

DIGITAL Alpha VME 5/352 and 5/480 Single-Board Computers

Technical Reference

Order Number: EK-VME54-TM. A01

This manual discusses DIGITAL Alpha VME 5/352 and 5/480 single-board computer (SBC) address mapping, VME interface, system interrupts, and system registers.

Revision/Update Information:

This is a new manual.

First Printing, February 1998

Digital Equipment Corporation assumes not responsibility for any errors that might appear in this document.

The software described in this document is furnished under license and may be used or copied only in accordance with the terms of such license. No responsibility is assumed for the use or reliability of software or equipment that is not supplied by Digital Equipment Corporation or its affiliated companies.

Restricted Rights: Use, duplication, or disclosure by the U.S. Government is subject to restrictions as set forth in subparagraph (c) (1) (ii) of the Rights in Technical Data and Computer Software clause at DFARS 252.227-7013.

FCC Notice:

This equipment has been tested and found to comply with the limits for a Class A digital device, pursuant to Part 15 of the FCC Rules. These limits are designed to provide reasonable protection against harmful interference when the equipment is operated in a commercial environment. This equipment generates, uses, and can radiate radio frequency energy and, if not installed and used in accordance with the instruction manual, may cause harmful interference to radio communications. Operation of this equipment in a residential area is likely to cause harmful interference, in which case the user will be required to correct the interference at his own expense.

Warning!

This is a Class A product. In a domestic environment this product may cause radio interference in which case the user may be required to take adequate measures.

Achtung!

Dieses ist ein Gerät der Funkstörgrenzwertklasse A. In Wohnbereichen können bei Betrieb dieses Gerätes Rundfunkstörungen auftreten, in welchen Fällen der Benutzer für entsprechende Gegenmaßnahmen verantwortlich ist.

Attention!

Ceci est un produit de Classe A. Dans un environnement domestique, ce produit risque de créer des interférences radioélectriques, il appartiendra alors à l'utilisateur de prendre les mesures spécifiques appropriées.

Canadian EMC Notice:

"This Class [A] digital apparatus meets all requirements of the Canadian Interference-Causing Equipment Regulations."

"Cet appareil numérique de la class [A] respecte toutes les exigences du Règlement sur le matériel brouilleur du Canada."

Preface

Purpose of this Manual

This manual introduces the DIGITAL Alpha VME 5/352 and 5/480 single-board computer (SBC) functional components and discusses technical details, including address mapping, the VME interface, system interrupts, and system registers.

Intended Audience

This manual is for OEM system integrators who are designing and building a DIGITAL Alpha VME 5/352 or 5/480 SBC into specific application systems. These systems may range in scope from a single Alpha VME 5/352 or 5/480 SBC to highly complex multiprocessor systems that include a variety of hardware.

This manual assumes that readers have prerequisite knowledge and experience with the following:

- System design
- VMEbus design and specifications
- System-level programming

Structure of this Manual

This manual consists of five chapters and an index organized as follows:

- Chapter 1, Introduction, describes the functional components associated with the DIGITAL Alpha VME 5/352 and 5/480 SBCs.
- Chapter 2, Address Mapping, provides an address space overview and describes the implementation PCI memory space.
- Chapter 3, VME Interface, discusses the VME interface, including VME address mapping, initialization, and usage.
- Chapter 4, System Interrupts, provides an overview of system interrupts, identifies interrupts handled by the various controllers and chips, and module resets.
- Chapter 5, System Registers, describes system registers associated with the Ethernet controller, interval timer, module, SCSI controller, SIO chip, time-of-year (TOY) clock, VME interface, and watchdog timer.

Conventions

This section defines terminology, abbreviations, and other conventions used in this manual.

Abbreviations

- Register access

The following list describes the register bit and field abbreviations:

Bit/Field Abbreviation	Description
MBZ (must be zero)	Bits and fields specified as MBZ must be zero.
RO (read only)	Bits and fields specified as RO can be read but not written.
RW (read/write)	Bits and fields specified as RW can be read and written.
SBZ (should be zero)	Bits and fields specified as SBZ should be zero.
WO (write only)	Bits and fields specified as WO can be written but not read

- Binary multiples

The abbreviations K, M, and G (kilo, mega, and giga) represent binary multiples and have the following values:

Abbreviation	Binary Multiple
K	2^{10} (1024)
M	2^{20} (1,048,576)
G	2^{30} (1,073,741,824)

For example:

2 KB	= 2 kilobytes	= 2×2^{10} bytes
4 MB	= 4 megabytes	= 4×2^{20} bytes
8 GB	= 8 gigabytes	= 8×2^{30} bytes

Addresses

Unless otherwise noted, addresses and offsets are hexadecimal values.

Bit Notation

Multiple-bit fields can include contiguous and noncontiguous bits contained in angle brackets (<>). Multiple contiguous bits are indicated by a pair of numbers separated by a colon (:). For example, <9:7,5,2:0> specifies bits 9, 8, 7, 5, 2, 1, and 0. Similarly, single bits are frequently indicated with angle brackets. For example, <27> specifies bit 27.

Caution

Cautions indicate potential damage to equipment or loss of data.

Data Field Size

The term INT nn , where nn is one of 2, 4, 8, 16, 32, or 64, refers to a data field of nn contiguous NATURALLY ALIGNED bytes. For example, INT4 refers to a NATURALLY ALIGNED longword.

Data Units

The following data unit terminology is used throughout this manual.

Term	Words	Bytes	Bits	Other
Byte	1/2	1	8	–
Word	1	2	16	–
Longword	2	4	32	Longword
Quadword	4	8	64	2 Longwords
Octaword	8	16	128	2 Quadwords
Hexword	16	32	256	2 Octawords

Keyboard Keys

The following keyboard key conventions are used throughout this manual.

Convention	Example
Control key sequences are represented as Ctrl/ x . Press Ctrl while you simultaneously press the x key	Ctrl/C
In plain text, key names match the name on the actual key.	Return key
In tables, key names match the name of the actual key and appear in square brackets ([]).	[Return]

Examples

Prompts, input, and output in examples are shown in a monospaced font. Interactive input is differentiated from prompts and system output with bold type. For example:

```
>>> echo This is a test.[Return]
This is a test.
```

Ellipsis points indicate that a portion of an example is omitted.

Names and Symbols

The following table lists typographical conventions used for names of various items throughout this manual.

Items	Example
Bits	sysBus <32:2>
Commands	boot command
Command arguments	<i>address</i> argument
Command options	-sb option
Environment variables	AUTO_ACTION
Environment variable values	HALT
Files and pathnames	/usr/foo/bar
Pins	LIRQ pin
Register symbols	VIP_ICR register
Signals	iogrant signal
Variables	<i>n, x, mydev</i>

Note

Notes emphasize particularly important information.

Numbering

Numbers are decimal or hexadecimal unless otherwise indicated. The prefix 0x indicates a hexadecimal number. For example, 19 is decimal, but 0x19 and 0x19A are hexadecimal (see also Addresses). Otherwise, the base is indicated by a subscript; for example, 100² is a binary number.

Ranges and Extents

Ranges are specified by a pair of numbers separated by two periods (..) and are inclusive. For example, a range of integers 0..4 includes the integers 0, 1, 2, 3, and 4.

Extents are specified by a pair of numbers in angle brackets (<>) separated by a colon (:) and are inclusive.

Bit fields are often specified as extents. For example, bits <7:3> specifies bits 7, 6, 5, 4, and 3.

Register and Memory Figures

Register figures have bit and field position numbering starting at the right (low-order) and increasing to the left (high-order).

Memory figures have addresses starting at the top and increasing toward the bottom.

Syntax

The following syntax elements are used throughout this manual. Do not type the syntax elements when entering information.

Element	Example	Description
[]	[-file filename]	The enclosed items are optional.
	- + =	Choose one of two or more items. Select one of the items unless the items are optional.
{ }	{ - + = }	You must specify one (and only one) of the enclosed items.
()	(a,b,c)	You must specify the enclosed items together.
...	arg...	You can repeat the preceding item one or more times.

UNPREDICTABLE and UNDEFINED

This manual uses the terms UNPREDICTABLE and UNDEFINED. Their meanings are different and must be carefully distinguished.

UNPREDICTABLE results or occurrences do not disrupt the basic operation of the processor. The processor continues to execute instructions in its normal manner. In contrast, UNDEFINED operations can halt the processor or cause it to lose information.

Introduction

This chapter introduces the functional components associated with the DIGITAL Alpha VME 5/352 and 5/480 SBCs. The chapter begins with an overview (Section 1.1) and then briefly describes the following:

- 21164 Alpha microprocessor chip, Section 1.2
- 21172 core logic chipset, Section 1.3
- Bcache subsystem, Section 1.4
- Memory subsystem, Section 1.5
- SRAM, Section 1.6
- Clock interface, Section 1.7
- PCI interface, Section 1.8
- Nbus interface, Section 1.9
- VME interface, Section 1.10

1.1 Functional Component Overview

Figure 1–1 identifies the functional components of the Alpha VME 5/352 and 5/480 SBCs. The Alpha VME 5/352 and 5/480 CPU modules are based on the 21164 Alpha microprocessor, and run at 352 MHz and 480 MHz, respectively. The 21172 core logic chipset consists of the 21172–CA control, I/O interface, and address (CIA) chip and four 21172–BA data switch (DSW) chips. Nine SRAMs provide 2 MB of Bcache and two or four main memory DIMMs provide from 16 to 512 MB of EDO memory. The system clock uses a phase lock loop (PLL)/buffer circuit to provide SYSCLK signals to 10 system components at 32 MHz.

The CPU module interfaces with the I/O module through a 32-bit PCI bus. As Figure 1–1 shows, the I/O module provides a:

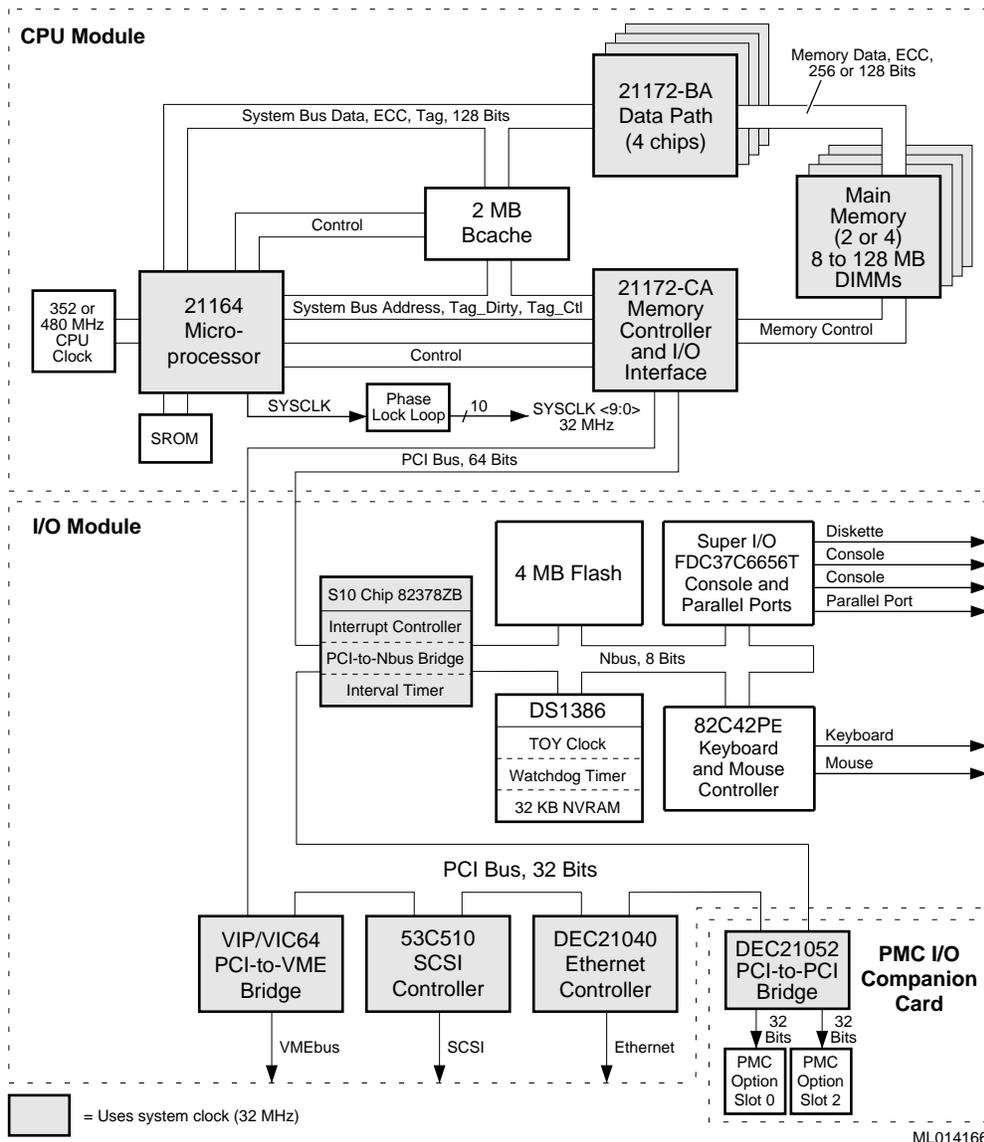

- PCI-to-VME bridge (DC7407 VIP and VIC64), which provides an interface to the VMEbus
- PCI-to-SCSI controller (53C810), which provides an interface to SCSI devices
- PCI-to-Ethernet controller (21040), which provides a network interface
- PCI-to-Nbus bridge (82378ZB), which provides access to the system's 8-bit Nbus and includes interrupt controller and interval timer support
- PCI–32 interface to an optional PMC I/O companion card

The I/O module's Nbus is a resource bus that is based on the ISA bus. The Nbus handles the read and write cycles for the following:

- 4M of flash ROM
- Super I/O chip (FDC37C6656T) resources, which include console and parallel ports and a diskette drive controller
- TOY clock, watchdog timer, and NVRAM chip (DS1386) resources
- Keyboard and mouse controller (82C42PE)

The I/O module interfaces to an optional PMC I/O companion card through the 32-bit PCI bus. The PMC I/O companion card uses a DEC 21052 PCI-to-PCI bridge to provide access to two PMC option slots. This optional card also provides keyboard, mouse, and diskette drive connectors.

Figure 1-1 Alpha VME 5/352 and 5/480 Functional Components

1.2 21164 Alpha Microprocessor

The Alpha VME 5/352 and 5/480 SBCs are based on the 21164 Alpha microprocessor, which is a superscalar pipelined processor manufactured using 0.35 μm CMOS technology. It is packaged in a 499-pin IPGA carrier.

The 21164 microprocessor can issue four Alpha instructions in a single cycle, thereby minimizing the average cycles per instruction (CPI). A number of low-latency and/or high-throughput features in the instruction issue unit and the onchip components of the memory subsystem further reduce the average CPI.

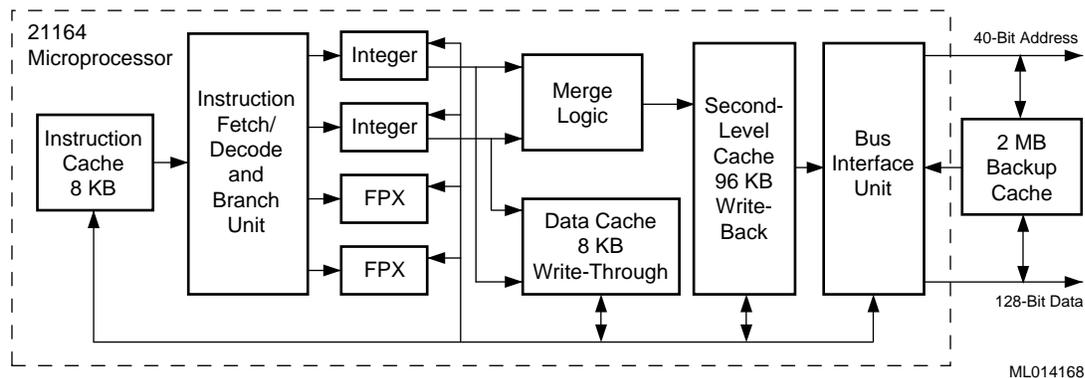

The 21164 microprocessor and associated PALcode implements IEEE single-precision and double-precision, VAX F_floating and G_floating data types, and supports longword (32-bit) and quadword (64-bit) integers. Byte (8-bit) and word (16-bit) support is provided by byte-manipulation instructions. Limited hardware support is provided for the VAX D_floating data type. Partial hardware implementation is provided for the architecturally optional FETCH and FETCH_M instructions.

Other features of the microprocessor include:

- An onchip, demand-paged memory-management unit with a translation buffer
- Two onchip, high-throughput pipelined floating-point units, capable of executing both DIGITAL and IEEE floating-point data types
- An onchip, 8 KB virtual instruction cache (Icache) with 7-bit ASNs (MAX_ASN=127)
- An onchip, dual-read-ported, 8 KB data cache (Dcache)
- An onchip, write buffer with six 32-byte entries
- An onchip, 96 KB, 3-way, set-associative, write-back, second level (level 2) mixed instruction and data cache
- A 128-bit data bus with onchip parity and error correction code (ECC) support
- Support for an external third level (level 3) synchronous 2 MB backup cache (Bcache)
- An internal clock generator providing a high-speed clock used by the 21164 microprocessor, and a pair of programmable system clocks for use by the CPU module
- Onchip performance counters to measure and analyze CPU and system performance
- An Icache test interface to support chip and module level testing
- A 3.3 V external interface and 2.5 V core power for reduced power consumption

Figure 1–2 shows the microprocessor's functional units and caches in a functional block diagram.

Figure 1–2 21164 Alpha Microprocessor Functional Block Diagram

For more detailed information on the microprocessor, see the *Digital Semiconductor 21164 Alpha Microprocessor Hardware Reference Manual*.

1.3 21172 Core Logic Chipset

The DIGITAL 21172 core logic chipset supports the 21164 Alpha microprocessor in high-performance uniprocessor systems. The chipset includes an interface to the 64-bit peripheral component interconnect (PCI) bus, and associated control and data paths for the 21164 microprocessor chip, memory, and level 3 Bcache.

Sections 1.3.1 and 1.3.2 discuss the chipset components and features. For more detailed information on the 21172 core logic chipset, see the *Digital Semiconductor 21172 Core Logic Chipset Technical Reference Manual*.

1.3.1 Chipset Components

The chipset consists of:

- A control, I/O interface, and address (CIA) chip – 21172-CA chip

The CIA chip is a 388-pin plastic ball grid array (PBGA) package that provides control functions for main memory, a bridge to the 64-bit PCI bus, and control functions for the DSW chips and part of the I/O data path.

- Four data switch (DSW) chips – 21172-BA chips

The DSW chips are 208-pin plastic quad flat pack (PQFP) packages that provide bidirectional data paths between the 21164 microprocessor, main memory, Bcache, the CIA chip, and part of the I/O data path. The majority of the DSW logic consists of data buffers and multiplexers. Using two encoded control fields, the CIA chip directs data flow to and from the DSW chips.

1.3.2 Chipset Features

The chipset includes the majority of functions required to develop high performance systems that require minimum discrete logic on the module. Features include:

- Support for the 21164 Alpha microprocessor chip
- A 64-bit, ECC-protected data path (IOD bus) between the CIA and DSW chips
- A 128-bit ECC-protected data path (system bus) between the 21164 and DSW chips
- A 256-bit ECC-protected memory data path (memory bus) between the DSW chips and memory
- A 32 MHz system bus interface
- Support for 2 MB of write-back, ECC-protected, level 3 Bcache using the flush cache coherency protocol
- Support for 16 to 512 MB of EDO memory
- PCI bus support that includes 64-bit multiplexed address and data paths, 64-bit PCI address handling, and scatter-gather mapping
- 32 MHz PCI clock frequency
- DSW chips that provide a victim buffer for read miss/victim transitions

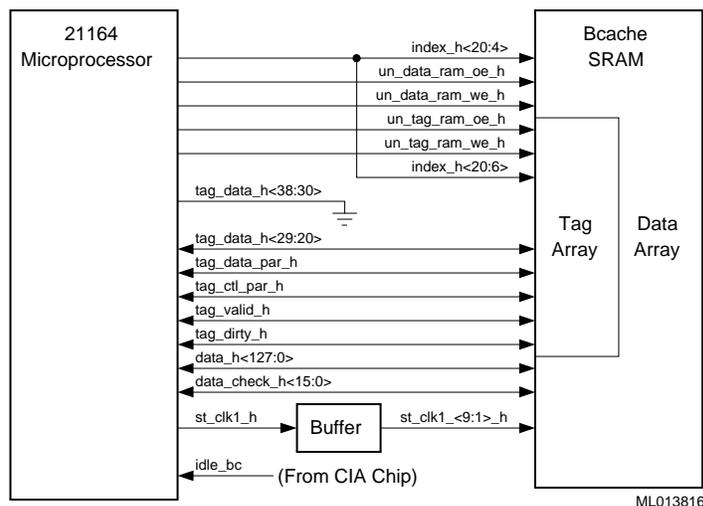

1.4 Bcache Subsystem

The DIGITAL Alpha VME 5/352 and 5/480 SBCs provides 2 MB of direct mapped Bcache. The Bcache is populated with nine 9 nanosecond, 64K-bit X 36-bit synchronous static random access memories (SRAMs). Bcache features include:

- A block size of 64 bytes
- System bus Bcache private read/write transfer rate of 700 MB/s
- ECC protection
- Use of the flush cache coherency protocol as described in the *Digital Semiconductor 21164 Alpha Microprocessor Hardware Reference Manual*

The 21164 Alpha microprocessor controls the level 3 Bcache array as shown in Figure 1-3.

Figure 1–3 Level 3 Bcache Array

1.5 Memory Subsystem

The Alpha VME 5/352 and 5/480 SBCs support two or four dynamic random access memory (DRAM) DIMMs for up to a total of 512 MB of 60 nanosecond, EDO main memory. The memory resides in a single bank. For a listing of valid DIMM combinations, see the *DIGITAL Alpha VME 5/353 and 5/480 Single-Board Computers User Manual*.

Quadword error checking and correction (ECC) is supported on the memory and system buses. The 21172 core logic chipset controls and routes all CPU-to-memory caching and PCI direct memory access (DMA) operations. The DSW and CIA components of the chipset provide a high-speed memory data path that has a width of either 128 or 256 bits, depending on the mode in which the SBC is operating. When you use two DIMMs, the SBC operates in 128-bit mode; when you use four DIMMs the SBC operates in 256-bit mode. The memory bus bandwidth in 128-bit mode is 210 MB/s, while the bandwidth in 256-bit mode is 355 MB/s.

The memory subsystem optimizes its cache read miss with victim write cycle to improve memory and system bus bandwidth. The optimizations are achieved by partitioning the memory row and column addressing such that the read miss row and victim row addresses match.

The cache read miss cycle begins when the 21164 Alpha microprocessor recognizes a cache read miss with victim. When a read miss with victim is identified, the microprocessor instructs the CIA chip to take the victim and then get the read miss data. The CIA chip places the victim data in a DSW buffer while initiating a memory read cycle (RAS–CAS–RAS). The CIA and DSW chips then supply the read data to the microprocessor and cache then write the victim data to memory (CAS–CAS). The resulting memory cycle — CAS – RAS (read 32 bytes) – RAS (read 32 bytes) – RAS (write 32 bytes) – RAS (write 32 bytes) — completes in 360 ns or 355 MB/s.

1.6 SROM

The SROM for the Alpha VME 5/352 and 5/480 SBCs contains 8 KB of code that is loaded into the Alpha 21164 microprocessor's Icache serially when the system powers up or during a reset. Execution is passed to this code in PAL mode. SROM initialization is explained in detail in the *DIGITAL Alpha VME 5/352 and 5/480 Single-Board Computers User Manual*.

