flag;
struct ucred *crp;
```

# **Description**

The **vnop unmap** entry point is called by the logical file system to unmap a file. When this entry point routine completes successfully, the use count for the memory object should be decremented and (if the use count went to 0) the memory object should be destroyed. The file system implementation is required to perform only those operations that are unique to the file system. The logical file system handles virtual-memory management operations.

### **Parameters**

Points to the v-node (virtual node) of the file. vp

Indicates how the file was mapped. This flag takes the following values: flag

SHM RDONLY

The virtual memory object is read-only.

SHM COPY

The virtual memory object is copy-on-write.

Points to the cred structure. This structure contains data that the file system can use to validate access crp permission.

### **Execution Environment**

The **vnop\_unmap** entry point can be called from the process environment only.

### **Return Values**

Indicates success.

Nonzero return values are returned from the /usr/include/sys/errno.h file to indicate failure.

### **Related Information**

Virtual File System Overview, Virtual File System Kernel Extensions Overview, Logical File System Overview, Understanding Virtual Nodes (V-nodes) in AIX® Version 7.1 Kernel Extensions and Device Support Programming Concepts.