The SROM is socketed to allow future firmware upgrades.

1.7 Clock Interface

The CPU clock circuit used by the Alpha VME 5/352 and 5/480 SBCs multiplies a 16 MHz clock frequency by 22 or 30 and buffers the results, supplying the Alpha 21164 microprocessor with a 352 MHz or 480 MHz clock speed. The microprocessor divides the input value 352 or 480 by 11 or 15, respectively, to generate the system clock.

The 21164 system clock signal (SYSCLK) drives a phase lock loop (PLL)/buffer circuit. That circuit, in turn, generates 10 copies of the 32 MHz SYSCLK signal for the 21172 core logic chipset components and all PCI devices.

The 21172 core logic chipset generates its own 1x and 2x clock signals on each DSW and CIA chip.

1.8 PCI Interface

The PCI interface consists of a PCI bus that serves as the base of the I/O subsystem, connecting all of the system's PCI devices. The I/O subsystem consists of the 21172 core logic CIA and DSW chips and the following PCI devices:

- Ethernet controller
- SCSI controller
- PMC I/O companion card
- Nbus interface
- VME interface

Sections 1.8.1 to 1.8.3 briefly discuss Ethernet, SCSI, and PCI Expansion Card support. For introductions to the Nbus and VME interfaces, see Sections 1.9 and 1.10.

1.8.1 Ethernet Controller

The Ethernet controller for the Alpha VME 5/352 and 5/480 SBCs is based on the DECchip 21040-AA. This chip keeps processor intervention in local area network (LAN) control to a minimum. The chip behaves:

- As a bus slave when communicating with the PCI bus to gain access to configuration and control/status registers
- As a bus master when communicating with memory

The Ethernet controller handles the following types of cycle termination:

- Target-initiated retry
- Abort
- DEVSEL abort

Target-aborted terminations cause an interrupt.

The physical connection to the network is through the Ethernet 10BASE-T twisted-pair connector located on the front panel of the CPU and I/O subassembly.

The Ethernet ID address for the Alpha VME 5/352 or 5/480 SBC assembly is stored in a 20-pin socketed PLCC.

For more information on programming and using the DECchip 21040-AA, see the *DECchip 21040-AA Specification*.

1.8.2 SCSI Controller

The SCSI controller for the Alpha VME 5/352 and 5/480 SBCs is based on the Symbios 53C810 chip. This controller allows you to attach up to seven SCSI devices to your SBC.

The primary breakout module (5424663) provides an interface to a standard SCSI cable. This module brings the SCSI bus to a standard 50-pin SCSI IDC connector pinning for direct connection to an unshielded SCSI cable. A 6-pin jumper block on the module controls SCSI termination as follows:

- Enables SCSI termination when the jumper is set across pins 1 and 3
- Disables SCSI termination when the jumper is set across pins 3 and 5

The controller can affect high-level SCSI operations with very little intervention from the processor. The controller accomplishes this through its low-level register interface or by applying Symbios SCSI scripts.

Once the controller is configured in PCI address space, programming of the Symbios 53C810 chip is compatible with the Symbios 53C720 chip.

For more information on programming the Symbios 53C720 chip, see the chip's programming guide.

1.8.3 PMC I/O Companion Card

The optional PMC I/O companion card provides a 21052 PCI-to-PCI bridge chip and two sets of PMC connectors for adding one double-width or two single-width PMC option modules. One of the PMC connector sets includes a third connector that allows I/O access through the P2 connector.

PCI bus arbitration supports two PMC devices with up to four interrupt request lines. The PCI clock is driven from the CPU and I/O subassembly at a frequency of 32 MHz. The card connectors provide 3V and 5V supply voltages. Although you can have mixed supply voltages between cards, the PCI bus signaling voltage must be configured to 5V when the card is installed.

1.9 Nbus Interface

The Nbus interface is a simple nonmultiplexed resource bus that is based on the ISA bus and supports 8-bit data transfers and 16-bit addressing. This bus provides an interface to the PCI bus through an Intel System I/O chip (82378ZB). The interface translates PCI I/O references to the Nbus into simple read and write cycles for resources attached to the Nbus lines. Such resources include the system's:

- Interrupt controllers
- Flash ROM
- TOY clock
- Watchdog timer
- NVRAM
- Interval timer
- Keyboard and mouse controller
- Super I/O chip

1.9.1 Interrupt Controllers

Most interrupts on Alpha VME 5/352 and 5/480 SBCs are routed through the following interrupt controllers:

- Xilinx interrupt controller
- VIC64 chip system interrupt controller
- SIO chip (82378ZB) programmable interrupt controller

The Xilinx interrupt controller handles CPU interrupts. This controller consists of four interrupt mask registers that generate CPU interrupt request signals.

The VIC64 chip interrupt controller handles VMEbus interrupts. It controls two external/system interrupt sources: DC7407 status and DC7407 errors. Each of these sources has an associated interrupt control register (ICR) that allows the interrupt to be programmed with an interrupt priority level (IPL) or disabled.

Use of the VIC64 chip in Alpha VME 5/352 and 5/480 SBCs as an interrupt controller is modified slightly by the operation of the DC7407, the SIO chip, and the interrupt/mask registers.

The SIO chip interrupt controller delivers interrupts from the mouse, keyboard, and Super I/O chip (FDC37C6656T) to the interrupt/mask register.

For more information about the interrupt controllers and the handling of system interrupts, see Chapter 4.

1.9.2 Flash ROM

The Alpha VME 5/352 and 5/480 SBCs have a total of 4 MB of electrically erasable and writable flash ROM. The flash ROM is segmented into 1 MB windows, using bits <1:0> of a module control register. The system console firmware is pre-written into the first 512 KB, providing you with 3.5 MB of additional space to use for your application.

To protect the contents of the flash ROM from unauthorized or accidental updates, you must close DIP Switch 2 on the I/O module before enabling write operations. That switch must always be open unless you are updating the flash ROM. (The state of the switch is stored in Flash Switch bit <3> of the module control register.) Independent of the state of the switch, you can overwrite the setting in the software to enable automatic updates.

1.9.3 TOY Clock

The Dallas Semiconductor DS1386 chip provides the SBC's time-of-year (TOY) clock functionality. This chip also supports the watchdog and SRAM functionality as nonvolatile random access memory (NVRAM).

Note

The Alpha VME 5/352 and 5/480 SBCs do not support the DS1386 chip's alarm features.

The TOY clock maintains the system's time: year, month, date, day, hour, minute, second, 110th of a second, and 1/100th of a second. The clock corrects the date for months with fewer than 31 days and for leap years. In addition, the clock can maintain the time in 24-hour or 12-hour AM/PM format.

The square wave output of the chip generates a fixed 1024 Hz interval and time-keeping accuracy is better than +/- minute/month at 25° C.

The clock maintains time in the absence of Vcc by using an internal lithium (less than 0.5 grams) energy cell that has an active life of at least 10 years. In addition, internally the clock protects against spurious accesses during power transitions. Some applications may require the TOY clock and NVRAM to operate from an external uninterruptable power supply (UPS). The Alpha VME 5/352 and 5/480 SBCs have an onboard switch (J3 switch 1) to allow a connection to the 5 V standby connection (5VSTDBY) on the VMEbus. When Switch 1 is closed, the VME 5VSTDBY is connected to the TOY supply through isolation diodes.

The chip is socketed to allow:

- Replacement when the internal power source is no longer functional
- Physical removal of the NVRAM

The TOY clock registers are updated every 0.01 seconds. You gain access to the clock to examine or set the current time by using the console **date** command (see the *DIGITAL Alpha VME 5/352 and 5/480 Single-Board Computers User Manual*).

1.9.4 Watchdog Timer

The watchdog timer resides on the Dallas Semiconductor DS1386 chip. The watchdog timer allows hardware to bring the system back to a known state when a software failure occurs.

An application can initialize the watchdog timer with a value in the range 0.01 to 99.9 seconds. If left unaccessed, the timer decrements towards 0. If the timer reaches 0, the watchdog timer halts the system (jump to Halt entry in firmware) and then forces the module hardware to be reset (some 300 ms later). The application can maintain the module by periodically accessing the watchdog timer registers. When you access these registers, the watchdog timer resets back to the initialization value. Therefore, as long as the worst-case time between watchdog timer access is less than the programmed timeout value, the module functions normally.

The Alpha VME 5/352 and 5/480 SBCs indicate the status of the on-board watchdog timer with the signal WD_STATUS_OC on pin C6 of the VME P2 connector. This signal is driven low when an on-board watchdog timer expires. The device that drives the signal is a 74LS05 open-collector inverter. This device is capable of sinking the signal a maximum of 8 mA (IOL). You can pull up the WD_STATUS_OC signal to the 5 V rail by using a 2 K Ω resistor and setting the primary breakout module jumper across pins 4 and 6 (default). To disconnect the resistor from the 5 V rail, set the jumper across pins 2 and 4.

In addition to the hardware support for watchdog timer operation, you can configure the firmware to dispatch to user code or continue with its default reset action on watchdog timeout. The firmware can detect the expiration of the watchdog timer during a reset operation by examining the hardware reset reason register. The jump to the Halt code just before the reset enables the firmware to record a snapshot of the processor's state before the hardware reset is complete.

1.9.5 NVRAM

Within the TOY clock, the Alpha VME 5/352 and 5/480 SBCs offer just under 32 KB of on-board SRAM that is backed up by battery. The RAM is provided by the Dallas Semiconductor DS1386 chip and is held nonvolatile by a built-in lithium battery source.

The nonvolatile RAM (NVRAM) is accessible for read and write operations in Nbus space. The DS1386 chip contains 32 KB read/write byte elements. The lowest 14 of these bytes have special register functions for operation of the TOY clock and watchdog timer. You can use the remaining bytes, 32754 bytes, as general-purpose byte-wide read/write RAM.

1.9.6 Interval Timer

The interval timer for the Alpha VME 5/352 and 5/480 SBCs is based on the 82C54 chip. On power up, the 82C54 chip is in an undefined state and must be initialized before being used. For information on timers, timer modes, or how to use the chip, see Section 5.4.6.

1.9.7 Keyboard and Mouse Controller

The keyboard and mouse controller is provided by an Intel 82C42PE single-chip microcomputer. The controller is programmed to be IBM PC/AT compatible and can drive the keyboard and PS/2 type mouse supported by DECpc systems. The keyboard and mouse ports are female 6-pin mini-DIN, PS/2 type connectors. The controller is programmed to allow either device to operate in either port.

1.9.8 Super I/O Chip

The FDC37C665GT Super I/O chip (not to be confused with the standard I/O, or SIO, chip) supports serial-line port channels A and B (16550 UARTS) and a parallel port. It provides first-in-first-out (FIFO) data access for the serial ports and EPP/ECP modes for the parallel port.

The Alpha VME 5/352 and 5/480 SBCs use channel A for the console. The firmware configures this channel as an asynchronous line, using baud rate, parity, data bit, and stop bit configuration data that you define and is stored in NVRAM. If NVRAM does not contain valid data on power-up, the SBC configures channel A with defaults of 9600 baud, no parity, eight bits, and one stop bit.

The system firmware does not commit or initialize channel B.

1.10 VME Interface

The PCI-to-VME interface for the Alpha VME 5/352 and 5/480 SBCs conforms to the IEC 821, IEEE1014–1987, and D64 sections of IEEE1014 Rev.D (draft) standards. The interface is implemented using the following components:

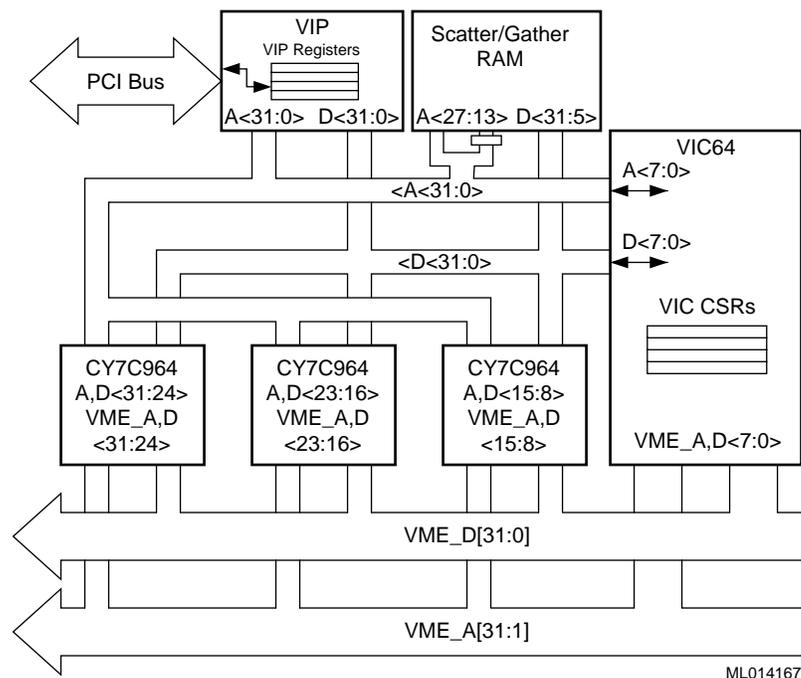

- VIP ASIC (DC7047B) chip
- The Cypress Semiconductor VIC64 VMEbus interface chipset
- Three CY7C964 bus interface chips
- Static scatter-gather RAM for address mapping
- Support logic implemented with programmable logic devices (PLDs)

The VIP/VIC64 chip combination accepts and generates VMEbus D08, D16, D32, and D64 data transfers and protocols. The chip combination supports addressing modes A16, A24, and A32 as a master or slave on the VMEbus.

The VIP chip uses information stored in the scatter-gather RAM to perform big-to-little endian data translation (byte swapping) and address mapping when data moves to and from the VMEbus.

Figure 1–4 shows the interface components and the address and data paths between them.

Figure 1–4 PCI-to-VME Interface Components

ML014167

1.10.1 VIP Chip

The VIP chip controls the 32-bit wide PCI bus. Its PCI configuration registers allow it to function as the PCI bus target and initiator. The VIP chip:

- Functions as a PCI slave to all processor I/O read and write operations that target the VIP registers, the CY7C964 chip registers, the scatter/gather RAM, or VME memory space
- Responds to PCI interrupt acknowledge cycles when set up as the PCI interrupt responder
- Functions as a PCI master in response to the VIC64 chip requesting data from or sending data to PCI memory
- Performs address translation between the PCI bus and the VMEbus for transfers to and from the VMEbus

1.10.2 VIC64 and CY7C964 Chips

The VIC64 and CY7C964 chips control the VMEbus. The VIC64 chip functions as a VMEbus slave in response to VME addresses that match those set up by the address base and address base mask registers. This chip functions as VMEbus master:

- In response to the processor reading from and writing to VME memory (programmed I/O)
- To execute DMA transactions (master block transfers) set up by the processor in the VIP/VIC64 interface

For more information on the VIC64 and CY7C964 chips, see the Cypress Semiconductor *VIC068 User's Guide*, VIC64 design notes, and *CY7C964 User's Guide*.

1.10.3 Address Mapping and the Scatter-Gather Map

The VIP chip translates addresses by using a mapping table in scatter-gather RAM called the scatter-gather map. The scatter-gather map translates addresses for outbound and inbound VMEbus transactions.

For outbound transactions, the VIP chip maps a 512 MB region of PCI memory space to the VMEbus. The outbound scatter-gather map translates a maximum of 2K naturally aligned 256 KB pages within that 512 MB region to 256 KB of naturally aligned pages on the VMEbus (A32, A24, or A16). A PCI address is used as an index into the scatter-gather map to give the corresponding VME address.

For inbound transactions, the VIP chip maps naturally aligned 8 KB regions of VMEbus A32 and A24 address spaces to naturally aligned 8 KB regions of PCI address space (memory or I/O). The inbound scatter-gather map consists of two parts. One part translates up to 2K pages (8 KB) of VMEbus A24 address space to 8 KB pages of PCI address space. The other part maps up to 16K pages (8 KB) of VMEbus A32 address space to 8 KB pages of PCI address space. An incoming VME address is used as the index to select the PCI address.

The scatter-gather map may be accessed from the PCI bus (written to or read from) under VIP control. Scatter-gather entries also contain information to control inbound accesses and byte swapping.

The VIP chip contains a single entry scatter-gather cache and a set of registers. The cache stores the last accessed outbound scatter-gather entry and its corresponding scatter-gather address index. The registers provide mapping for inbound and outbound transactions (one mapping in each direction).

For more information about VME interface address mapping, see Chapter 2.

System Address Mapping

The CIA chip of the 21172 core logic chip set manages system address mapping for Alpha VME 5/352 and 5/480 SBCs. The chip maps 40-bit physical addresses of the 21164 microprocessor to memory and I/O space addresses.

This chapter discusses DIGITAL Alpha VME 5/352 and 5/480 SBC support for the 21172 core logic chipset. The chapter provides an address space overview (Section 2.1) and describes:

- PCI dense memory space, Section 2.2
- PCI sparse memory space, Section 2.3
- PCI sparse I/O space, Section 2.4
- PCI configuration space, Section 2.5
- Byte/word PCI space, Section 2.6

For details about 21172 core logic chipset address mapping, see the *Digital Semiconductor 21172 Core Logic Chipset Technical Reference Manual*.

2.1 Address Space Overview

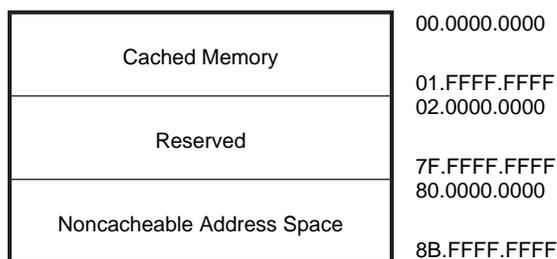

Sections 2.1.1 through 2.1.3 provide an overview of Alpha VME 5/352 and 5/480 SBC address space by discussing:

- Cached and noncacheable regions, Section 2.1.1
- Supported address spaces, Section 2.1.2
- 21164 address space mappings, Section 2.1.3

2.1.1 Cached and Noncacheable Regions

The address space of the 21164 microprocessor is divided into two regions: cached memory and noncacheable address space. Figure 2–1 shows these regions as they are mapped with the 21172 core logic chipset support.

Figure 2–1 21164 Microprocessor Address Space

LJ04259A.AI

The region of the address space that is accessible to the microprocessor at any given time is determined by physical address bit **addr<39>**. When this bit is clear, the microprocessor has access to cacheable memory (partly reserved). When the bit is set, the microprocessor has access to noncacheable address space. The system uses noncacheable address space for:

- PCI address space mapped to memory
- PCI I/O space
- PCI configuration information
- Special/interrupt acknowledge cycles
- CIA control/status registers (CSRs)
- Flash ROM and support logic registers

2.1.2 Supported Address Spaces

The CIA chip supports the following address spaces:

- The first 8 GB of cached memory space
- Noncacheable memory space mapped for I/O devices

The remainder of the cached memory space is reserved. The block size for the cached memory space is 64-bytes. The CIA chip sends READ and FLUSH commands to the microprocessor's caches for direct-memory access (DMA) traffic to the 8 GB of cached memory address space.

Within the noncacheable memory space, the Alpha VME 5/352 and 5/480 SBC firmware implements the following address spaces:

Address Space	Firmware Implementation
PCI dense memory space	2 GB
PCI sparse memory space	128 MB
PCI sparse I/O space	16 MB
PCI configuration space	4 GB

Figure 2–2 shows the 21164 address space configuration as supported by the Alpha VME 5/352 and 5/480 SBCs.

Figure 2–2 21164 Address Space Configuration

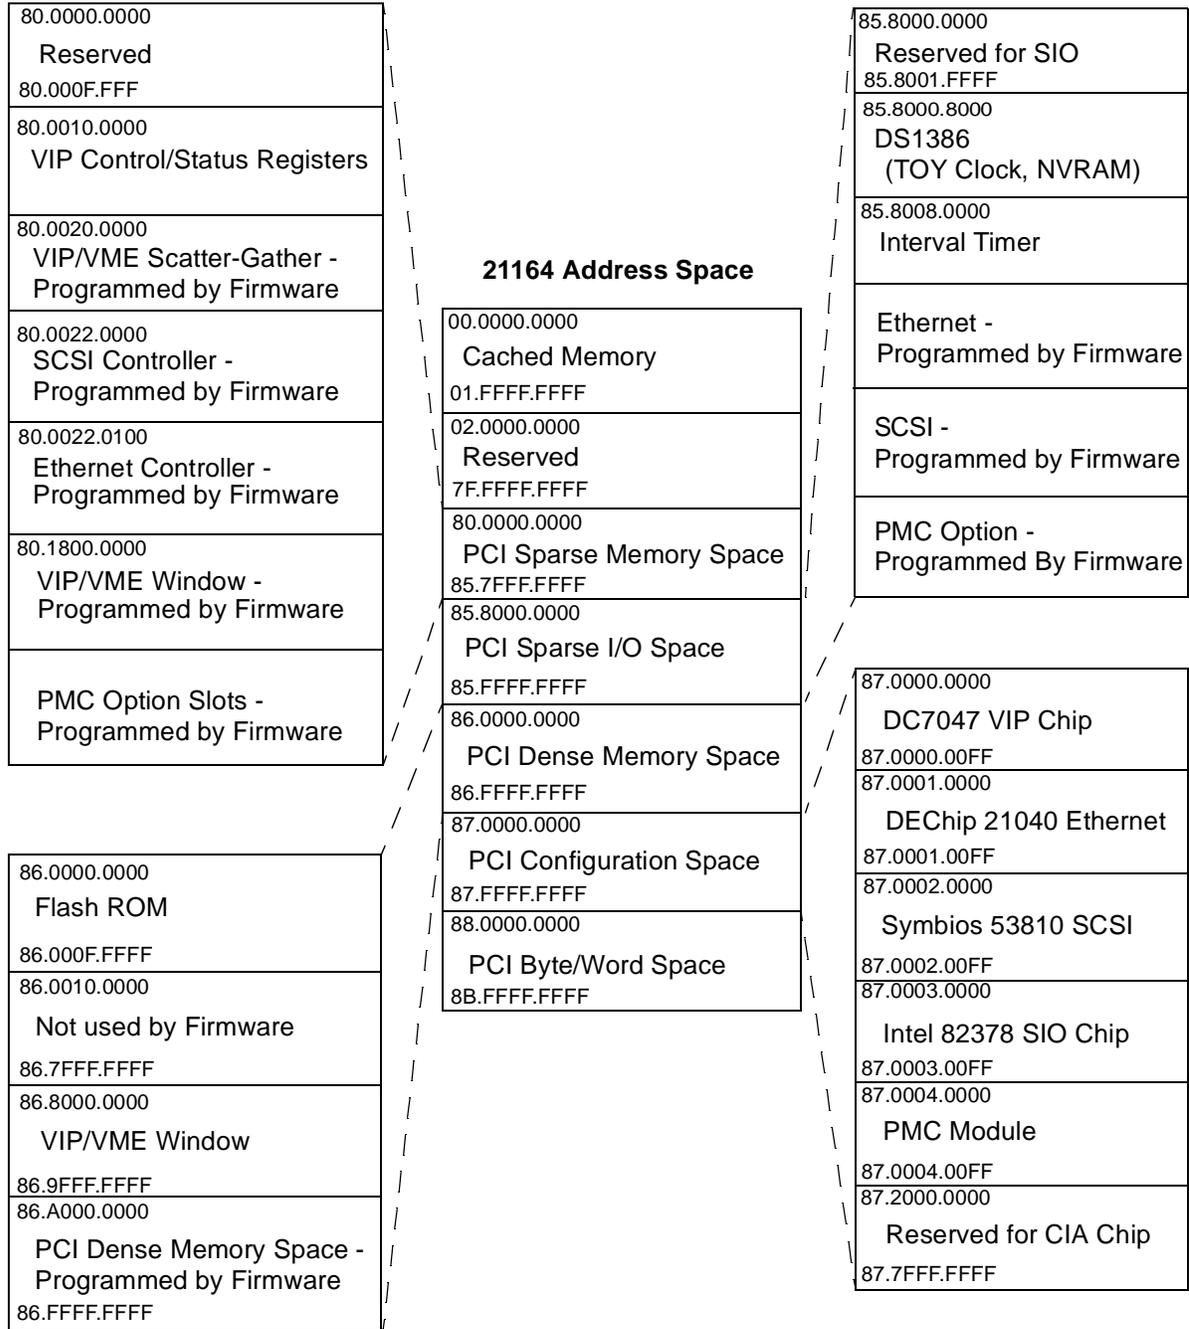

Table 2–1 shows how the Alpha VME 5/352 and 5/480 SBC firmware implements the 21164 physical address space mappings.

Table 2–1 21164 Physical Address Space Mappings

Physical Address Range	Description	Firmware Implementation
00.0000.0000 – 01.FFFF.FFFF	Cached memory	8 GB
02.0000.0000 – 7F.FFFF.FFFF	Reserved	
80.0000.0000 – 85.7FFF.FFFF	PCI sparse memory space	128 MB
80.0000.0000 – 80.000F.FFFF	PCI sparse memory space – Reserved	
80.0010.0000	PCI sparse memory space – VIP control/status registers	512 Bytes
80.0020.0000	PCI sparse memory space – VIP/VME Scatter-Gather – programmed by firmware	128 KB
80.0022.0000	PCI sparse memory space – SCSI controller – programmed by firmware	
80.0022.0100	PCI sparse memory space – Ethernet controller – programmed by firmware	
80.1800.0000	PCI sparse memory space – VIP/VME Window – programmed by firmware	64 MB
	PCI sparse memory space – PMC Option Slots – programmed by firmware	
85.8000.0000 – 85.FFFF.FFFF	PCI sparse I/O space	16 MB
85.8000.0000 – 85.8001.FFFF	PCI sparse I/O space – Reserved for SIO	
85.8000.8000	PCI sparse I/O space – DS1386 (TOY Clock, NVRAM)	
85.8008.0000	PCI sparse I/O space – Interval timer	
85.8001.0000 – 85.8100.0000	PCI sparse I/O space – programmed by firmware	16 MB - 64 KB
86.0000.0000 – 86.FFFF.FFFF	PCI dense memory space	2 GB
86.0000.0000 – 86.000F.FFFF	PCI dense memory space – Flash ROM	1 MB
86.0010.0000 – 86.7FFF.FFFF	PCI dense memory space – Not used by firmware	
86.8000.0000 – 86.9FFF.FFFF	PCI dense memory space – VIP/VME Window	512 MB
86.A000.0000 – 86.FFFF.FFFF	PCI dense memory space – programmed by firmware	1.5 GB
87.0000.0000 – 87.FFFF.FFFF	PCI configuration space	4 GB
87.0000.0000 – 87.0000.00FF	PCI configuration space – DC7407 VIP chip	
87.0001.0000 – 87.0001.00FF	PCI configuration space – DECchip 21040 Ethernet	
87.0002.0000 – 87.0002.00FF	PCI configuration space – Symbios 53810 SCSI	
87.0003.0000 – 87.0003.00FF	PCI configuration space – Intel 82378 SIO chip	

Table 2–1 21164 Physical Address Space Mappings (Continued)

Physical Address Range	Description	Firmware Implementation
87.2000.0000 – 87.7FFF.FFFF	PCI configuration space – Reserved for CIA chip	
88.0000.0000 – 8B.FFFF.FFFF	Byte/word PCI space ¹	
88.0000.0000 – 88.FFFF.FFFF	Byte/word PCI memory space ¹	
89.0000.0000 – 89.FFFF.FFFF	Byte/word PCI I/O space ¹	
8A.0000.0000 – 8A.FFFF.FFFF	Byte/word PCI configuration space – type 0 ¹	
8B.0000.0000 – 8B.FFFF.FFFF	Byte/word PCI configuration space – type 1 ¹	

¹Not used by the firmware, but available for use by operating systems.

Note

The results of gaining access to address space outside the physical address ranges shown in Table 2–1 are undefined.

2.1.3 21164 Address Space

The 21164 microprocessor address space consists of 17 address regions that range in size from 0.25 GB to 16 GB. Sections 2.2 through 2.6 describe the following address regions:

- PCI dense memory space, Section 2.2
- PCI sparse memory space, Section 2.3
- PCI sparse I/O space, Section 2.4
- PCI configuration space, Section 2.5
- PCI byte/word space, Section 2.6

2.2 PCI Dense Memory Space

PCI dense memory space is typically used for PCI data buffers, such as video frame buffers or nonvolatile RAM (NVRAM). The Alpha VME 5/352 and 5/480 SBC firmware implements PCI dense memory space in the address range 86.0000.0000 to 86.7FFF.FFFF.

Sections 2.2.1 to 2.2.6 discuss the following:

- Dense memory space characteristics, Section 2.2.1
- Advantages of dense memory space over sparse memory space, Section 2.2.2
- Dense memory space address generation, Section 2.2.3
- Flash ROM address mapping, Section 2.2.4
- VME address mapping in dense memory space, Section 2.2.5
- How to gain access to dense memory space, Section 2.2.6

2.2.1 Characteristics

Dense memory space is provided for the 21164 microprocessor to gain access to PCI memory space, but not PCI I/O space. Dense memory space has the following characteristics:

- A one-to-one mapping exists between 21164 microprocessor addresses and PCI addresses. A 21164 microprocessor longword address maps to a longword on the PCI with no shifting of the address field.
- The concept of dense memory space (and sparse space) is applicable only to addresses generated by the 21164 microprocessor. The PCI bus does not generate dense memory space (or sparse space).
- Access to a byte or word is *not* possible in dense memory space. The minimum access granularity is a longword on write transactions and a quadword on read transactions. The maximum transfer length is 32 bytes (performed as a burst of 8 longwords on the PCI bus). Any combination of longwords may be valid on write transactions. Valid longwords surrounding invalid longwords (called a “hole”) must be handled correctly by all PCI devices. The CIA chip allows such “holes” to be issued.
- Read transactions consist of a burst of two or more longwords on the PCI bus because the minimum granularity is a quadword. The microprocessor can request a longword but the CIA chip always fetches a quadword, thus prefetching a second longword. Therefore, you cannot use dense memory space for devices that generate side effects when performing a read transaction. Although a longword may be prefetched, the prefetch buffer is not treated as a cache and thus coherency is not an issue. A quadword read transaction is not atomic on the PCI bus. That is, the target device is at liberty to force a retry after the first longword of data is sent, and then allow another device to take control of the PCI bus. The CIA chip does not drive the PCI lock signal and thus the PCI bus cannot ensure atomicity. This is true of all current Alpha systems using the PCI bus.
- The 21164 microprocessor merges noncached read transactions up to a 32-byte maximum. The largest dense memory space read transaction from the PCI bus is 32 bytes.
- Write transactions to dense memory space are buffered in the 21164 microprocessor. The CIA chip supports a burst length of 8 on the PCI bus, corresponding to 32 bytes of data. In addition, the CIA chip provides four 32-byte write buffers to maximize I/O write performance. These four buffers are strictly ordered.

2.2.2 Advantages Over Sparse Space

Dense memory space does not allow byte or word access but has the following advantages over sparse space:

- Contiguous memory locations

Some software requires PCI transactions to be at adjacent 21164 addresses, instead of being widely separated as in sparse space.

- Higher bus bandwidth
PCI bus burst transfers are not usable in sparse space except for a 2-long-word burst for quadword write transactions. Dense memory space is defined to allow both burst read and write transactions.
- Efficient read/write buffering
In sparse space, separate transactions use separate read or write buffer entries. Dense memory space allows separate transactions to be collapsed in read and write buffers.
- Few memory barriers
In general, transactions that gain access to sparse space are separated by memory barriers to avoid read/write buffer collapsing. Transactions that gain access to dense memory space only require barriers when the software requires explicit ordering.

2.2.3 Address Generation

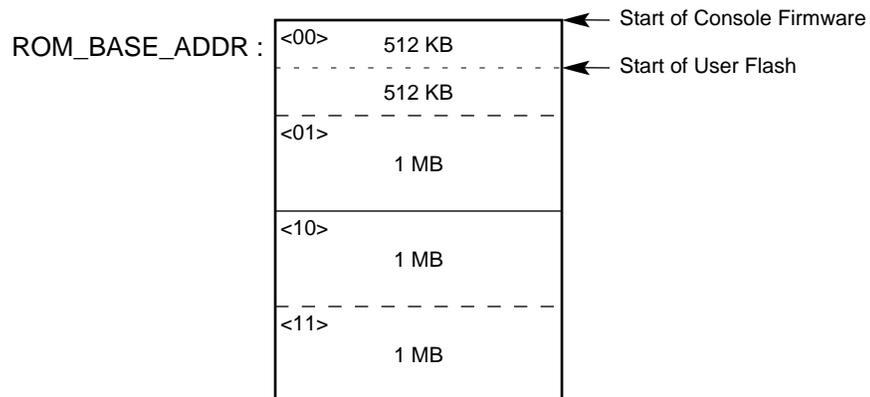

For information on address generation in dense memory space, see the *Digital Semiconductor 21172 Core Logic Chipset Technical Reference Manual*.

2.2.4 Flash ROM Address Mapping

The flash ROM maps to dense memory space. Figure 2–3 shows the system has a total of 4 MB of flash ROM, which is divided into four 1 MB segments. The 21164 and PCI dense memory addresses for this memory space are as follows:

Address Type	Physical Address Range
21164	86.0000.0000 – 86.0007.FFFF
PCI dense memory	ROM_BASE_ADDR = 0000.0000

Figure 2–3 Flash ROM Layout/Addressing

ML013291

Only byte accesses to the ROM are supported. As Figure 2–3 shows, the first 512 KB of flash ROM are reserved for console firmware use. The remaining space in the flash ROM is reserved for onboard user code.

You can control and gain access to the flash ROM by using the module control register 1 (MOD_CNTRL_REG_1). For a description of this register, see Section 5.4.3.7.

2.2.5 VME Address Mapping

Alpha VME 5/352 and 5/480 SBCs support VME address spaces A16, A24, and A32, using two address windows to map from PCI memory space to VME address space. One of the address windows, VME_WINDOW_1, maps from PCI dense memory space. This 512 MB address window is divided into 2048 X 256 KB pages. Each page is mapped to VME address space by its own scatter-gather entry. The entries of the first 256 pages are also used to map pages of the second address window, VME_WINDOW_2, which allows access to PCI sparse memory space.

For information on how VME_WINDOW_2 maps to PCI sparse memory space, see Section 2.3.3. For more detail on VME address mapping, see Section 3.2.

2.2.6 Gaining Access to PCI Dense Memory Space

To gain access to PCI dense memory space, specify a dense space address with the **examine** console command as follows:

```
>>>examine pmem:address
```

For example:

```
>>>examine pmem:860000000
```

2.3 PCI Sparse Memory Space

PCI sparse memory space maps a large piece of 21164 memory address space to a small PCI address space. For example, a 32-byte memory address might map to a 1-byte PCI address. The Alpha VME 5/352 and 5/480 SBC firmware implements PCI sparse memory space in the address range 80.0000.0000 to 80.07DF.FFFF.

A problem arises because the Alpha instruction set can express only ALIGNED longword and quadword data references. The PCI bus requires the ability to express byte, word, tribyte, longword, and quadword references. The CIA must also be able to emulate PCI transactions for PCI devices designed for systems that are capable of generating the UNALIGNED references.

The CIA chip accomplishes UNALIGNED PCI references by encoding the size of the data transfer (byte, word, and so on) and the byte-enable information in address bits **addr<6:3>** of the 21164 address. The PCI longword address bits **ad<26:3>** are generated by using the remaining address bits **addr<31:7>**.

For information on quadword address encoding, see the *Digital Semiconductor 21172 Core Logic Chipset Technical Reference Manual*.

Sections 2.3.1 to 2.3.4 discuss the following:

- Low-order address bits in sparse memory space, Section 2.3.1
- High-order address bits in sparse memory space, Section 2.3.2
- VME address mapping in sparse memory space, Section 2.3.3

- How to gain access to sparse memory space, Section 2.3.4

2.3.1 Low-Order Address Bits

Low-order PCI sparse memory space address bits **addr<7:3>** generate the length of the PCI bus transaction in bytes and are used for byte enables and **ad<2:0>**. Address bits **addr<30:8>** correspond to the quadword PCI address and are sent on the PCI bus as **ad<25:3>**.

For more information on the low-order address bits for PCI sparse memory space, see the *Digital Semiconductor 21172 Core Logic Chipset Technical Reference Manual*.

2.3.2 High-Order Address Bits

High-order PCI sparse memory space address bits **ad<31:26>** are obtained from the hardware address extension register (HAE_MEM) or the 21164 address, depending on sparse space regions.

For more information on the high-order address bits for PCI sparse memory space, see the *Digital Semiconductor 21172 Core Logic Chipset Technical Reference Manual*.

2.3.3 VME Address Mapping

Alpha VME 5/352 and 5/480 SBCs support VME address spaces A16, A24, and A32, using two address windows to map from PCI memory space to VME address space. One of the windows, VME_WINDOW_2, allows mapping to PCI sparse memory space. This 64 MB address window is divided into 256 X 256 KB pages. The pages are mapped by the same scatter-gather entries that map the first 256 pages in VME_WINDOW_1 (see Section 2.2.5).

For more detail about VME address mapping, see Section 3.2.

2.3.4 Gaining Access to PCI Sparse Memory Space

To gain access to PCI sparse memory space, specify a sparse space address with the **examine** console command as follows:

```
>>>examine pmem:address
```

For example:

```
>>>examine pmem:800000000
```

For rules on gaining access to PCI sparse memory space, see the *Digital Semiconductor 21172 Core Logic Chipset Technical Reference Manual*.

2.4 PCI Sparse I/O Space

PCI sparse I/O space has characteristics similar to the PCI sparse memory space. A read or write transaction to this space causes a PCI I/O read or write transaction. The Alpha VME 5/352 and 5/480 SBC firmware implements PCI sparse I/O space in the address range 85.8000.0000 to 85.80FF.FFFF.

Note

All devices on the Nbus reside in PCI sparse I/O space.

Sections 2.4.1 to 2.4.4 discuss the following:

- High-order address bits in sparse I/O space, Section 2.4.1
- Sparse I/O space address decoding, Section 2.4.2
- Generation of sparse I/O space addresses, Section 2.4.3
- How to gain access to sparse I/O space, Section 2.4.4

2.4.1 High-Order Address Bits

High-order PCI sparse I/O space address bits **addr<34:30>** are equal to 10110₂. These bits address the lower 32 MB of PCI sparse I/O space. Bits **ad<31:25>** are set to zero by the hardware.

For more information on the high-order address bits for PCI sparse I/O space, see the *Digital Semiconductor 21172 Core Logic Chipset Technical Reference Manual*.

2.4.2 Address Decoding

PCI sparse I/O space regions are negatively decoded and are not affected by another PCI device that is programmed to positively decode PCI addresses.

2.4.3 Address Generation

For information on PCI sparse I/O space address generation, see the *Digital Semiconductor 21172 Core Logic Chipset Technical Reference Manual*.

2.4.4 Gaining Access to PCI Sparse I/O Space

To gain access to PCI sparse I/O space, specify a PCI I/O space address with the **examine** console command as follows:

```
>>>examine pciio:address
```

For example:

```
>>>examine pciio:8580000000
```

2.5 PCI Configuration Space

The PCI configuration register set occupies PCI configuration space. The Alpha VME 5/352 and 5/480 SBC firmware implements PCI configuration space in the physical address range 87.0000.0000 to 87.1FFF.FFFF.

The base address of each PCI device, except the Nbus interface (SIO), is configured by the system firmware. The firmware initializes each base address by writing the configuration registers that are in the PCI configuration space.

Note

Software designers should clear CIA_CTRL[FILL_ERR_EN] when probing for PCI devices using configuration space read transactions. This prevents the CIA chip from generating an ECC error if no device responds to the configuration cycle and UNPREDICTABLE data is read from the PCI bus.

Sections 2.5.1 to 2.5.3 discuss the following:

- Device type selection, Section 2.5.1
- Configuration space address generation, Section 2.5.2
- CIA chip registers, Section 2.5.3
- How to gain access to configuration space, Section 2.5.4

2.5.1 Device Type Selection

A CPU read or write transaction to PCI configuration address space causes a configuration read or write cycle on the PCI bus. Each transaction is associated with one of two types of target devices defined as follows:

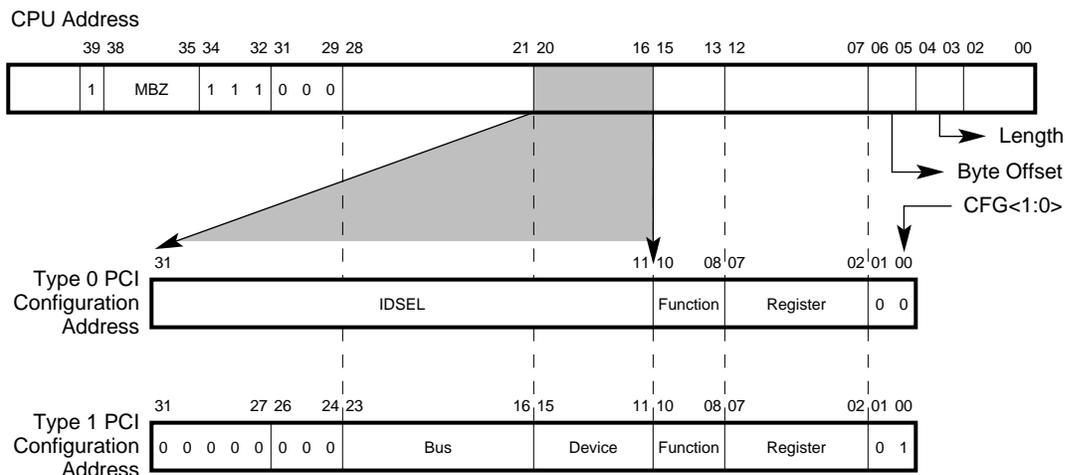

Type	Target Devices
0	Devices on the primary 64-bit 21164 system PCI bus.
1	Devices on the secondary 32-bit 21164 system PCI bus (that is, behind a PCI-to-PCI bridge).

As shown in Figure 2–4, the value of the configuration register determines the target device type. To select Type 0 target devices, set bits **CFG<1:0>** equal to 00₂. To select Type 1 target devices, set the bits to 01₂.

Note

Bits **CFG<1:0>** set to 10₂ and 11₂ are reserved by the PCI specification.

Figure 2–4 PCI Configuration Space Definition

LJ04270A.AI4

Notes

You must program the configuration register before running a configuration cycle. Sparse address decoding is used.

The CIA chip uses bits **CFG<1:0>** instead of unused address bits **addr<38:35>** to be compatible with the Digital Semiconductor 21071 core logic chipset, used with Alpha 21064 series microprocessors.

2.5.2 Address Generation

For information on PCI configuration space address generation, see the *Digital Semiconductor 21172 Core Logic Chipset Technical Reference Manual*.

2.5.3 CIA Chip Hardware Registers

For information on the CIA hardware registers, see the *Digital Semiconductor 21172 Core Logic Chipset Technical Reference Manual*.

Note

CIA hardware registers are programmed by the firmware and operating system. If you modify these registers, the results may be undefined.

2.5.4 Gaining Access to PCI Configuration Space

To gain access to PCI configuration space, enter the examine console command as follows:

```
>>>e pcicfg:hhbssffoo
```

For *hhbbssffoo* specify:

Parameter	Description
<i>hh</i>	The PCI hose (you can omit this because it will always be 00 for Alpha VME 5/352 and 5/480 SBCs)
<i>bb</i>	The PCI bus number with the primary bus being 00
<i>ss</i>	The slot location of the device
<i>ff</i>	The function for multifunction devices
<i>oo</i>	The offset into PCI configuration space as defined in the PCI specification

To get the vendor ID of the Symbolics 53C810, enter the following command:

```
>>>sho config

                Digital Equipment Corporation
                AlphaVME 5/352

SRM Console V1.1-0   VMS PALcode V1.20-9, OSF PALcode V1.22-8

                MEMORY:      64 Meg of system memory
System Controller:  VIC64 Enabled

Hose 0, PCI
slot 0 DECchip 7407
slot 1 DECchip 21040-AA   ewa0.0.0.1.0   00-00-F8-23-6C-53
slot 2 NCR 53C810       pka0.7.0.2.0   SCSI Bus ID 7
slot 3 Intel 82378

>>>e pcicfg:0000020000 -w
pcicfg:      20000   1000
>>>
```

2.6 Byte/Word PCI Space

PCI byte/word space supports byte/word instructions that allow software to gain access to I/O space with byte granularity without using sparse space. The Alpha VME 5/352 and 5/480 SBC firmware does not use byte/word PCI space. However, byte/word PCI space is available for use by operating systems. For more information on this address space, see the *Digital Semiconductor 21172 Core Logic Chipset Technical Reference Manual*.

VME Interface

The VME interface handles the VMEbus and its interactions with the PCI bus. This chapter describes the functions of the VME interface controlled by the operating system. The chapter provides a brief overview of the primary services the VME interface provides (Section 3.1) and explains:

- VME address mapping, Section 3.2
- VME interface initialization, Section 3.3
- How a device requests ownership of the VMEbus, Section 3.4
- How a VME master transfers data, Section 3.5
- How VME slaves handle interprocessor communication, Section 3.5.5
- How an Alpha VME 5/352 or 5/480 SBC can function as VMEbus system controller, Section 3.6
- Support for byte swapping, Section 3.7

See your operating system documentation for specific instructions on configuring the VME interface.

3.1 Services Supported by the VME Interface

You can program or configure the VME interface for a given Alpha VME 5/352 or 5/480 SBC such that the SBC serves as the VMEbus master, a VMEbus slave, or the VMEbus system controller. Table 3–1 lists the possible roles of the VME interface and the services the interface offers for each role:

Table 3–1 Services Offered by the VME Interface

As	The VME Interface
VMEbus master	Controls PCI-to-VME (outbound) transactions.
VMEbus slave	Handles VME-to-PCI (inbound) transactions and interprocessor communication.
VMEbus system controller	Handles arbitration of bus ownership, drives the sysclk signal to the VMEbus, serves as arbitration watchdog, acts as VMEbus interrupter and VMEbus interrupt servicing agent

3.2 VMEbus Address Mapping

Section 3.2.1 provides an address mapping overview. Sections 3.2.2 and 3.2.3 discuss outbound scatter-gather mapping and inbound scatter-gather mapping, respectively.

3.2.1 Address Mapping Overview

Alpha VME 5/352 and 5/480 SBCs support VME address spaces A16, A24, and A32, using two address windows. The address windows map PCI memory address space to VME address space as explained in Table 3–2.

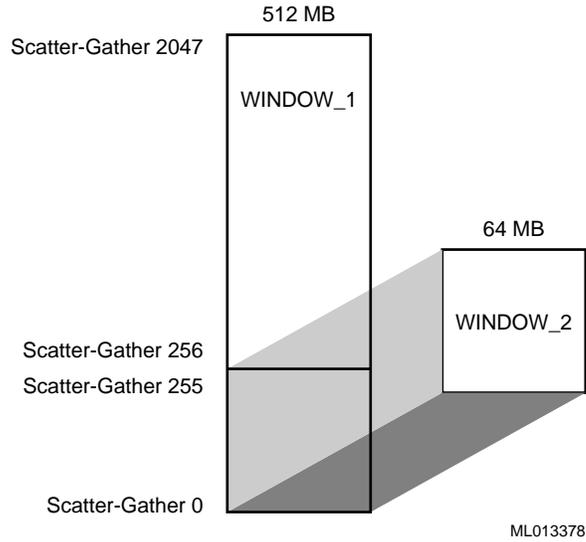

Table 3–2 VME Address Windows

VME Address Window	Address Mapping
VME_WINDOW_1	A 512 MB address window positioned in PCI dense memory address space. This window is divided into 2048 x 256 KB pages. Each page is mapped to VME address space by a scatter-gather map entry. The scatter-gather map entries of the first 256 pages are also used to map the VME_WINDOW_2 pages.
VME_WINDOW_2	A 64 MB address window positioned in PCI memory space. This window is divided into 256 x 256 KB pages. These pages are mapped by the same scatter-gather map entries that map the first 256 pages in VME_WINDOW_1. The VME_WINDOW_2 address space can map to PCI sparse memory space.

Each of the first 256 scatter-gather map entries maps two pages to the same VME address: a unique page within VME_WINDOW_1 and an overlapped page within VME_WINDOW_2. For example, entry 5 of the outbound scatter-gather RAM maps page 5 of VME_WINDOW_1 and page 5 of VME_WINDOW_2 to exactly the same VME address.

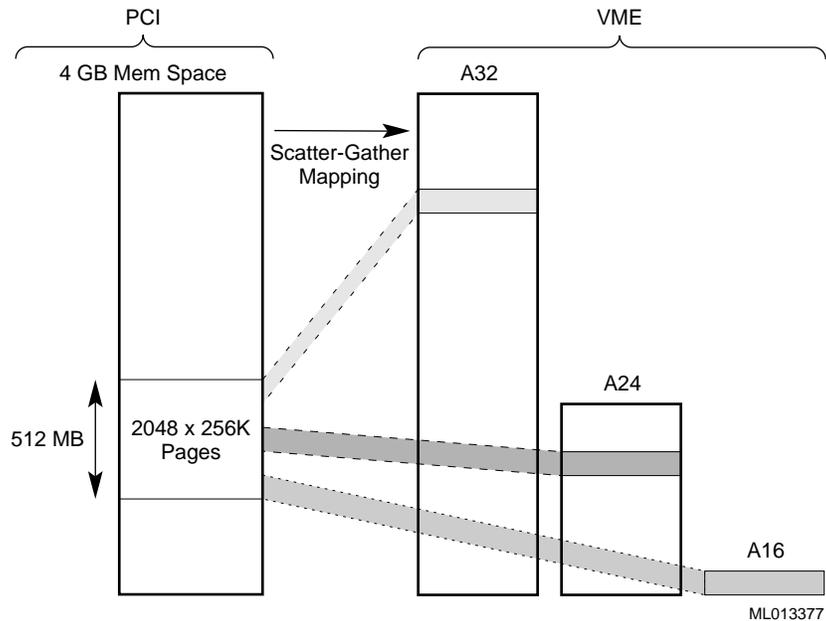

Figure 3–1 shows a mapping of VME_WINDOW_1 and VME_WINDOW_2.

Figure 3–1 Mapping of VME_WINDOW_1 and VME_WINDOW_2

Each page of PCI memory space can be mapped to any one of the three VMEbus address spaces: A32, A24, or A16. As shown in Figure 3–2, numerous pages can be mapped to the same VMEbus address to allow access to the same location with different modes. The address modifier code (see Section 3.2.2.2) is fully programmable for each page.

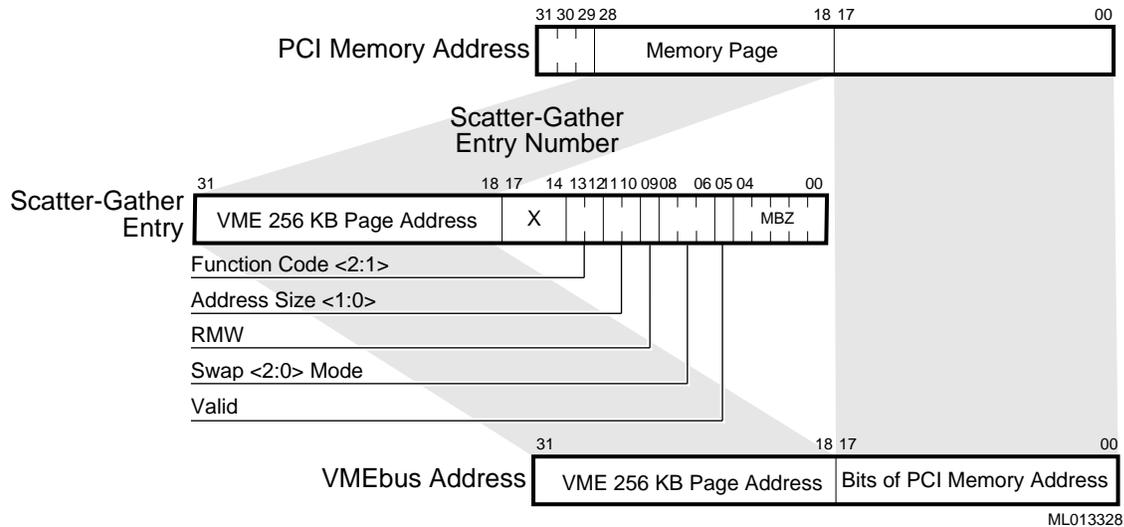

Figure 3–2 Mapping Pages From PCI Address Space to VME Address Space

3.2.2 Outbound Scatter-Gather Mapping

Outbound scatter-gather map entries control and map VMEbus master transactions. The source of the transactions is the VME SBC serving as master and the destination is the VMEbus. Figure 3–3 shows how a scatter-gather map entry is used for PCI-to-VMEbus outbound address translation. Tables 3–3 and 3–4 describe the address fields of an outbound scatter-gather map entry.

Figure 3–3 PCI-to-VMEbus Outbound Address Translation

ML013328

Table 3–3 PCI Address in an Outbound Scatter-Gather Map Entry

Field	Name	Description
<4:0>	MBZ	
<5>	Valid	
<8:6>	Swap	
<9>	RMW	When set, enables atomic VMEbus read-modify-write (RMW) cycles. For more information, see Section 3.2.2.1.
<11:10>	Address Size	Identifies whether the address size (ASIZ) is A32, A24, A16, or is user defined. For more information, see Section 3.2.2.2
<13:12>	Function Code	Indicates whether the address points to user data, a user program, supervisory data, a supervisory program, a user page, or a supervisory page. For more information, see Section 3.2.2.2.
<17:14>	Not Used	
<31:18>	VME Page	Page frame number.

Table 3–4 VME Address in an Outbound Scatter-Gather Map Entry

Field	Description
<31:18>	VME page, that is, bits <28:18> of the PCI address.

The processing of an outbound scatter-gather map entry is as follows:

1. The correct scatter-gather map entry is identified.

The PCI address is compared to the contents of the base registers for VME_WINDOW_1 and VME_WINDOW_2. PCI address bits <31:29> are compared to the contents of register VME_WINDOW_1_BASE and PCI address bits <31:26> are compared to the contents of register VME_WINDOW_2_BASE.

If the comparison results in a match, a scatter-gather lookup occurs. The scatter-gather entry is identified using either PCI address bits <28:18> or PCI address bits <25:18>. If the PCI memory cycle addresses VME_WINDOW_1, the scatter-gather entry is identified by PCI address bits <28:18>. If the PCI memory cycle addresses VME_WINDOW_2, the scatter-gather entry is identified by PCI address bits <25:18>.

Bits <31:18> of the scatter-gather entry provide the page address (VME address bits <31:18>) of the corresponding aligned 256 KB VMEbus page address. PCI address bits <17:2>, together with the PCI byte enables, specify the byte address within that page.

2. The scatter-gather map entry's valid bit, bit <5>, is checked.

If the valid bit is set, the VME interface forms the VMEbus address from the scatter-gather map entry. If the bit is not set, the scatter-gather map entry is invalid and no VMEbus transaction can occur. Instead, the outbound Error bit in the VME interface processor bus error/status register (VIP_BESR) is set. If the corresponding bit is also set in the VME interface processor interrupt control register (VIP_ICR), this event causes a DC7407 interrupt assertion.

Sections 3.2.2.2 and 3.2.2.1 describe RMW and address modifier fields of the scatter-gather map entries.

3.2.2.1 Read-Modify-Write Bit

When a scatter-gather entry's read-modify-write (RMW) bit is set, any master access to that page causes the VME interface to perform the next two accesses as a single sequence of VMEbus cycles. The two accesses are:

- The one whose scatter-gather entry has the RMW bit set
- The next PCI cycle that addresses the VMEbus

The two accesses are handled as an indivisible sequence on the VMEbus by acquiring VMEbus ownership for the current access and holding it until another master operation is done by the processor. This is designed for doing atomic VMEbus RMW cycles.

The VIC interface configuration register must be programmed with **VIC_ICR<7:5> = 001**. A value of **VIC_ICR<7:5> = 000** disables the RMW mode regardless of the setting in the scatter-gather map, while any other **VIC_ICR<7:5>** value gives UNPREDICTABLE results.

To use the RMW mechanism, software must be able to guarantee sequential execution of the two PCI cycles to the VMEbus on the PCI bus.

An alternate way of defining a divisible sequence is to use the VIC64 chip's "bus capture and hold" mechanism, described in Section 3.6.1.

3.2.2.2 Address Modifiers

A scatter-gather map entry has two fields that provide an address modifier that is used in the master VMEbus transfer. The address modifier consists of the address size (ASIZ) and a function code (FC) that map directly to the VIC chip's inputs for ASIZ and FC. Table 3-5 shows the use of the ASIZ and FC fields.

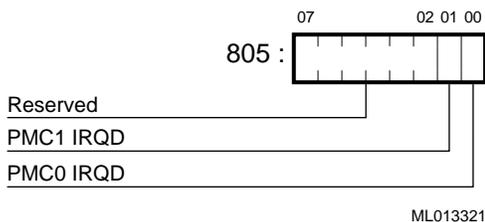

Table 3-5 Formation of Address Modifier Codes from Scatter-Gather Entry

ASIZ1/0	FC2/1	Block Mode	Operation	AM<5:0>
01 (A32)	00	No	User Data	0x09
	01	No	User Program	0x0A
	10	No	Supervisory Data	0x0D
	11	No	Supervisory Program	0x0E
	0x	Yes	User Page	0x0B (D32) 0x08 (D64)
	1x	Yes	Supervisory Page	0x0F (D32) 0x0C (D64)
11 (A24)	00	No	User Data	0x39
	01	No	User Program	0x3A
	10	No	Supervisory Data	0x3D
	11	No	Supervisory Program	0x3E
	0x	Yes	User Page	0x3B (D32) 0x38 (D64)
	1x	Yes	Supervisory Page	0x3F (D32) 0x3C (D64)
10 (A16)	0x	No	User Access	0x29
	1x	No	Supervisory Access	0x2D
00	User	Defined	AM Codes	VIC_AMSR

3.2.3 Inbound Scatter-Gather Mapping

The VME interface responds to A32, A24, and A16 access cycles as shown in Figure 3–4. A32 and A24 cycles are used to access the memory of an Alpha VME 5/352 or 5/480 SBC. Incoming A32 and A24 transactions are mapped to 8 KB pages by the VME interface’s inbound scatter-gather maps. A16 cycles provide access to a small number of byte-wide interprocessor communication registers.

Figure 3–4 Mapping Pages from VME Address Space to PCI Address Space

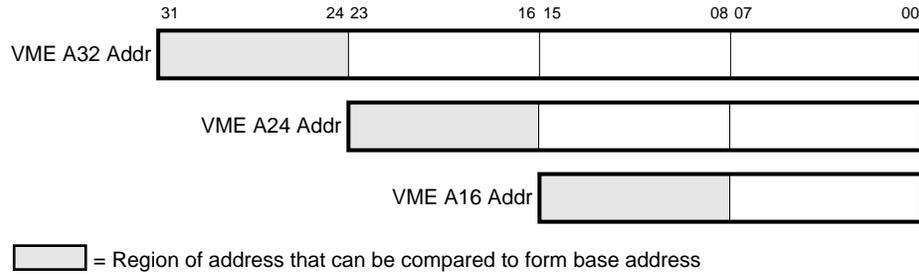

Incoming slave accesses are mapped and controlled by two incoming scatter-gather maps:

For Access Type	An Alpha VME 5/352 or 5/480 SBC Occupies
A32	Up to 128 MB of memory mapped by 16384 scatter-gather entries. Each entry maps an 8 KB page.
A24	Up to 16 MB of memory mapped by 2048 scatter-gather entries. Each entry maps an 8 KB page.

3.2.3.1 Decoding Addresses

The VME-to-PCI address decoding is implemented using CY7C964 bus interfaces within the VME interface. As Figure 3–5 shows, three CY7C964 bus interfaces are accessed together in the VMEbus i/f address base and mask registers (VIF_ABR and VIF_MASK). The registers must be accessed as longwords even though the individual bytes represent address match data for separate VME address spaces.

Figure 3–5 VME Address Decoding

ML013341

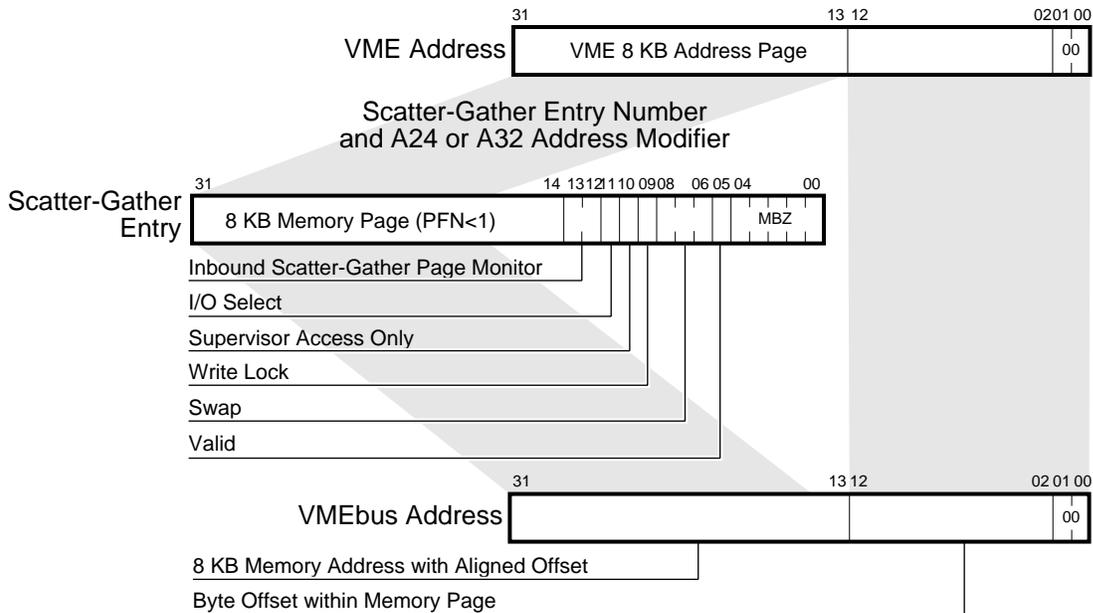

VIF_ABR defines the base address of the system in each VMEbus address space.

See the *CY7C964* specification for more detail on the byte comparisons. For a description of the VIF_ABR register, see the *CY7C9640 Specification*.

3.2.3.2 Scatter-Gather Map Entry Format

Figure 3–6 shows a scatter-gather map entry being used for VMEbus-to-PCI inbound address translation. The address modifier bits determine the scatter-gather map that is to be searched. Tables 3–6 and 3–7 describe the VMEbus and PCI address fields of a scatter-gather map entry.

Figure 3–6 VMEbus-to-PCI Inbound Address Translation for A32

ML013342

Table 3–6 VME Address in an Inbound Scatter-Gather Map Entry

Field	Name	Description
<4:0>	MBZ	
<5>	Valid	
<8:6>	Swap	
<9>	Write Lock	Limits slave accesses to read-only, that is, a page can be write-locked.
<10>	Supervisor Access Only	Restricts access to supervisory cycles only.
<11>	PCI I/O Mem Select	When clear (the default), the VMEbus master uses a PCI memory cycle to transfer VME data to the mapped main memory address. When set, it forces a PCI I/O cycle to allow a VME device access to one of the Alpha VME 5/352 or 5/480 SBC I/O resources.
<13:12>	Page Monitor	Specifies how a Alpha VME 5/352 or 5/480 SBC checks the scatter-gather map entry for access, according to the following values: 0 — No monitoring of the page. 1 — Each time the page is accessed, Monitor 1 is incremented. 2 — Each time the page is accessed, Monitor 2 is incremented. 3 — Each time the page is accessed, Monitor 3 is incremented. The counters are readable in the VME interface processor page monitor CSR (VIP_PMCSR).
<31:14>	Memory Page	Page frame number shifted left by 1.

Table 3–7 PCI Address in an Inbound Scatter-Gather Map Entry

Field	Description
<1:0>	Set to 00 to pad.
<12:2>	VME Address
<30:13>	Memory Page, that is, bits <31:14> of the VME address.
<31>	Set to 0 to force access to the lower 2 GB of PCI memory space. Configuration cycles are never initiated by the VME interface.

The PCI bus uses C/BE signals to specify which bytes are being accessed.

3.3 VME Interface Initialization

Before you can operate the VME interface, you must initialize it. The initialization procedure consists of the following steps, which are discussed in more detail in Sections 3.3.1 to 3.3.3:

1. Configure the PCI interface to the VMEbus, Section 3.3.1
2. Program scatter-gather RAM, Section 3.3.2
3. Configure the VIC64 chip, Section 3.3.3

3.3.1 Configuring the PCI Interface to the VMEbus

The first step to initializing the VME interface is to configure the PCI interface to the VMEbus. To configure the PCI interface, you must write to three PCI base address registers within the DC7407: VME_IF_BASE, VME_WINDOW_1_BASE, and VME_SG_BASE. You have the option of using a fourth register, VME_WINDOW_2_BASE, to read the hardware setting for VME_WINDOW_2 if necessary. These registers are accessible only through PCI configuration address space. Once these registers are initialized, you can use PCI memory space to set up the remainder of the VME subsystem for access to VME devices.

The 21164 address ranges for the PCI interface are as follows:

21164 addresses	87.0000.0000 – 87.0000.1FE0
PCI configuration addresses	0000.0800 – 0000.08FF

Table 3–8 lists the PCI base address registers with brief descriptions.

Table 3–8 VME PCI Base Registers

Register	PCI Configuration Address Space	Description
VME_IF_BASE	00000810	<p>Gives access to the DC7407, VIC64, and CY7C964 registers when the base address of a window in PCI memory space is written into the register. The window is a 512-byte address region in PCI memory space, aligned on a 512-byte boundary.</p> <p>Bits <31:9> are writable.</p> <p>The locations of the VME interface registers are identified as VME_IF_BASE + xxxx, representing their address in PCI memory space.</p>
VME_WINDOW_1_BASE	00000814	<p>Gives access to VME address space when the base address of a window in PCI memory space is written into the register. Only bits <31:29> are writable because the 512 MB window must be aligned on a natural boundary.</p>
VME_SG_BASE	00000818	<p>Gives access to scatter-gather RAM when the base address of a 128 KB window in PCI memory space is written into the register.</p>
VME_WINDOW_2_BASE	0000081C	<p>Gives access to VME address space when the base address of a second window in PCI memory space is written into the register. Only bits <31:26> are writable because the 64 MB window must be aligned on a natural boundary.</p>

3.3.2 Programming Scatter-Gather RAM

The scatter-gather RAM is a page in memory space that is 32K x longword in size. The top 27 bits are read/write; the remaining 5 bits are MBZ. Scatter-gather RAM is not initialized by the hardware and starts in a random state. The operating system must initialize this area to a default state before the VME subsystem can be used.

The scatter-gather RAM is fully programmable over the PCI bus. The mapping of the scatter-gather RAM takes up 128 KB of PCI memory space and has its own base address.

To configure the VME interface for both master and slave operation, the scatter-gather entries for both inbound and outbound accesses must be programmed to provide address translation between the VMEbus and the PCI bus. The scatter-gather RAM can be programmed independently of master or slave VMEbus activity.

The 8K scatter-gather longword entries are in three regions:

Entry	Address Region	Each Entry Maps	Index Formed By
2048 A24 inbound	VME_SG_BASE + 0x10000	8K page of A24 VME address space into PCI address space	VME A24 <23:13>
16384 A32 inbound	VME_SG_BASE	8K page of A32 VME address space into PCI address space	VME A32 <26:13>
2048 outbound	VME_SG_BASE + 0x1E000	256K page of PCI memory into VMEbus	Depends on region used for master access: VME_WINDOW : PCI <28:18> VME_SUB_WINDOW (64 MB): PCI <25:18>

3.3.3 Configuring the VIC64 Chip

The address map for the VIC64 chip places the VIC registers in byte 3 of a particular longword address. As used by an Alpha VME 5/352 or 5/480 SBC, the VIC registers are seen at byte 0 in each longword when accessed over the PCI bus.

The rest of this section provides some guidance for configuring the VIC64 chip by describing the bit fields of the VIC registers. Some timing control register values are defined.

For descriptions of the VIC64 chip registers, see the *VIC64 Specification*.

VICR

- Bits 2-0 Local interrupt priority level (IPL) setting for VMEbus interrupter acknowledge received interrupt.
- Bits 6-3 Reserved, must read as 1s.
- Bit 7 Interrupt mask bit.

VICR1-7

- Bits 2-0 Local IPL setting for VMEbus interrupt.
- Bits 6-3 Reserved, must read as 1s.
- Bit 7 Interrupt mask bit.

DMASICR

- Bits 2-0 Local IPL setting for end of DMA interrupt.
- Bits 6-3 Reserved, must read as 1s.
- Bit 7 End of DMA interrupt mask bit.

LICR1-7

- Bits 2-0 Local IPL setting for LIRQ interrupt line.
- Bit 3 Indicates voltage level at LIRQ pin.
- Bit 4 Autovector enable. Must be set in the Alpha VME 5/352 or 5/480 SBC.

Bit 5	Edge/level enable for LICR2 and LICR7. Must be clear in the Alpha VME 5/352 or 5/480 SBC.
Bit 6	Polarity set for LICR2 and LICR7. Must be clear in the Alpha VME 5/352 or 5/480 SBC.
Bit 7	Local interrupt mask bit.
ICGSICR	
Bits 2-0	Local IPL for global switch interrupts.
Bit 3	Reserved, must read as 1.
Bits 7-4	Interrupt mask bit for ICGS <3:0>.
ICMSICR	
Bits 2-0	Local IPL for module switch interrupts.
Bit 3	Reserved, must read as 1.
Bits 7-4	Interrupt mask bit for ICMS <3:0>
EGICR	
Bits 2-0	Local IPL for error group interrupts.
Bit 3	SYSFAIL asserted (read only).
Bit 4	SYSFAIL interrupt mask.
Bit 5	Arbitration timeout interrupt mask.
Bit 6	VIC/CY write post fail interrupt mask.
Bit 7	AC fail interrupt mask.
ICGSIVBR	
Bits 1-0	Read only.
Bits 7-2	User defined. Combines with ICGS switch number to provide vector.
ICMSIVBR	
Bits 1-0	Read only.
Bits 7-2	User defined. Combines with ICMS switch number to provide vector.
LIVBR	
Bits 1-0	Read only.
Bits 7-2	User defined. Combines with LIRQ number to provide vector.
EGIVBR	
Bits 1-0	Read only.
Bits 7-2	User defined. Combines with fixed codes to provide vector.
ICFSR	
Bits 3-0	Module switches.
Bits 7-4	Global switches
ICR0-4	General-purpose registers. Accessible over the VMEbus or local bus.
ICR5	Read-only register containing the VIC64 revision. Accessible over VMEbus or local bus.
ICR6	
Bits 1-0	Read only from the VMEbus. Must be cleared by the processor after reset.
Bits 5-2	Reserved, must read as 1s.
Bit 6	Must be cleared by the processor after reset. If enabled by LICR7, this bit being set asserts SYSFAIL* on the VMEbus.
Bit 7	Read only.
ICR7	

Bits 4-0	Read and write from the VMEbus or local bus. These bits are set if the corresponding ICR is written.
Bit 5	Read only.
Bit 6	HALT and RESET control.
Bit 7	VME SYSFAIL* mask, must be set after reset if resets are not to be translated into SYSFAIL* assertion.
VIRSR	
Bit 0	Enable VMEbus interrupter.
Bits 7-1	If bit 0 is set during the write that sets a bit, the corresponding VMEbus interrupt is asserted. These bits are cleared if bit 0 is cleared during the write that sets a bit.
VIVBR1-7	Each register sets the vector returned on VMEbus interrupt acknowledge cycles at that interrupt level.
TTR	
Bit 0	Set to include VMEbus acquisition time in local bus timeout.
Bit 1	When VME interface is used as system controller, this bit is set to indicate arbitration timeout.
Bits 4-2	Recommended timeout period for local bus is 64 μs (011).
Bits 7- 5	Recommended timeout period for VMEbus is 128 μs (100).
	The use of timeout periods depends on the VME environment. When the Alpha VME 5/352 or 5/480 SBC is a system controller and a cycle times out on the local bus after timing out on the VMEbus, the cycle hangs. To avoid this condition, set the timeout period for the local bus first or not at all.
LBTR	
Bits 3-0	Minimum PAS assertion time. Keep the default of zero.
Bit 4	Minimum DS deasserted time. Must be set in the Alpha VME 5/352 or 5/480 SBC.
Bits 7-5	Minimum PAS deasserted time. Must be binary 110.
BTDR	
Bit 0	Dual Path enable. Must be set.
Bit 1	AMSR register. Sets up user-defined address modifier codes for block mode transfers.
Bit 2	Local bus 256 bus byte boundary. Recommend this be set.
Bit 3	VME 256 bus crossing enabled. Recommend this be set.
Bit 4	Enables D64 master operation.
Bit 5	Enable enhanced turbo mode. Must be clear.
Bit 6	Enables D64 slave operation. Recommend this be set.
Bit 7	Enable 2 KB boundary crossing for D64. If set, software must check that the D64 block mode transfer start address is 2 KB aligned and that the transfer does not cross a 64 KB boundary.
ICR	
Bit 0	Read-only system controller pin.
Bit 1	Turbo enable. Must be clear.
Bit 2	Metastability delay. Recommend this be clear.
Bits 4,3	Deadlock signaling. Must be clear.
Bits 5-7	RMC control bits 1 to 3.
ARCR	

Bits 3-0	VMEbus fairness timer enable.
Bit 4	DRAM refresh enable. Must be clear.
Bits 6,5	VMEbus request level.
Bit 7	Arbitration mode.
AMSR	Defines response top and generation of user-defined address modifier codes.
BESR	All 8 bits are flags set by the VIC after status conditions that must be cleared by the processor.
DMASR	
Bit 0	Block transfer in progress. Once set, must be cleared by processor.
Bit 1	LBERR during DMA transfer.
Bit 2	BERR during DMA transfer.
Bit 3	Local bus error.
Bit 4	VMEbus BERR.
Bit 5,6	Reserved, read as 1s.
Bit 7	Master write post information stored in CYs.
SS0CR0	
Bits 1-0	Accelerated transfer mode. Must be set to binary 10.
Bits 3,2	Must be binary 01 for A24 slave selection.
Bit 4	D32 enable. Must be set in the Alpha VME 5/352 or 5/480 SBC.
Bit 5	Supervisor access.
Bits 7,6	Periodic timer enable. Must be binary 00.
SS0CR1	Local bus timing values. Must be 0x00.
SS1CR0	
Bits 1-0	Must be set to binary 10, accelerated transfer mode.
Bits 3,2	Must be binary 00 for A32 slave selection.
Bit 4	D32 enable. Must be set.
Bit 5	Supervisor access.
Bit 6	VIC/CY master write posting enable. Recommend this be clear.
Bit 7	Slave write post enable. Must be clear.
SS1CR1	Local bus timing values. Must be 0x00.
RCR	
Bits 5-0	Block transfer burst length.
Bits 7,6	VMEbus release mode.
BTCR	
Bits 3-0	Interleave period. Recommend a value of 0xF.
Bit 4	Data direction bit: 0=write, 1=read
Bit 5	MOVEM enable. Recommend this be clear.
Bit 6	BLT with local DMA enable.
Bit 7	Module based DMA transfer enable.
BTLR1-0	Registers for block transfer length for local DMA block mode transfers.
SRR	System reset register.

3.4 Requesting Ownership of the VMEbus

Before an Alpha VME 5/352 or 5/480 SBC can act as the VMEbus master, the VME interface for that system must request ownership of the bus. Controlling the manner and level of the bus request is achieved using the VIC arbiter/requester configuration register (VIC_ARCR). See the *VIC64 Specification* for a description of this register. For more information about VMEbus arbitration, see Section 3.6.1.

3.5 VME Data Transfers

As a VME master, Alpha VME 5/352 and 5/480 SBCs support data transfers in two ways:

- Single transfers: D08, D16, D32 data size
- Block transfers: D16, D32, D64 data size

3.5.1 Single Mode Transfers

Single D08, D16, and D32 data transfers are executed by individual accesses to either of the two VME address windows in PCI memory space. The data size for the VME transfers are derived from the byte-enabling of the corresponding PCI cycle.

3.5.2 Block Mode Transfers

A block mode DMA engine in the VME interface can be programmed to transfer up to 64 KB without processor intervention in D16, D32, or D64 format. The interface handles the segmentation of the transfer so as not to violate the VMEbus specification for crossing VME address boundaries.

3.5.3 Setting Up for Block Mode Transfers

To set up for block mode transfers, you must define the following:

- Transfer length
- Data size
- Transfer direction
- Source address
- Destination address

3.5.4 Setting Up for Block Mode DMA Transfers

To set up for block mode DMA transfers:

1. Define the transfer length and data size.

Write the DMA transfer length to the VME byte length registers, VIC_BTLR0 and VIC_BTLR1. You can enable PCI deferred write operations to decouple the CPU from the delays on the local bus. To distinguish

D64 block mode operations write to bit 4 of the VIC64's block transfer definition register (VIC_BTDR). The transfer length must be even as D08 block mode is not supported.

2. Define the transfer direction.

Set (read) or clear (write) the DMA direction bit and set the DMA enable bit of the VIC block transfer control register (VIC_BTCR).

3. Define the source and destination addresses.

Write the required PCI start address (as the write data) to the desired PCI memory address.

4. Enable DMA transfers.

Clear the DMA enable bit in the VIC_BTCR register.

5. Wait for completion notification.

Wait for notification that the transfer completed. The completion interrupt is enabled in the VIC status register (VIC_DMAICR) and its vector is generated by the VIC error group interrupt vector address register (VIC_EGIVBR).

The mapping of PCI memory to VMEbus addresses is handled as usual through the scatter-gather mapping mechanism, however, the address modifiers in the mapping entry are automatically transformed to generate the block-mode version of the specified address modifier code (except for user-defined address modifier codes).

For descriptions of the VIC64 chip registers, see the *VIC64 Specification*.

Restrictions

The following restrictions apply to VME master block-mode transfers:

- Master block mode D64 transfers that do not start on naturally-aligned 2K boundaries on the VMEbus require some special care. If a 2 KB boundary crossing is enabled (**VIC_BTDR<7>** = 1), the VME starting address must be aligned to a 2 KB boundary.
- The PCI address must not cross a 64 KB aligned boundary. Usually, the operating system's DMA interface handles this restriction.

Programming Arbitration Delays for Slave Access

Because the VMEbus specification prohibits crossing any 256/2 KB boundaries, any DMA transfer must be split into multiple bus transfers. At the interval between these transfers, the VME interface can be programmed to wait a period of time before arbitrating again for the VMEbus and proceeding. This delay gives VME slaves the opportunity to complete accesses during a block-mode transfer. This interleave period is programmable in the VIC block transfer control register (VIC_BTCR). For a description of this register, see the *VIC64 Specification*.

Programming the Burst Length of DMA Transfers

The maximum burst length of a DMA block mode transfer is 256/2K. By using the VIC release control register (VIC_RCR) you can program the VMEbus to use a shorter burst length. For a description of the VIC_RCR, see the *VIC64 Specification*.

3.5.5 VME Interprocessor Communication

The VIC64 chip has two sets of registers that allow communication between processors: communication registers and software switches. The software switches include global switches and module switches. Use of the interprocessor communication register (ICR) sets is restricted to only one set at a time.

The registers are accessible in the VME interface register space mapped in PCI memory space. When accessed over the VMEbus, they are located in A16 space by byte 1 of the VMEbus i/f address base register (VIF_ABR). They are also accessible from PCI memory space starting at address VME_IF_BASE + 0x60.

3.5.5.1 Interprocessor Communication Registers

Five of the general-purpose ICRs are 8-bit read/write registers accessible over the VMEbus and in local PCI memory space. Two others allow VIC64 status and hardware revision information to be read over the VMEbus.

Bits <4:0> in the final register are set when there is a write access to the corresponding ICR. For mapping of the registers, see the *VIC64 Specification*.

3.5.5.2 Interprocessor Communication Global Switches

The interprocessor communication global switches (ICGSs) are software switches that you can set over the VMEbus (not locally accessible over the PCI bus) to interrupt a group of VMEbus modules that share an A16 base address.

Because the global switches are meant to be issued to several modules, the slave targets of a global switch access do not acknowledge the cycle. Instead, the master driving the write data transfer acknowledgements (DTACKs) acknowledges the cycle itself (the VIF_ABR register should be set to generate a self-access by the global-switch write).

A write to an even address clears the selected switch and a write to an odd address sets the switch.

If global-switch interrupts are enabled in the VIC64 interprocessor communication global switch interface configuration register (ICGSICR), an interrupt is generated to the local processor by way of the system interrupt controller. The vector for the interrupt is generated from the VIC64 interprocessor communication global switch interface vector base register (ICGSIVBR).

Bits <4:0> in the final register are set when there is a write access to the corresponding interprocessor communication group processor register (ICGPR).

For a mapping of the ICGS switches, see the *VIC64 Specification*.

3.5.5.3 Interprocessor Communication Module Switches

The interprocessor communication module switches (ICMSs) are software-writable switches that can be set over the VMEbus to interrupt a processor. The module switches, however, are meant to be issued to a specific module.

Because the module switches are meant for a specific module, the cycle is just like a normal write on the bus (unlike for the global switch interface).

If interprocessor communication module-switch interrupts are enabled in the VIC64 interprocessor communication module switch interface configuration register (ICMSICR), an interrupt is generated. The vector for the interrupt is generated from the VIC64 interprocessor communication module switch interface vector base register (ICMSIVBR).

For a mapping of the ICMS switches, see the *VIC64 Specification*.

3.6 System Controller Operation

An Alpha VME 5/352 or 5/480 SBC can operate as a full VMEbus system controller (in slot 1). The SBC is selected as a system controller at power-up by the state of the module diagnostic-in-progress switch (position 4 closed).

As a system controller, the SBC can:

- Reset the VME interface logic
- Control VMEbus arbitration (drive BGIOUT*)
- Drive the system clock (SYSCLK)
- Control timeout timers for data transfers and arbitration
- Handle VMEbus interrupt control (by driving IACK*)

The system controller functions are controlled through byte registers that are mapped into the lowest byte of an aligned longword in PCI memory space.

3.6.1 Controlling VMEbus Arbitration

As system controller the Alpha VME 5/352 or 5/480 SBC can control VMEbus arbitration. The arbitration scheme that is to be used is determined by bit settings in the arbiter/requester configuration register (VIC_ABR, offset B0) and the VMEbus request lines. Possible arbitration schemes include:

- Priority (PRI)
- Round-robin (RRS)
- Single-level (SGL)

For a description of the VIC_ABR register and more detail on bit settings for the various arbitration schemes, see the *VIC64 Specification*.

3.6.1.1 Requesting the VMEbus

The granting of ownership of the VMEbus to a master is passed down the VMEbus along a daisy-chain. Because of this arrangement, the masters further down the daisy-chain can be blocked by masters higher up the chain. This problem (bus

starvation) can be minimized if the masters all implement a Fair Request scheme. If any master does not obey the fairness scheme, it can starve the masters further along the daisy-chain.

Under the Fair Request scheme, the Alpha VME 5/352 and 5/480 SBCs do not request the VMEbus for the duration of a fairness timeout period, if any other master is requesting the VMEbus. When the timeout period expires, the SBC asserts its request regardless of other requests. The fairness timeout period gives any other masters along the daisy-chain the opportunity to win the VMEbus.

3.6.1.2 Releasing the VMEbus

Once an Alpha VME 5/352 or 5/480 SBC has acquired ownership of the VMEbus, it is important to control the manner in which the bus is relinquished. Four release modes are supported:

- Release-on-request (ROR)
- Release-when-done (RWD)
- Release-on-clear (ROC)
- Bus capture and hold (BCAP)

You configure the release mode in the VIC release control register (VIC_RCR, offset D0).

In addition to these four bus release modes, you can use the scatter-gather RMW bit (RMC) to force the Alpha VME 5/352 or 5/480 SBC to hold ownership of the VMEbus for two accesses before releasing in the programmed ROR, RWD, or ROC fashion.

For a description of the VIC_RCR register, see the *VIC64 Specification*.

3.6.2 Controlling the System Clock

As the system controller, an Alpha VME 5/352 or 5/480 SBC drives the system clock (SYSCLK) for the VMEbus. The clock is a fixed 16 MHz clock with a nominal 50% (+/- 10%) duty cycle. This 16 MHz timing has no fixed phase relationship with other bus timings.

3.6.3 Controlling Timeout Timers

As system controller, an Alpha VME 5/352 or 5/480 SBC can control the following timers:

- Arbitration timers
- VMEbus transfer timers
- Local bus transfer timers

3.6.3.1 Arbitration Timers

By default, an Alpha VME 5/352 or 5/480 SBC operates as an arbitration watchdog when configured as VMEbus system controller. After issuing a VMEbus grant to the winning requester, the VME interface monitors the bus and, if it does not detect activity (BBSY* asserting) within 8 microseconds, it asserts the BBSY* signal to terminate the bus ownership and to allow re-arbitration. You can-

not disable this arbitration timeout. However, you can use the condition to generate a local interrupt to the processor. You can control this interrupt by using the VIC64 error group interrupt control register (VIC_EGICR). For more information, see the *VIC64 Specification*.

3.6.3.2 VMEbus Transfer Timers

When enabled, the VME interface starts the transfer timer whenever the data phase of a cycle is signaled (DSx* asserting). If the timer expires before the data cycle is acknowledged or completes in error, the VME interface, as system controller, flags a VMEbus error (asserting BERR*). This condition sets a status bit in the VIC64 error status register (VIC_BESR).

The transfer timeout is configured in the VIC64 transfer timeout register (VIC_TTR, offset 0xA0). For a description of this register, see the *VIC64 Specification*.

3.6.3.3 Local Bus Transfer Timer

When enabled, the local bus transfer timer starts whenever a data phase is initiated on the local bus (the bus between the VIC64 and DC7407 chips). If the timer expires before the data cycle is acknowledged or terminated by an error, the VME interface signals a local bus timeout. This condition sets a status bit in the VIC64 error status register (VIC_BESR).

3.6.4 Handling VMEbus Interrupts

An Alpha VME 5/352 or 5/480 SBC can act as a VMEbus interrupter as well as a VMEbus interrupt servicing agent. As system controller, the SBC drives the IACK daisy-chain if the VIC64 chip has no VME interrupt pending.

The VIC interrupt request/status register (VME_IF_BASE + 0x80) provides the current state of the SBC's interrupt request lines (IRQ1*-7*), which are driven onto the VMEbus. For a description of this register, see the *VIC64 Specification*.

An Alpha VME 5/352 or 5/480 SBC uses the Release-On-Acknowledge method for removal of its interrupt requests. As an alternative, the interrupt requests can be deasserted by writing to the same VMEbus interrupt request/status register that is used to assert the interrupt request lines. When the SBC detects an IACK cycle on the VMEbus for one of its interrupt requests, it responds with a vector that is programmable in the VMEbus interrupt vector base registers, starting at PCI memory address VIF_ABR+0x84.

A local interrupt can be generated to the CPU by the VME interface when it detects a VMEbus IACK cycle for a VME interrupt that is pending. This interrupt can be used to inform system software that the VMEbus interrupt request has been serviced. The VIC interrupter interrupt control register (VME_IF_BASE + 0x00) provides enabling of priority encoding for this interrupt.

3.7 Byte Swapping

DIGITAL Alpha VME 5/352 and 5/480 SBCs support four modes of byte-swapping for transfers to and from the VMEbus. The swap mode is defined for each inbound or outbound page by the related scatter-gather map entry.

3.7.1 DC7407 Byte Swapping

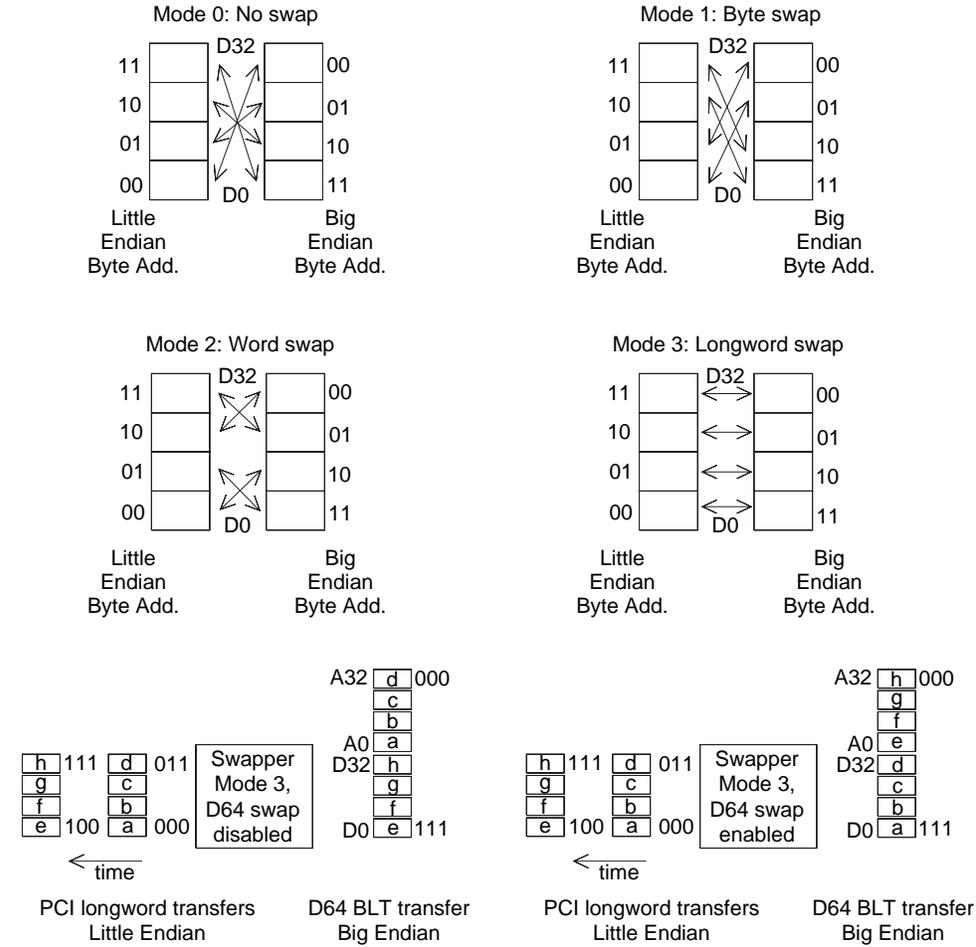

The swap mode for each scatter-gather map entry is defined by 3 bits, **SWP<2:0>**. Bits <1:0> define mode 0 through 3 and **SWP<2>** enables D64 swapping, which is only used in D64 block mode data transfers.

Table 3–9 describes the swap modes and Figure 3–7 shows them graphically with the D64 swap cases illustrated with mode 3.

Table 3–9 Swap Modes

Mode	Type of Swap	Description
0	No Swap	No bytes are swapped, and in transferring bytes from the little endian PCI to the big endian VMEbus, the address of any byte as seen on the two buses remains the same.
1	Byte Swap	The bytes within words are swapped.
2	Word Swap	The words within longwords are swapped.
3	Longword Swap	Combination of modes 1 and 2. Byte 11 in a longword becomes byte 00, 10 becomes 01, 01 becomes 10, and 00 becomes 11.
	D64 Swap	Used only in D64 block mode transfers. Swaps the order that the longwords are taken from or put into memory over the PCI bus. For example, when enabled with a mode 3 swap, byte 000 in a quadword becomes byte 111, that is, the binary byte address is inverted.

Figure 3–7 Swap Modes

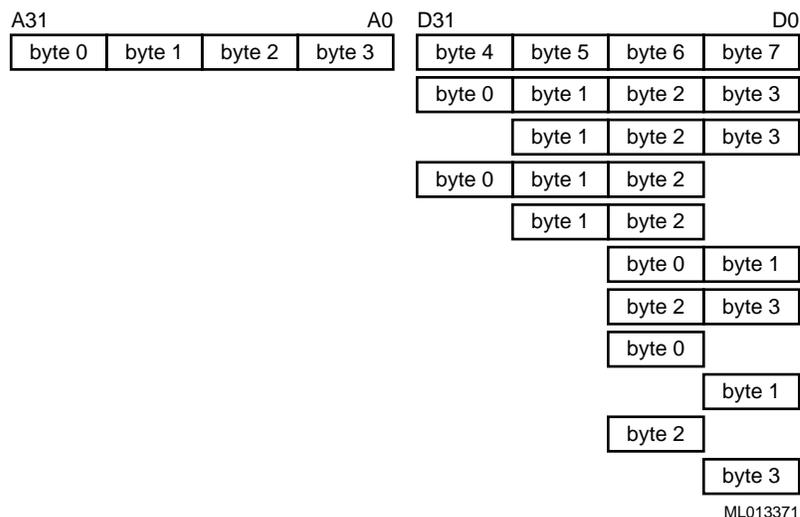

D64 swap illustrated in combination with mode 3 longword swap.

ML013307

3.7.2 VIC64 Byte Swapping

When transfers of less than complete longwords are done to or from the VMEbus, the VIC64 chip, as a VMEbus master, drives the data to and from the VMEbus. The data must be driven to certain VMEbus lanes depending on the data width. This is shown in Figure 3–8.

Figure 3–8 Big Endian VME Byte Lane Formats

ML013371

The longword transfers, tribyte transfers, and unaligned word transfers use the byte lanes in the same way. However, when the low word in a longword is transferred, the data is switched to or from its usual lanes **D<31:16>** to or from **D<15:0>**. Byte transfers in the low word of a longword are swapped in a similar way.

The single data transfers, D64, are a special case. The VIC64 chip packs the data to form quadwords in the CY7C964 chips and on the VMEbus. Only full quadword block mode transfers are allowed in D64 mode.

Table 3–10 shows the local bus address and size signals used for the DC7407 chip’s swap modes when that chip is master of the local bus. When consulting the table, keep the following in mind:

- Cycles in which data moves to or from the D0-16 lane are marked with “L”.
- Cycles that would cause a noncontiguous arrangement of bytes on the VMEbus are not allowed and are aborted on the PCI bus.
- No cycles are generated for PCI transfers with noncontiguous PCI byte enables, but these cycles are included in the table for completeness.

Table 3–10 PCI BE# to Local A1,0 and SIZ1,0 Translation for Swap Modes

PCI BE# <3:0>	Mode 0 No Swap A1,0SIZ1,0	Mode 1 Byte Swap A1,0 SIZ1,0	Mode 2 Word Swap A1,0 SIZ1,0	Mode 3 Longword Swap A1,0 SIZ1,0
1111	No cycle	No cycle	No cycle	No cycle
1110	00 01	L 01 01	L 10 01	11 01
1101	01 01	L 00 01	L 11 01	10 01
1011	10 01	11 01	00 01	L 01 01 L
0111	11 01	10 01	01 01	L 00 01 L
1100	00 10	L 00 10	L 10 10	10 10

As a VMEbus slave or during DMA-driven block mode transfers, the VIC64 chip drives the local bus address lines and the DC7407 chip generates the byte-enable combinations to drive onto the PCI bus. In some cases, the translations may result in noncontiguous byte-enable arrangements on the PCI bus. These are passed to the PCI bus with the corresponding byte enables asserted. As Table 3–11 shows, the data for byte and aligned words is always received on the data lines D[15:0].

System Interrupts

This chapter discusses the following:

- An overview of system interrupts, Section 4.1
- Interrupts handled by the Xilinx controller, Section 4.2
- Interrupts handled by the VIC64 chip, Section 4.3
- Interrupts handled by the SIO chip, Section 4.4
- Module resets, Section 4.5

4.1 Overview of System Interrupts

The 21164 microprocessor uses seven interrupt request lines. The seven interrupt request lines are identical, asynchronous, level-sensitive, and can be masked individually by PALcode. Table 4–1 lists each interrupt request line with its assigned interrupt source and the types of interrupts it handles.

Table 4–1 CPU Interrupt Assignments

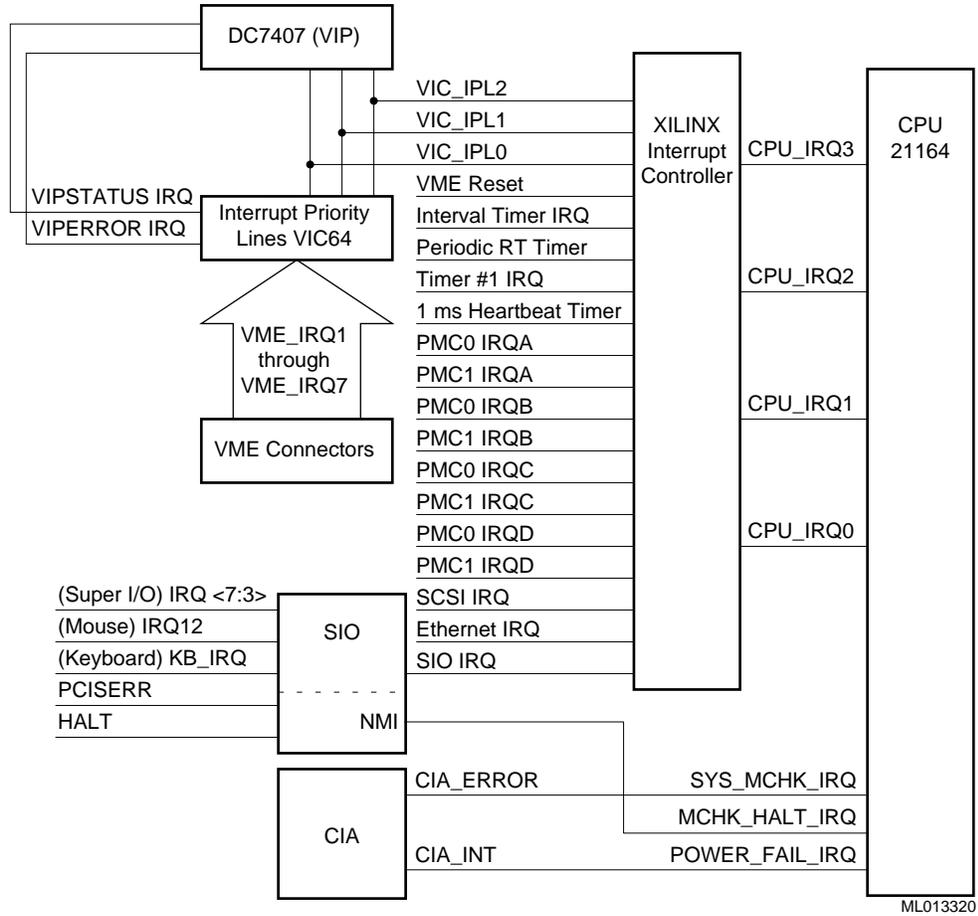

CPU Interrupt Request Line	Interrupt Source	Types of Interrupts Handled
CPU_IRQ0	Interrupt registers 3 and 4	PCI device interrupts from SCSI devices, Ethernet controllers, multi-function PMC options, the SIO chip, and VME interrupts [3:1]
CPU_IRQ1	Interrupt register 2	PCI device INTA interrupts from PMC options and VME interrupts [6:4]
CPU_IRQ2	Interrupt register 1	VIP location monitor status and the 1 ms heartbeat timer
CPU_IRQ3	Interrupt register 1	Interval timer, VMEbus reset, VMEbus interrupt 7, VIP/VIC error and status, and periodic real-time timer
MCHK_HALT_IRQ4	82378	SIO chip nonmaskable interrupt
SYS_MCHK_IRQ	21172-CA	CIA Chip
CIA_INT		

Figure 4–1 shows a schematic overview of how the Alpha VME 5/352 and 5/480 SBCs handle interrupts. As the figure shows, interrupts are routed to the CPU through the following interrupt controllers:

- Xilinx interrupt controller
- VIC64 chip system interrupt controller

- SIO chip programmable interrupt controller

Figure 4–1 Block Diagram of the Interrupt Logic

ML013320

4.2 Interrupts Handled by the Xilinx Controller

Four interrupt/mask registers in the Xilinx field-programmable gate array (FPGA) generate the interrupt requests that the CPU receives on interrupt request lines 0 through 3.

Table 4–2 Mapping of Interrupt/Mask Registers to Interrupt Request Lines

Register	Bits	Interrupt Request Line
Interrupt/mask 1	<0> - VME reset	CPU_IRQ3
	<1> - VME interrupt priority level 6	
	<2> - Interval timer	
	<3> - Periodic heartbeat timer	
	<4> - VME interrupt priority level 5	
Interrupt/mask 2	<5> - 1 ms heartbeat timer	CPU_IRQ2
	<0> - VME interrupt priority level 4	CPU_IRQ1
<1> - PMC 0 interrupt request A		
Interrupt/mask 3	<2> - PMC 1 interrupt request A	
	<0> - VME interrupt priority level 5	CPU_IRQ0
	<1> - SIO interrupt request	
	<2> - Ethernet controller interrupt request	
	<3> - SCSI controller interrupt request	
	<4> - PMC 0 interrupt request B	
	<5> - PMC 1 interrupt request B	
	<6> - PMC 0 interrupt request C	
<7> - PMC 1 interrupt request C		
Interrupt/mask 4	<0> - PMC 0 interrupt request D	CPU_IRQ0
	<1> - PMC 1 interrupt request D	

You can mask each interrupt individually by setting the appropriate bit in the interrupt/mask register. Interrupts that the VME subsystem generates also need to be masked in the VIC64 chip. Disable an interrupt by writing a 1 to the appropriate bit position in the interrupt/mask register. Enable an interrupt by writing 0 to the appropriate bit position.

To check the state of the interrupts associated with a specific interrupt/mask register, read the register. A read operation returns the state of the interrupts regardless of which mask bits are set. A 1 indicates that the interrupt source has asserted an interrupt.

For more detail on the interrupt/mask registers, see Section 5.4.3.3.

4.3 Interrupts Handled by the VIC64 Chip

The VIC64 chip system interrupt controller handles 19 interrupt sources. You can program each source individually to any of seven interrupt priority levels (IPLs). The chip stores an IPL in an interrupt control register (ICR). Table 4–3 shows the fixed relative ranking for interrupt requests that the chip uses to decide which interrupt is to be reported if multiple interrupts are pending.

Table 4–3 VIC64 Chip Interrupt Ranking

Rank	Interrupt	CSRs
19	DC7407 error	VIC_LICR7, VIC_LIVBR
18	VME interface status or error	VIC_EGICR, VIC_EGIVBR
17	Not used	
16	Not used	
15	Not used	
14	Not used	
13	DC7407 status	VIC_LICR2, VIC_LIVBR
12	Not used	
11	Interprocessor communications global switch	VIC_ICGSICR, VIC_ICGSIVBR
10	Interprocessor communications module switch	VIC_ICMSICR, VIC_ICMSIVBR
9	VMEbus IRQ7*	VIC_IRQ7ICR
8	VMEbus IRQ6*	VIC_IRQ6ICR
7	VMEbus IRQ5	VIC_IRQ6ICR
6	VMEbus IRQ4*	VIC_IRQ6ICR
5	VMEbus IRQ3*	VIC_IRQ6ICR
4	VMEbus IRQ2*	VIC_IRQ6ICR
3	VMEbus IRQ1	VIC_IRQ6ICR
2	DMS status	VIC_DSICR, VIC_EGIVBR
1	VME IACK	VIC_IICR, VIC_EGIVBR

The VIC64 chip passes VME interrupts to the CPU by way of the interrupt/mask registers. When the CPU identifies a VME interrupt, the CPU initiates a read of the VIP_IRR register to retrieve the interrupt vector from the VIC/DC7407. This read operation generates a local bus interrupt acknowledge (IACK) cycle at the pins of the VIC64 chip. When the chip detects the IACK cycle, the chip responds by returning the vector and IPL of the highest ranking active interrupt request to the CPU. (The vector is pre-pended, using bits <10:8>, with the IPL of the interrupt.)

4.3.1 Local Device Interrupts

The VIC64 chip can support up to seven interrupt sources. In Alpha VME 5/352 and 5/480 SBCs, however, the chip supports only the following two sources:

- DC7407 VIP status
- DC7407 VIP errors

Each of the interrupt sources has an associated interrupt control register (ICR) and vector register. You can use the ICRs to disable interrupts of a particular source or assign IPLs. Bit <7> disables the interrupt source. Bits <3:0> specify the IPL.

The vectors associated with the interrupt sources consist of eight bits and have a single common root that is modified so each device has a unique vector. Bits <7:3> of a given vector are programmable, while bits <2:0> uniquely identify an interrupt.

4.3.2 VMEbus Interrupts

When configured as the system controller, the VIC64 chip handles the standard 7-level prioritized interrupt scheme of the VMEbus.

Within the system, VMEbus interrupts compete (based on IPL and ranking) with other system interrupts. If, during a local bus interrupt acknowledge (IACK) cycle, a VMEbus interrupt source is selected for processing, the VIC64 chip initiates a VMEbus IACK cycle to retrieve the vector of the source that interrupted the bus from the VIP_IRR register. The vector is then passed to the 21164 microprocessor.

It is assumed that a VMEbus interrupt source releases the interrupt request line when it receives the VMEbus IACK or as a result of the action (write to register, and so forth) of the interrupt service routine (ISR).

4.3.3 Status/Error Interrupts

Internal to the VIC64 chip are conditions and errors that can be reported as an interrupt request. In the case of the following conditions, you have the option of enabling them to generate system interrupts:

- VMEbus SYSFAIL* assertion
- VMEbus ACFAIL* assertion
- VMEbus arbitration timeout
- VIC64 write post failure
- DMA completion
- VMEbus IACK cycle in response to a VMEbus interrupt generated by the CPU

The first four conditions in the preceding list use the VIC64 error group ICR (VIC_EGICR), which is different than ICRs already discussed. In the case of this ICR, a single IPL is assigned for all events, while the higher order bits (<7:4>) allow you to disable individual conditions selectively.

The DMA status ICR (VIC_DMASICR) allows the signalling of DMA completion. If the interrupt is enabled, an interrupt is generated at a programmed IPL when DMA transactions complete.

For local (on-board) interrupts generated by the VIC64 chip (the VME interface detects a VMEbus IACK cycle to itself), the chip notifies the CPU by using the VMEbus interrupter ICR (VIC_IICR). Like with most other ICRs, you can disable the generation of local interrupts and set the IPL programmatically.

Yet another register, the VIC error group interrupt vector base register, allows you to control the reporting of DMA errors and “interrupter-sees-IACK” interrupts. The vector root of this register, bits <7:3>, are programmable while the least significant three bits vary for each of the following conditions:

Bit Settings	Condition
000	AC fail
001	Write post fail
010	Arbitration timeout
011	System failure
100	VMEbus IACK received
110	DMA completion

This arrangement of bit fields provides a unique interrupt vector for each error and status.

4.4 Interrupts Handled by the SIO Chip

The 82378 SIO chip delivers interrupts from the mouse, keyboard, and Super I/O (37C665) to the CPU’s interrupt/mask register.

For programming details of the 8259, see the SIO chip (82378ZB) and 8259 data sheets.

4.4.1 Nonmaskable System Events

In addition to Nbus device interrupts, the SIO chip also sends a nonmaskable interrupt (NMI) to CPU MCHK_HALT_IRQ.

The front panel HALT button, the watchdog HALT, and a PCI SERR are the only such nonmaskable events. These events are handled through the SIO chip, which contains a NMI control/status register that are polled to determine the NMI reason.

All NMI events should cause a jump to the console entry point without destroying the software context, and SERR should report an error. If the interrupt reason is a HALT, the firmware reads the reset reason register to see if the watchdog bit is set. If set, the HALT is treated as a “save-software-context” watchdog HALT.

The nonmaskable description refers to the CPU’s operation. PAL code never masks the NMI input pin and the events are considered highest priority. However, the SIO chip, by default, disables the generation of the interrupt to the CPU so

they must be enabled by initialization code. Also, firmware can operate in “HALT-protected” space. For this to occur, you must disable the NMI delivery either at the HIER or SIO chip level.

For more detail about the NMI control/status register, see Section 5.4.

4.4.2 CIA Interrupt

The CIA chip asserts the signal CIA_INT to notify the 21164 microprocessor that the CIA chip has corrected an ECC error. The CIA chip asserts the signal CIA_ERROR to notify the microprocessor of uncorrectable errors detected by the CIA chip. Refer to the description of the CIA_ERR_MASK register in the *Digital Semiconductor 21172 Core Logic Technical Reference Manual* for details.

4.5 Module Resets

The Alpha VME 5/352 and 5/480 SBCs can be reset by four distinct events:

- Power-up
- Front panel switch
- Watchdog timeout
- Assertion of the VMEbus **SYSRESET*** signal (if enabled)

All on-board logic, except the module-level reset reason register, are reset at the hardware level by all of these reset events.

The assertion of the VMEbus **SYSRESET*** signal generates a module reset only if Switch 3 is closed. This prevents a module configured as a VME system controller from locking into a reset state when it asserts a VME **SYSRESET*** signal under software control.

If Switch 3 is open, the VIC64 chip still resets (all internal registers return to their default state, current transactions are aborted) but the module reset is not generated. To allow detection of this condition (VIC64 chip only reset), the VME **SYSRESET*** signal is tied to interrupt and interrupt mask register 3<0>.

System Registers

This chapter provides an example of how to gain access to system registers (Section 5.1) and describes system registers associated with the following:

- Ethernet controller, Section 5.2
- SCSI controller, Section 5.3
- SIO chip (82378ZB) and Nbus, Section 5.4
- VME interface, Section 5.5

Note

This chapter does not attempt to provide descriptions of all registers associated with these components. The chapter describes only those registers that are accessible and of use to product users.

5.1 Gaining Access to System Registers

The example in this section shows how to gain access to system registers. The example shows you how to gain access to the configuration space for the system's Ethernet chip. The example shows how to determine the offsets assigned for each PCI device. Using the offsets, examine each base address register, and for each base address assigned, look at the relevant specification to find out for what the specific area is used. See the PCI specification to determine what type of space it is (for example, I/O, sparse, or dense space).

Access the DECchip 21040 configuration base address registers as follows:

```
>>>examine pcicfg:00010010 -1
pcicfg:          10010 00010101
>>>examine pcicfg:00010014 -1
pcicfg:          10014 00220100
>>>examine pcicfg:00010018 -1
pcicfg:          10018 00000000
>>>examine pcicfg:0001001c -1
pcicfg:          1001c 00000000
>>>examine pcicfg:00010020 -1
pcicfg:          10020 00000000
>>>examine pcicfg:00010024 -1
pcicfg:          10024 00000000
```

5.2 Ethernet Controller Registers

Sections 5.2.1 to 5.2.3 describe the following Ethernet controller registers:

- Ethernet controller PCI configuration register, Section 5.2.1
- Ethernet controller control/status registers, Section 5.2.2
- Ethernet ROM control/status register, Section 5.2.3

5.2.1 Ethernet Controller PCI Configuration Registers

The Ethernet controller uses PCI configuration registers to respond to read and write requests. The 21164 and PCI addresses for these registers follow:

21164 addresses	87.0001.0000 – 87.0001.00FF
PCI addresses	0000.1000 – 0000.10FF

Figure 5–1 shows the PCI configuration space addresses of each register. For complete register bit definitions, see the DECchip 21040-AA specification.

ML013282

5.2.2 Ethernet Controller Control/Status Registers

The Ethernet controller has 16 control/status registers (CSRs) that can be accessed by the PCI host bridge. The CSRs are located in PCI I/O or memory space, are quadword-aligned, and can only be accessed using longword instructions. Table 5–1 lists the registers, their meaning, and an address that reflects the offset from the control/status register base address (CBIO, CBMA). See the DECchip 21040-AA specification for more details.

Table 5–1 Ethernet Controller Control/Status Registers

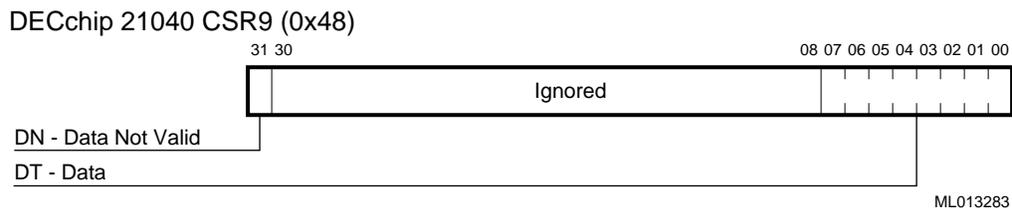

Register	Meaning	Address ₁₆
CSR0	Bus mode register	xxxx xx00
CSR1	Transmit poll demand register	xxxx xx08
CSR2	Receive poll demand register	xxxx xx10
CSR3	Rx list base address register	xxxx xx18
CSR4	Tx list base address register	xxxx xx20

CSR12	SIA status register	xxxx xx60
CSR13	SIA connectivity register	xxxx xx68
CSR14	SIA Tx Rx register	xxxx xx70
CSR15	SIA general register	xxxx xx78

5.2.3 Ethernet ROM Control/Status Register

The DECchip 21040 Ethernet controller has an Ethernet ROM control/status register (CSR9). This register can read the Ethernet ID address for an Alpha VME 5/352 or 5/480 SBC assembly from the SROM. Each read request results in 8-bit serial read cycles from the register. Write requests reset the register's pointer to its first location.

Figure 5–2 shows the Ethernet ROM control/status register.

Figure 5–2 Ethernet ROM Control/Status Register (CSR9)

5.3 SCSI Controller Registers

Sections 5.3.1 and 5.3.2 describe the following SCSI controller registers:

- SCSI controller PCI configuration registers, Section 5.3.1
- SCSI controller control/status registers, Section 5.3.2

5.3.1 SCSI Controller PCI Configuration Registers

The SCSI controller has two base address registers: one for I/O and one for memory space. This allows the 128 bytes of registers to be accessible in both the PCI memory and PCI I/O address spaces. The 21164 and PCI addresses for these registers follow:

21164 addresses	87.0002.0000 – 87.0002.00FF
PCI addresses	0000.2000 – 0000.20FF

Figure 5–3 shows the PCI configuration space addresses of each register. For complete register bit definitions, see the SCSI controller specification.

Figure 5–3 SCSI Controller PCI Configuration Registers

ML013811

5.3.2 SCSI Controller Control/Status Registers

The SCSI controller has 128 accessible byte-wide control/status registers (CSRs), as shown in Table 5–2. These registers are accessible starting at the following addresses:

- SCSI_IO_BASE in PCI sparse I/O space
- SCSI_MEM_BASE in PCI sparse memory space

For information about how to program these registers, see the PCI local bus specification.

5.4 SIO Chip and Nbus Registers

The bottom 64K of PCI sparse I/O address space is mapped onto the Nbus for use by the following:

- SIO PCI/ISA Bridge (82378ZB) registers
- SIO Chip nonmaskable interrupt control/status registers
- Module registers
- Super I/O (FDC 37C665 GT) registers
- TOY clock, watchdog timer, and NVRAM registers
- Interval timing registers

The 21164 addresses for these registers are as follows:

21164 addresses	85.8000.0000 – 85.801F.FFE0
-----------------	-----------------------------

The 21164 microprocessor can access the Nbus devices in I/O space on a byte-by-byte basis. Alpha VME 5/352 and 5/480 SBCs only support single-byte accesses to all Nbus locations.

Most resources of the Nbus are accessed as the least-significant byte of aligned longwords. The exceptions are the time-of-year (TOY) clock and the ROM. Both of these regions are contiguous bytes. When accessing the Nbus, only one PCI byte enable is asserted.

5.4.1 SIO Chip PCI Configuration Space

The SIO chip does not have any base address registers. Instead, the SIO chip negatively decodes fixed regions in both PCI I/O and PCI memory space. However, the following registers are used for PCI bus and Nbus control:

- PCI control register
- ISA controller recovery timer register
- ISA clock divisor register

The 21164 PCI configuration addresses for these register areas are as follows:

21164 addresses	87.0003.0000 – 87.0003.1FE0
PCI addresses	0000.4000 – 0000.40FF

Figure 5–4 shows the layout of the SIO chip configuration space with these registers.

5.4.1.1 PCI Control Register

The PCI control register enables the SIO chip to respond to PCI IACK cycles and to set the expected assertion speed of the DEVSEL# signal so that the subtractive decode sample point can be set. The PCI posted write buffer is also enabled. Table 5–4 lists the fields of the PCI control register.

Table 5–4 PCI Control Register

Field	Name	Description
<5>		Must be set to a 1 (default).
<4:3>		Must be set to <00> to allow slow sample point timing for negative decode.
<2>	PCI Posted Write Buffer Enable	Must be set to 1.
All other bits must be 0.		

5.4.1.2 ISA Controller Recovery Timer Register

The ISA controller recovery timer register (offset + 0x4C) is one of two byte-wide registers used as the Nbus control word.

The I/O recovery mechanism in the SIO chip is used to add recovery delay between the I/O cycles originating in the PCI bus and directed to the Nbus. Since only 8-bit cycles are supported, only bits <6:3> of the register are significant. Bits <6:3> define the number of system-clock ticks inserted between back-to-back cycles. The required value for DIGITAL Alpha VME 4 is 1001, representing one additional system-clock tick.

5.4.1.3 ISA Clock Divisor Register

The ISA clock divisor register (offset + 0x4D) is one of two byte-wide registers used as the Nbus control word. This register enables positive decode for BIOS ROM and the PCI-to-ISA clock divisor. For DIGITAL Alpha VME 4, the BIOS ROM region must not be positively decoded.

Bit <6> must be cleared and bits <2:0> must be 000 for a 32 MHz PCI system. All other bits must be 0.

5.4.2 SIO CHIP Nonmaskable Interrupt Control/Status Register

The 82378 SIO chip handles nonmaskable interrupts (NMIs), such as those generated by the front panel HALT button. The chip contains an NMI control/status register that stores NMI vectors. You can poll this register to determine the NMI reason. Figure 5-5 shows the NMI control/status register and Table 5-5 describes the register fields and settings.

Figure 5-5 Nonmaskable Interrupt Control/Status Register

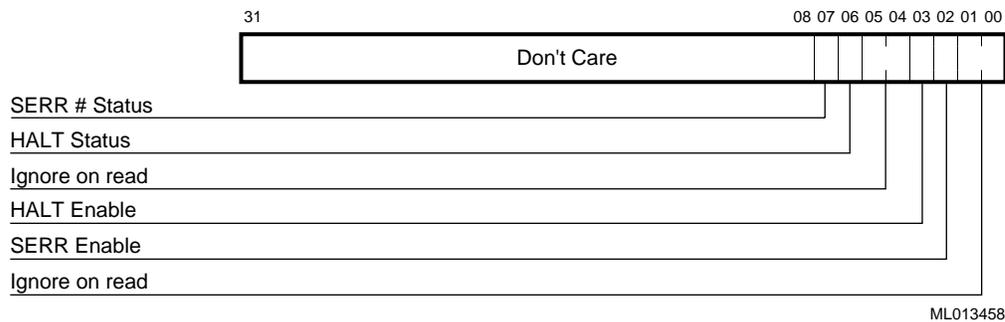

Table 5–5 Nonmaskable Interrupt Control/Status Register Bits

Field	Name	Type	Description
<7>	SERR# Status	RO	Bit <7> is set if a system SERR has occurred. The interrupt in response to this event is enabled by clearing bit <2> of this register to a 0. Bit <7> can be cleared only by setting the SERR enable bit (bit <2>) to a 1 and then back to a 0. Always write this bit as a 0.
<6>	HALT Status	RO	Bit <6> is set when either the watchdog timer expires (and is enabled) or the HALT switch is toggled. This interrupt is enabled by clearing bit <3> of this register to 0. Bit <6> should always be written as a 0. To clear this status bit, set bit <3>, and then clear it again to reenable this NMI event reporting.
<5:4>	—	R/W	Ignore on read. Writes must be 0.
<3>	HALT Enable	R/W	When set to a one, HALTs are disabled and the halt status bit in this register is cleared. When cleared (reset default), HALTs are enabled as NMI events.
<2>	SERR Enable	R/W	When set to a 1, SERR reporting is disabled and the SERR status bit in this register is cleared. When cleared (reset default), SERRs are enabled as NMI events.
<1:0>	—	R/W	Ignore on read. Writes must be 0.

Note

The SIO chip specification specifies that HALT events are reported by the SIO chip's IOCHK# pin.

All on-board logic, except the module-level reset reason register, are hardware reset by all of these reset events.

The VMEbus SYSRESET* assertion generates a module reset only if Switch 3 is closed. This prevents a module configured as a VME system controller from locking into a reset state when it issues a VME SYSRESET* under software control.

If Switch 3 is open, the VIC64 chip still resets (all internal registers return to their default state, current transactions are aborted) but the module reset is not generated. To allow detection of this condition (VIC64 chip only reset), the VME **SYS-RESET*** signal is tied to interrupt and interrupt mask register 3<0>.

5.4.3 Module Registers

Seventeen miscellaneous registers are implemented in the module logic for a variety of read/write functions. These registers are located in PCI sparse I/O space within the SIO chip address block and are listed in Table 5–6. Table 5–6 also lists the section that describes each register.

Table 5–6 Module Registers

Register	21164 Address	Nbus Offset	Section
Module display control	85.8001.0000	800	5.4.3.1
Module configuration	85.8001.0020	801	5.4.3.2
Interrupt 1	85.8001.0040	802	5.4.3.3
Interrupt 2	85.8001.0060	803	5.4.3.3
Interrupt 3	85.8001.0080	804	5.4.3.3
Interrupt 4	85.8001.00A0	805	5.4.3.3
Memory configuration 0	85.8001.00C0	806	5.4.3.4
Memory configuration 1	85.8001.00E0	807	5.4.3.4
Memory configuration 2	85.8001.0100	808	5.4.3.4
Memory configuration 3	85.8001.0120	809	5.4.3.4
Reset reason 1	85.8001.0140	80A	5.4.3.9
Memory identification	85.8001.0160	80B	5.4.3.5
Heartbeat (clear-interrupt)	85.8001.0180	80C	5.4.3.6
Module control	85.8001.01A0	80D	5.4.3.7
Reset reason 2	85.8001.01C0	80E	5.4.3.9
Bcache configuration	85.8001.01E0	80F	5.4.3.8
Reset reason 3	85.8001.05C0	82E	5.4.3.9

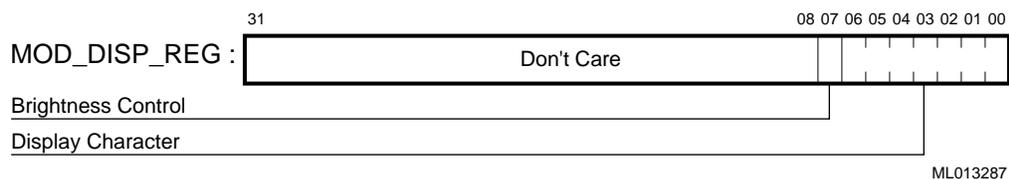

5.4.3.1 Module Display Control Register

The module display control register (MOD_DISP_REG) is read from and written to by a 5x7 dot-matrix intelligent display device. The display device supports 96 characters. The 21164 address and Nbus offset for the module display register are as follows:

21164 address	85.8001.0000
Nbus offset	800

Figure 5–6 shows the layout of the register.

Figure 5–6 Module Display Control Register

The display character is stored in bits <6:0>. The most significant bit (bit <7>) can be set to increase the brightness of the display.

Figure 5–7 shows the display’s character set. The numbers along the left-hand edge are the most-significant hexadecimal digit of the character number, while the least-significant digit is along the top. For example, the character “W” is displayed by writing a value of 0x57 to the display register. A value of 0xD7 displays “W” with full brightness.

After a system reset, the display defaults to character 0x7F (“:::”) at full brightness. During a system reset, all dots in the matrix are lit.

Figure 5–7 Display Character Set

	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
0,1	BLANK															
2	!	"	#	\$	%	&	'	()	*	+	,	-	.	/	
3	0	1	2	3	4	5	6	7	8	9	:	;	<	=	>	?
4	@	A	B	C	D	E	F	G	H	I	J	K	L	M	N	O
5	P	Q	R	S	T	U	V	W	X	Y	Z	[\]	^	_

ML013814

5.4.3.2 Module Configuration Register

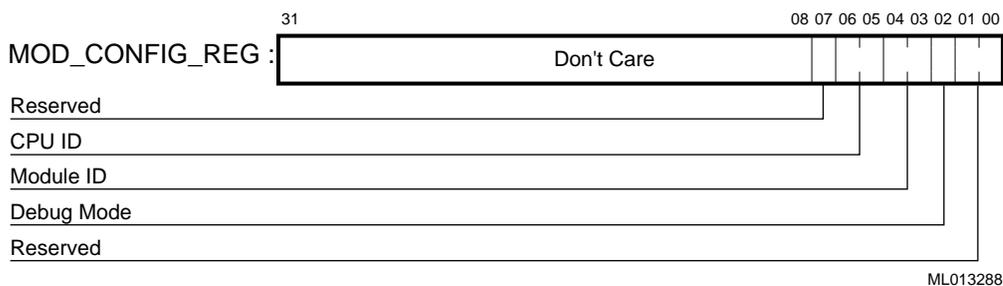

The module configuration register (MOD_CONFIG_REG) is a read-only register that contains information relating to module revision, CPU speed, and SCSI options. The information read from this register is hardwired on the module and is unaffected by resets. A write of 1 to bit 0 of this register clears the Periodic Real-Time timer.

The 21164 address and Nbus offset for the register are as follows:

21164 address	85.8001.0020
Nbus offset	801

Figure 5–8 shows the module configuration register and Table 5–7 describes the register fields.

Figure 5–8 Module Configuration Register

ML013288

Table 5–7 Module Configuration Register

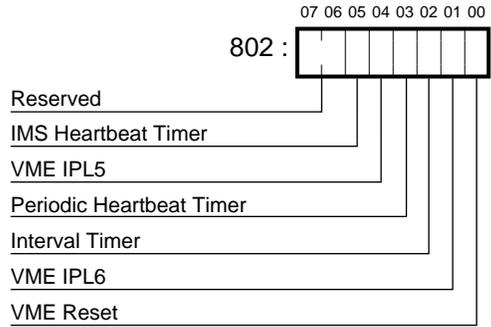

Field	Name	Type	Description
<1:0>	Reserved		
<2>	Debug	RO	If 0, the SROM starts the mini-debugger. If 1, the SROM starts the console.
<4:3>	Module ID	RO	Identifies the I/O module that is installed according to the following module definitions: 00 – Type I 01 – Type II 10 – Reserved 11 – Reserved
<6:5>	CPU ID	RO	Determines the speed of the CPU according to the following definitions: 00 – 352 MHz 01 – 480 MHz 10 – Reserved 11 – Reserved

5.4.3.3 Interrupt/Mask Registers

The `cpu_irq[3:0]` are generated by four interrupt/mask registers contained in a Xilinx FPGA, as shown in Figures 5–9 through 5–12.

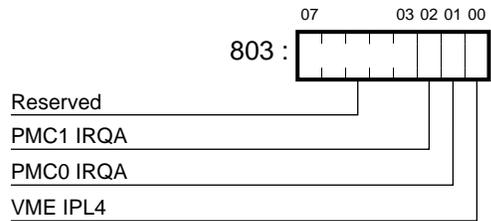

- `cpu_irq3` is controlled by bits [3:0] in interrupt/mask register 1
- `cpu_irq2` is controlled by bits [5:4] in interrupt/mask register 1
- `cpu_irq1` is controlled by bits [2:0] in interrupt/mask register 2
- `cpu_irq0` is controlled by bits [7:0] in interrupt/mask register 3 and bits [1:0] in the interrupt/mask register 4

5.4.3.4 Memory Configuration Registers 0, 1, 2, and 3

The memory configuration registers are read-only registers that store the presence detect (PD) bits of the main memory DIMMs. The 21164 addresses and Nbus offsets for registers 0 through 3 are as follows:

Memory Configuration Register	21164 Address	Nbus Offset
0	85.8001.00C0	806
1	85.8001.00E0	807
2	85.8001.0100	808
3	85.8001.0120	809

Figure 5–13 shows a map of the memory configuration registers and Tables 5–8 through 5–11 show the decode of the presence detect bits stored in the registers. The information in the tables is an excerpt from the JEDEC Standard Specification.

Figure 5–13 Memory Configuration Registers 0-3

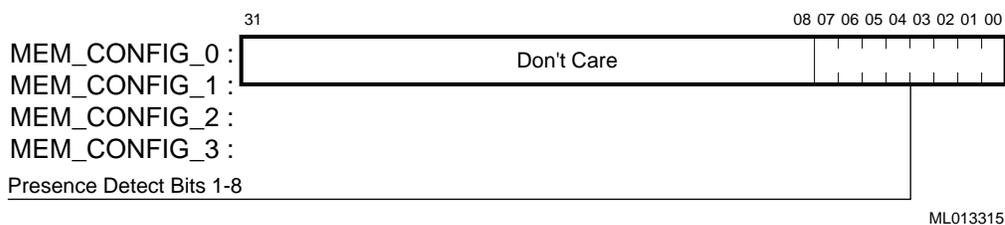

Table 5–8 Presence Detect Bits

Bit	PD Bit	Description
<3:0>	PD 4-1	See Table 5–9.
<4>	PD 5	Controls data mode access according to the values listed in Table 5–10.
<6:5>	PD 7-6	Controls speed according to the values listed in Table 5–11.
<7>	PD 8	Used to define memory DIMM configuration.

Table 5–9 Presence Detect Bits 4-1

PD Bits 4 3 2 1	Configuration (Parity/ECC)	DRAM Organization	RE Address	CE Address	Normal Refresh (ms)	Slow Refresh (ms)
0 1 0 0	1M x 72/80	1M x 4/16	10	10	16	128
0 1 0 1	2M x 72/80	1M x 4/16	10	10	16	128
1 0 1 1	4M x 72	4M x 4	12	11	64	256
1 0 1 1	4M x 80	4M x 4	12	10	64	256

Table 5–10 Presence Detect Bit 5

PD 5	Definition
0	Fast page
1	Fast page with EDO

Table 5–11 Presence Detect 7-6

Bit	ID Bit	Description
0	1	80 ns
1	0	70 ns
1	1	60 ns
0	0	50 ns
0	1	40 ns

5.4.3.5 Memory Identification Register

The memory identification register is a read-only register that stores the ID bits of the main memory DIMMs. The 21164 address and Nbus offset for the register are as follows:

21164 address	85.8001.0160
Nbus offset	80B

Table 5–12 describes the register fields.

Figure 5–14 Memory Identification Register

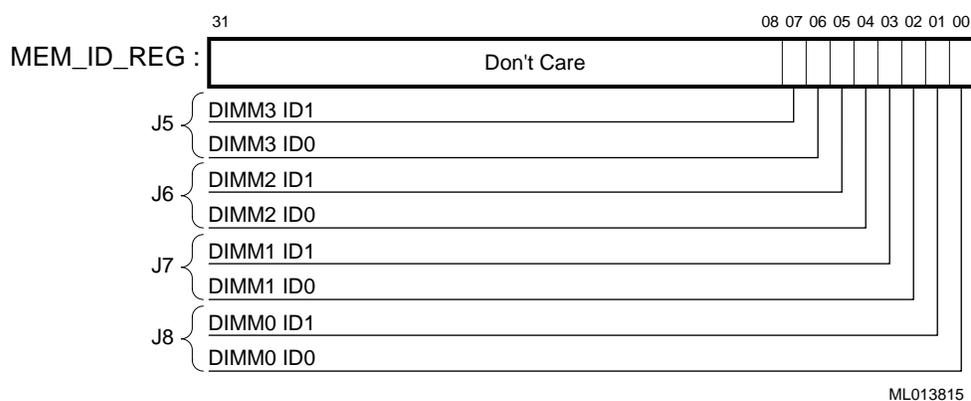

Table 5–12 Memory ID Bits

Bit	ID Bit	Description
<6,4,2,0>	ID 0	Used to define memory DIMM configuration (see the <i>DIGITAL Alpha VME 5/352 and 5/480 Single-Board Computer User Manual</i>).
<7,5,3,17>	ID 1	Sets the refresh mode according to the following values: 0 - Normal 1 - Self refresh

5.4.3.6 Heartbeat Register

The heartbeat register contains a status bit that drives the heartbeat interrupt line into interrupt register 1<5>. When the heartbeat clock is enabled in the TOY clock chip, each active (low to high, at a frequency of 1024 Hz) transition sets that status bit. Writing (data independent) to the heartbeat (clear-interrupt) register clears the heartbeat status bit and dismisses the interrupt request.

The 21164 address and Nbus offset for the heartbeat register is as follows:

21164 address	85.8001.0180
Nbus offset	80C

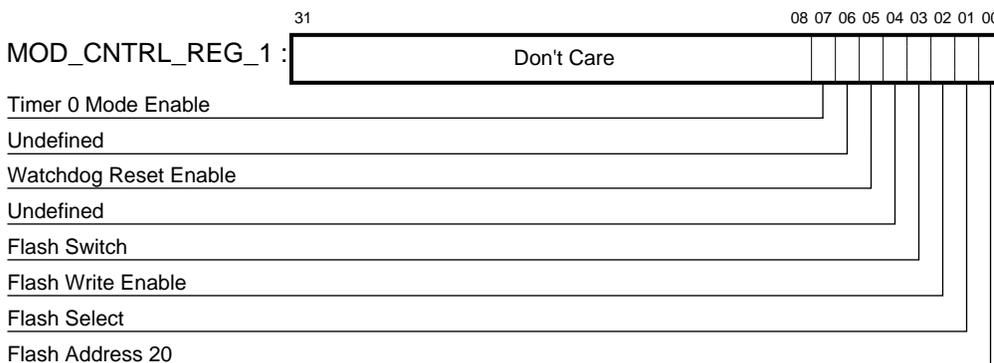

5.4.3.7 Module Control Register 1

Module control register 1 is a read/write register for controlling miscellaneous module functions. This register is reset to 0 on any system reset. The 21164 address and Nbus offset for module control register 1 is as follows:

21164 address	85.8001.01A0
Nbus offset	80D

Figure 5–15 shows module control register 1 and Table 5–13 describes the register fields.

Figure 5–15 Module Control Register 1

ML013289

Table 5–13 Module Control Register 1

Field	Name	Type	Description
<1:0>	Flash Address 20 Flash Select		Divide flash ROM into four 1 MB windows. Flash Select divides the ROM into two 2 MB segments and Flash Address 20 divides the segments in half. These two bits default to <00> at power-up, selecting the device containing the console image in the bottom 512 KB. The remaining 3.5 MB is available for user flash.
<2>	Flash Write Enable		Default at power-up is 0. When set to 1, this bit asserts write enable to the four flash ROMs to allow updates. To avoid corrupting the flash ROMs, keep this bit cleared (0) when not updating.
<3>	Flash Switch	Read only	Indicates the state of the flash ROM update DIP switch. When set, flash ROM updates are enabled. When clear, the flash Write Enable bit is not allowed to enable writes to flash.
<4>			Undefined
<5>	Watchdog Timer Reset Enable		When 0, watchdog timer expiration has no effect. If set, and the DIP bit of the reset reason register is cleared, a watchdog timer expiration generates a hardware reset of the module. Reset default is disabled.
<6>			Undefined/reserved
<7>	Timer 0 Mode 1 Enable		Default at power-up is 0. When 0, Timer 0 in the 82C54 can only operate in modes 0 and 3. When set, the polarity of the TIMERO gate input of the 8254 timer chip is inverted, allowing proper operation in modes 1 and 5.

5.4.3.8 Bcache Configuration Register

The Bcache configuration register is a read-only register that shows the size and speed of the backup cache. The CPU address and Nbus offset of this register are as follows:

21164 address	85.8001.01E0
Nbus offset	80F

Figure 5–16 shows the Bcache configuration register and Table 5–14 describes the register fields.

Figure 5–16 Bcache Configuration Register

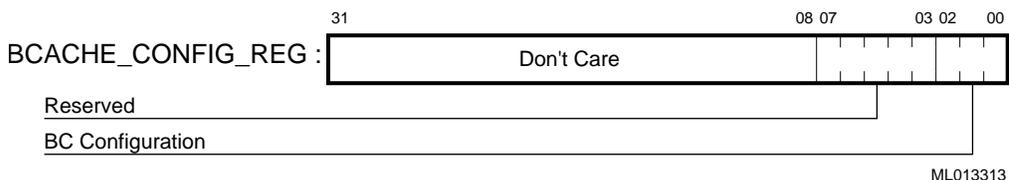

Table 5–14 Bcache Size and Speed Decode

<2>	<1>	<0>	Bcache Size	Bcache Speed
0	0	0	Disables Bcache	
0	1	0	2 MB	12 ns
0	1	1	Reserved for future use	
1	0	0	Reserved for future use	
1	0	1	Reserved for future use	
1	1	0	Reserved for future use	
1	1	1	Reserved for future use	

5.4.3.9 Reset Reason Registers

The reset reason registers record the cause of a module reset. The cause can be one of the following:

- Power-up
- VME reset
- Front panel switch
- Watchdog reset

The 21164 addresses and Nbus offsets for the reset reason registers are as follows:

Reset Reason Register	21164 Address	Nbus Offset
1	85.8001.0140	80A
2	85.8001.01C0	80E
3	85.8001.05C0	82E

These registers are read/pseudowritable registers located at a fixed address on the Nbus in PCI I/O address space. Register 1 is located at Nbus offset 0x80A but is also aliased in two longwords at 0x80E and 0x82E. The register contains four reset status bits and one diagnostics in progress (DIP) bit. In reset reason register 3, at 0x82E, any write operation sets bits <4:0>. This is for testing only.

Figure 5–17 shows the reset reason registers and Table 5–15 describes the register fields.

Figure 5–17 Reset Reason Registers

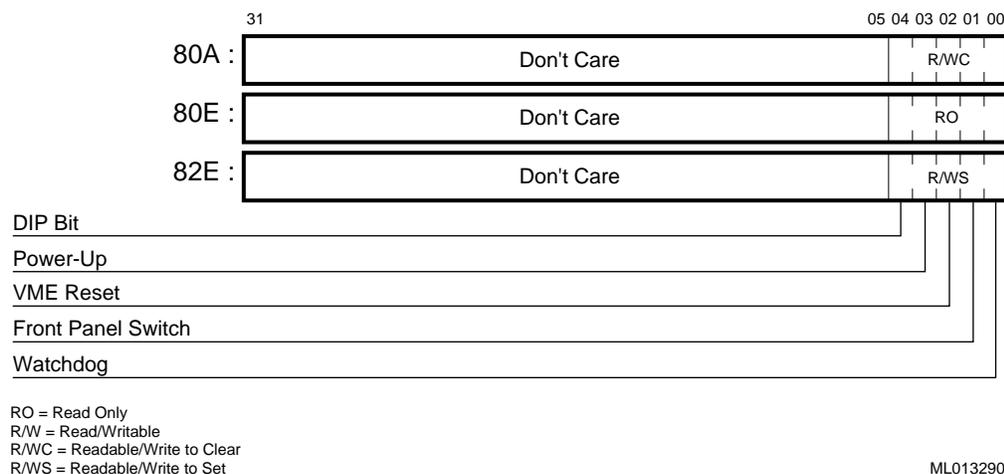

Table 5–15 Reset Reason Registers

Field	Name	Type	Description
<0>	Watchdog timer	0x80A : R/W to clear 0x80E : Read only 0x83E: R/W to set	Set immediately when a watchdog timer timeout occurs. Available to indicate the HALT reason before the system actually resets. In this case, the register forms part of the halt reason information in the system.
<1>	Front panel switch	0x80A : R/W to clear 0x80E : Read only 0x83E: R/W to set	If set, this bit indicates that the front panel switch caused a reset.
<2>	VME reset	0x80A : R/W to clear 0x80E : Read only 0x83E: R/W to set	If set, this bit indicates that the module received a VME reset.
<3>	Power-up	0x80A : R/W to clear 0x80E : Read only 0x83E: R/W to set	If set, other bits are ignored.
<4>	DIP bit	0x80A : Read only 0x80E : Read only 0x83E: R/W to set	If set, the Alpha VME 5/352 or 5/480 SBC cannot be reset.

5.4.4 Super I/O Chip Registers

The 21164 address range and Nbus offsets for the Super I/O chip (FDC37C6656T) registers are as follows:

21164 addresses	85.8000.3E00 – 85.8000.7FE0
Nbus offsets	01F0 – 03FF

Table 5–16 lists the address offsets and range of physical addresses for the Super I/O chip’s general, serial port, parallel port, and diskette controller registers. For more detail, see the *Super I/O FDC37C6656T Specification*.

Table 5–16 Super I/O Register Address Space Map

Offsets	Physical Addresses	Registers
398	85.8000.7300	General registers – index address
399	85.8000.7320	General registers – data address
	Index	Register
	0	Function enable
	1	Function address
	2	Power and test
2F8 – 2FF	85.8000.5F00 – 85.8000.5FE0	COM2 serial port registers
3F8 – 3FF	85.8000.7F00 – 85.8000.7FE0	COM1 serial port registers
3BC – 3BF	85.8000.7780 – 85.8000.77E0	Parallel port registers
1F0 – 3FF	85.8000.3E00 – 85.8000.7EE0	Diskette controller registers

The general registers are located at addresses 398 (index address) and 399 (data address). For example, writing an index value of 1 to address 398 selects the function address register. If a read transaction from address 399 follows, the data associated with the function address register is returned. If a write transaction to address 399 follows, the function address register is updated

5.4.5 TOY Clock, Watchdog Timer, and NVRAM Registers

The 21164 CPU addresses and Nbus offsets for the TOY clock, watchdog timer, and NVRAM (DS1386) are as follows:

21164 addresses	85.8010.0000 – 85.801F.FFE0
Nbus offsets	8000 – FFFF

Table 5–17 lists the address ranges for each component.

Table 5–17 TOY Clock, Watchdog Timer, and NVRAM Address Space

Component	Physical Address	Nbus Offset
TOY clock	85.8010.0000 – 85.8010.0160	8000 – 800B
Watchdog timer	85.8010.0180 – 85.8010.01A0	800C – 800D
NVRAM	85.8010.01C0 – 85.8010.01E0	800E – 800F

5.4.5.1 TOY Clock Timekeeping Registers

The TOY clock timekeeping registers keep time for the system. Time information is contained in eight 8-bit read/write registers as defined in Table 5–18.

Table 5–18 TOY Clock Timekeeping Registers

Field	Register	Physical Address	Nbus Offset
<0:3>	0.00 sec	85.8010.0000	8000
<4:7>	0.0 sec		
<0:6>	Second	85.8010.0020	8001
<0:6>	Minute	85.8010.0040	8002
<0:5>	Hour	85.8010.0080	8004
<0:3>	Day	85.8010.00C0	8006
<0:5>	Date	85.8010.0100	8008
<0:4>	Month	85.8010.0120	8009
<0:7>	Year	85.8010.0140	800A

Table 5–19 TOY Clock Command Register

Field	Name	Type	Description
<5>	Watchdog Timer Assertion	R/W	
<6>	Watchdog Timer Select	R/W	
<7>	Transfer Enable	R/W	Enables/disables changes to the values in the timekeeping registers. When clear, the current value in the readable registers is frozen even though the internal timing continues. This prevents the update of the registers from changing the values during a read operation or from updating the new value during a write operation.

The 1024 Hz square wave clock output of the TOY clock is fed to interrupt register 2<5>. Every time the clock makes a low-to-high transition, the interrupt register 2<5> is asserted and held asserted. The interrupt request input is only deasserted by writing to the heartbeat (clear-interrupt) register at address 0x80C on the Nbus.

5.4.5.3 Watchdog Timer Registers

Watchdog timer operation is controlled by four registers - three in the DS1386 chip and a single enable bit in the module control register. Operation of the watchdog timer must be configured in the TOY clock command register and enabled in the module control register (MOD_CNTRL_REG).

Sections 5.4.5.4 to 5.4.5.6 describe the following watchdog timer registers and register fields:

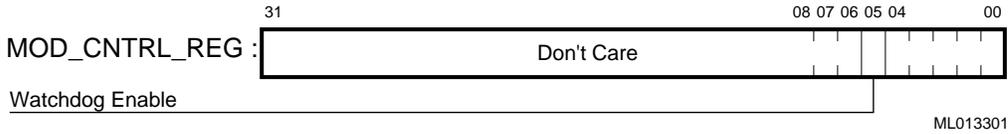

- Watchdog timer field in the module control register, Section 5.4.5.4
- Watchdog timer fields in the TOY clock command register, Section 5.4.5.5
- Watchdog timer registers, Section 5.4.5.6

5.4.5.4 Watchdog Timer Field in the Module Control Register

The possibility exists for setting up the watchdog timer in such a way that it would constantly drive the module into reset. For example, this can be done by setting the watchdog timer output to level rather than pulse. To address this, the Alpha VME 5/352 and 5/480 SBCs define an external watchdog enable bit in the module control register, which defaults to disabled when a system is powered on. When the watchdog timer has been fully and correctly initialized, this bit should be set to allow normal watchdog timer operation.

Figure 5–19 identifies the watchdog enable bit in the module control register. For a more complete description of the module control register, see Section 5.4.3.7.

Figure 5–19 Watchdog Timer Field in the Module Control Register

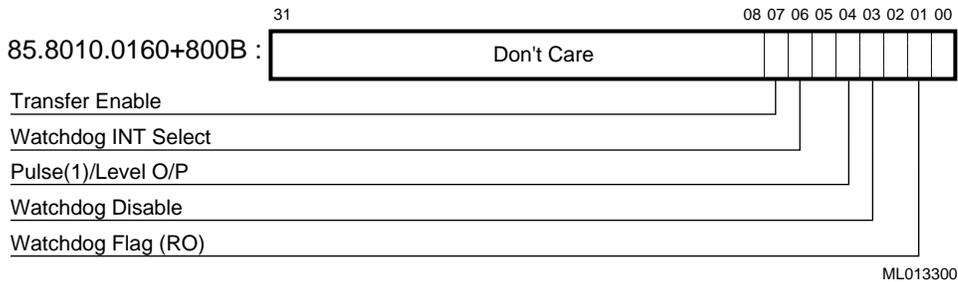

The reset generated by the watchdog timer is “one-shot,” because the module control register is cleared, disabling the watchdog timer reset when the hardware reset is asserted.

5.4.5.5 Watchdog Timer Fields in the TOY Clock Command Register

Within the TOY clock chip, the interrupt line and the pulse/level assertion of that interrupt line for the watchdog timer are selectable in the TOY clock command register. In addition, the watchdog function can be enabled or disabled by the TOY clock command byte, bit <4>. Figure 5–20 shows the required setup of the watchdog timer in the TOY clock command register, which is located at 21164 physical address 0x85.8010.0160/Nbus offset 0x800B.

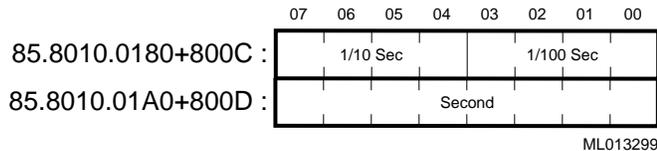

Figure 5–20 Watchdog Timer Fields in the TOY Clock Command Register

5.4.5.6 Watchdog Timer Registers

The watchdog timer timeout value is set in BCD in two byte-wide watchdog timer registers in the TOY clock’s address space, as Figure 5–21 shows. The registers are located at 21164 physical address 0x85.8010.0180/Nbus offset 0x800C and 21164 physical address 0x85.8010.01A0/Nbus offset 0x800D.

Figure 5–21 Watchdog Timer Registers

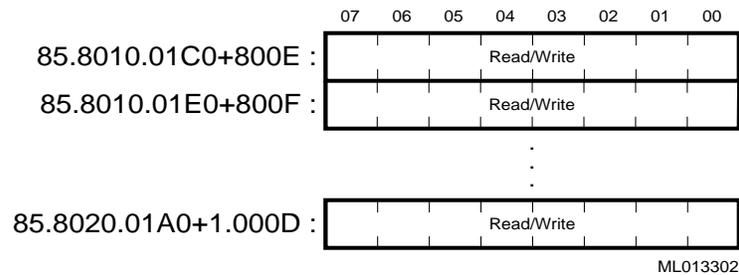

5.4.5.7 Nonvolatile RAM

Alpha VME 5/352 and 5/480 SBCs offer just under 32 KB of battery backed-up on-board SRAM. The RAM is provided by the DS1386 chip and is held nonvolatile by the built-in lithium battery source.

The memory is read/write accessible in Nbus space. In effect, the DS1386 chip (TOY clock, watchdog timer, and NVRAM) contains 32 KB read/write byte elements. The lowest 14 of these bytes have special register functions for operation of the TOY clock and watchdog timer. The remaining bytes, 32 KB-14, are usable as general-purpose bitwise read/write RAM.

This RAM is organized as contiguous bytes ranging from 21164 physical address 85.8010.01C0/Nbus offset 0x800E through 21164 physical address 85.8020.01A0/Nbus offset 0x1000D, as shown in Figure 5–22.

Figure 5–22 NVRAM Access

As for the TOY clock operation, module switch 1 allows the VMEbus 5VSTDBY to be connected to the DS1386 giving RAM backup that is independent of both the normal 5 V supply and the internal lithium battery.

The firmware uses NVRAM for module parameters and settings, and error and failure information.

The lowest 16 KB of the battery backed-up RAM is reserved for firmware usage. Thus, user and O/S code should not access NVRAM below Nbus offset C000 physical address 85.8018.0000.

5.4.6 Interval Timer Registers

The 21164 addresses and Nbus offsets for the interval timer (82378ZB) are as follows:

21164 addresses	87.8008.0000 – 85.800B.FFE0
Nbus offsets	4000 – 7FFF

The interval timer address space spans from 0x8580080000 to 0x85800BFFE0, taking up the least significant byte of six adjacent longwords in Nbus space. The first four are the standard four bytewise registers of the 82C54 chip, and the other two bytes are an interrupt status register.

Sections 5.4.6.1 to 5.4.6.5 describe the following:

- Timer registers, Section 5.4.6.1
- Timer modes, Section 5.4.6.2
- Timer interface registers, Section 5.4.6.3
- Interval timing control/status register, Section 5.4.6.4
- Timer interrupt status register, Section 5.4.6.5

5.4.6.1 Timer Registers

The 82C54 chip is made up of three independent 16-bit counter/timers that are functionally identical. Table 5–20 describes each timer.

Table 5–20 Timers

Timer	Description
Timer 0	Must be clocked externally by P2 pin C13. Optionally, this timer's gate input can be driven by P2 pin C14. When this timer makes a low-to-high transition, its output causes the assertion of an input request (IRQ). To dismiss the IRQ, you need to access the timer interrupt status register.
Timer 1	Operates as a rate generator with its output being driven off-module by P2 pin C12. This timer is clocked by a fixed 10 MHz. The output is also routed directly to the VIC local IRQ input <3>.
Timer 2	Operates as a rate generator with its output connected to P2 pin C11. This timer is clocked with the same fixed 10 MHz. You can also use the output on the module to generate an IRQ. If enabled, Timer #0's output during a transition from low-to-high causes the assertion of an IRQ. To dismiss the IRQ, you need to access the timer interrupt status register.

The timers are implemented by register/interrupt logic. The programming interface is byte wide in the Nbus region of PCI I/O space.

5.4.6.2 Timer Modes

In addition to supporting the three timers discussed in Section 5.4.6.1, the Alpha VME 5/352 and 5/480 SBCs implement two timer modes (modes 1 and 3) provided by the 82C54 chip for timers 1 and 2. The hardware connections for the timer output are available on the P2 VMEbus connector. The timers are driven from an internally generated 10 MHz asynchronous clock.

Table 5–21 Timer Modes

Mode	Description
1	Allows the application to write a value n to the timer. An external hardware trigger causes the timer to count down from n to zero. If a new value n is written to an associated mode 1 register before the countdown reaches zero, the timer begins counting from the new value at clock $n+1$.
3	Allows the application to write a value n to the timer. The timer uses the value to generate a square wave with a period equal to n times the 10 MHz clock period.

You can use these timers for a variety of off-module functions.

5.4.6.3 Timer Interface Registers

The timer interface registers take up the least significant byte of six adjacent long-words in Nbus space (see Table 5–22). The first four are the standard four byte-wide registers of the 82C54 chip, and the other two bytes are an interrupt status register.

Table 5–22 Timer Interface Registers

Field	Register	Physical Address	Nbus Offset
<7:0>	Timer 0 Data Register	85.8088.0000	4000
	Timer 1 Data Register	85.8088.0080	4004
	Timer 2 Data Register	85.8088.0100	4008
	Control/Status Register	85.8088.0180	400C
	Interrupt Status Register	85.8088.0200	4010
	Interrupt Status Register	85.8088.0280	4014

To program the timer device for initialization or during normal operation, write to the Control/Status Register. To access (read or write) the individual timer count values, use the separate timer data registers.

5.4.6.4 Interval Timing Control/Status Register

The interval timing (82C54) control/status register contains the control byte that defines the mode of operation (continuous or single-shot) for and provides access control to each individual timer. Figure 5–23 shows the interval timing control/status register, which is located at 21164 physical address 0x85.8088.0180/Nbus offset 0x400C. Table 5–23 describes the fields of the interval timing control/status register.

Because only a single byte in the 82C54 address space is used to access the full 16-bit counter value, two accesses are required to operate on the full 16 bits. The access can use least-significant bit, most-significant bit, or both.

Figure 5–23 82C54 Control/Status Register

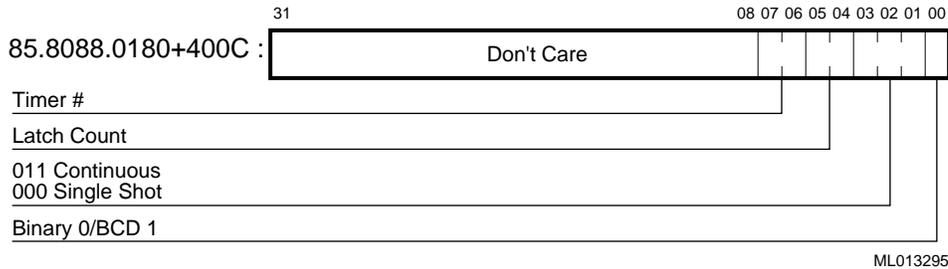

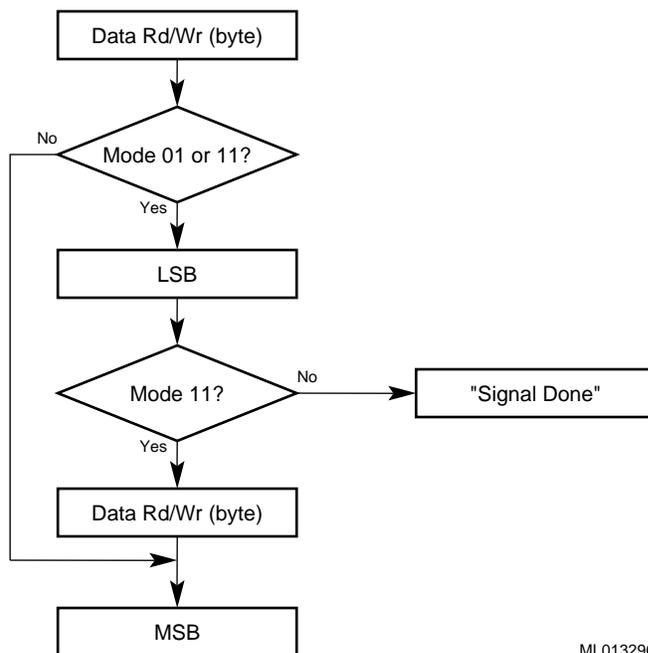

Table 5–23 Interval Timing Control/Status Register

Field	Description
<7:6>	Specifies which timer is to be configured by this control byte. When set to “11”, the control byte is a status read command, not a Timer Control operation. As a status read command, the control byte can be used to freeze the state of the timers for read-back. Information pertaining to the assertion state of the output pin, the mode of operation, the read-write access mode, and so forth, is then available by reading the timer data register.
<5:4>	Sets the data interface to accept one or both of the bytes of the timer’s 16-bit counter whenever a read or a write operation to that timer occurs. When set, all operations to the timer register are in the format set until a new mode is set by another control byte to the timer, according to the following values: 00 – Latch count for read-back 01 – Least significant bit (LSB) access mode 10 – Most significant bit (MSB) access mode 11 – LSB, MSB access mode
<3:1>	Defines the operational mode of the timer, according to the following values: 011 – Continuous 000 – Single shot
<0>	Sets the timer’s 16-bit counter to either binary or binary coded decimal (BCD). When clear, the format is binary. When set, the format is BCD.

Figure 5–24 shows a conceptual view of the operation of the timer byte-wide data interface. The “signal done” action is important where the completion of a data access becomes an implicit **start/go** command to the timer.

Figure 5–24 82C54 Timer Data Access

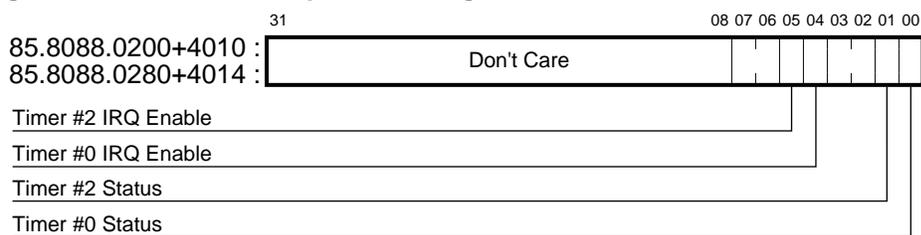

ML013296

5.4.6.5 Timer Interrupt Status Register

The timer interrupt status register is aliased as the bottom byte in two contiguous longwords (as shown in Table 5–22). The action of the register is slightly different, depending on the address at which it is accessed and whether the access is a read or a write. Figure 5–25 shows the timer interrupt status register, which is located at 21164 physical address 0x85.8088.0200/Nbus offset 0x4010 and 21164 physical address 0x85.8088.0280/Nbus offset 0x4014.

Figure 5–25 Timer Interrupt Status Register

ML013298

5.4.7 Keyboard and Mouse Controller Registers

The 21164 CPU addresses and Nbus offsets for the keyboard and mouse controller (82C42PE) are as follows:

21164 addresses	85.8000.0C00 – 85.8000.0C80
Nbus offsets	0060 – 0064

Table 5–24 lists the offsets and physical addresses for the keyboard and mouse controller registers.

Table 5–24 Keyboard and Mouse Controller Addresses

Offsets	Physical Address	Register
60-R	85.8000.0C00	Auxiliary/keyboard
60-W	85.8000.0C00	Command data
64-R	85.8000.0C80	Read status
64-W	85.8000.0C80	Command

5.5 Summary of VME Interface Registers

A summary of VME interface registers is shown in Table 5–25.

Table 5–25 VME_IF_BASE +

Offset	Register	Description
00	VIC_IICR	VMEbus interrupter interrupt control register
04-1C	VIC_ICPR1-7	VMEbus interrupt control registers 1-7
20	VIC_DMASICR	DMA status register
24-3C	VIC_LICR1-7	Local interrupt status register
40	VIC_ICGISR	ICGS interrupt control register
44	VIC_ICMSICR	ICMS interrupt control register
48	VIC_EGICR	Error group interrupt control register
4C	VIC_ICGSIVBR	ICGS vector base register
50	VIC_ICMSVBR	ICMS vector base register
54	VIC_LIVBR	Local interrupt vector base register
58	VIC_EGIVBR	Error group interrupt vector base register
5C	VIC_ICSR	Interprocessor communications switch register
60-70	VIC_ICR0-4	Interprocessor communications registers 0-4
74	VIC_ICR5	Interprocessor communications register 5
78	VIC_ICR6	Interprocessor communications register 6
7C	VIC_ICR7	Interprocessor communications register 7
80	VIC_VIRSR	VMEbus interrupt request/status register
84-9C	VIC_VIVBR1-7	VMEbus interrupt vector base registers 1-7
A0	VIC_TTR	Transfer timeout register
A4	VIC_LBTR	Local bus timing register
A8	VIC_BTDR	Block transfer definition register
AC	VIC_ICR	Interface configuration register
B0	VIC_ARCR	Arbiter/requester configuration register

Table 5–25 VME_IF_BASE + (Continued)

Offset	Register	Description
B4	VIC_AMSR	Address modifier source register
B8	VIC_BESR	Bus error status register
BC	VIC_DMASR	DMA status register
C0	VIC_SS0CR0	Slave select 0/control register 0. The D32 enable must be set in VIC_SS0CR0.
C4	VIC_SS0CR1	Slave select 0/control register 1
C8	VIC_SS1CR0	Slave select 1/control register 0
CC	VIC_SS1CR1	Slave select 1/control register 1
D0	VIC_RCR	Release control register
D4	VIC_BTCR	Release control register
D8	VIC_BTLR1	Block transfer length register 1
DC	VIC_BTLR0	Block transfer length register 0
E0	VIC_SRR	System reset register
E4	BTLR2	Block transfer length register 0
E8-FC		Reserved locations
100	VIP_CR	VME interface processor control register
104	VIP_BESR	VME interface processor bus error/status register
108	VIP_ICR	VME interface processor interrupt control register
10C	VIP_IRR	VME interface processor interrupt control register
110	VIP_HWIPL	VME interface processor hardware IPL mask register
114	VIP_DIAG_CSR	VME interface processor diagnostic register
118	VIP_PMCSR	VME interface processor page monitor CSR
11C	VIP_OBISGABR	VME interface processor outbound internal scatter-gather entry ABR
120	VIP_OBISGMSK	VME interface processor outbound internal scatter-gather entry mask
124	VIP_OBISGWORD	VME interface processor outbound internal scatter-gather entry control word
128	VIP_IBISGMSK	VME interface processor inbound internal scatter-gather entry mask
12C	VIP_IBISGWORD	VME interface processor inbound internal scatter-gather entry control word
130	VIP_SGCCHIX	VME interface processor scatter-gather cached index
134	VIP_SGCWRD	VME interface processor scatter-gather cached control word

Table 5–25 VME_IF_BASE + (Continued)

Offset	Register	Description
138	VIP_PCIERTADR	VME interface processor PCI error target address register
13C	VIP_PCIERTCBE	VME interface processor PCI error target command/byte enables register
140	VIP_PCIERIADR	VME interface processor PCI error initiator address register
144	VIP_LERADR	VME interface processor VME/local bus error address register
148-17C		Reserved locations
180	VIFMASK	VMEbus i/f address base mask register
184	VIFABR	VMEbus i/f address base register
188-3FC		Reserved

T

- Time, setting, 5-26
- Timekeeping registers, 5-26
 - freezing, 5-28
- Timeout
 - Fairness Request scheme, 3-20
 - for local bus, 3-14
 - for VMEbus, 3-14
 - interrupt mask for arbitration, 3-13
 - VMEbus arbitration, 3-14
 - watchdog timer, setting, 5-29
- Timeout timers, 3-19
 - controlling, 3-20
- Timer
 - count values, 5-32
 - interface registers, 5-32
 - interrupt status register, 5-34
 - modes, 5-32
 - enabling, 5-22
 - programming, 5-32
- Timer 0 register, 5-32
- Timer 1 register, 5-32
- Timer 2 register, 5-32
- Timer modes
 - enabling, 5-22
- Timers, 5-31
 - controlling, 3-20
 - data access of, 5-34
 - interval
 - defining the operational mode of, 5-33
 - freezing the state of, 5-33
 - setting acceptance of the bit counter for, 5-33
 - setting the counter of, 5-33
 - local bus transfer, 3-21

- timeout, 3-19
- VMEbus arbitration, 3-20
- VMEbus transfer, 3-21
- Timing, local bus, 3-15
- TOY clock, 1-2, 1-10, 5-21
 - command register, 5-27
 - watchdog timer fields in, 5-29
 - oscillator
 - disabling, 5-27
 - oscillator disabling, 5-27
 - timekeeping registers, 5-26, 5-28
- Transfer mode, accelerated, 3-15
- Transfer timeout register (TTR), 3-14, 3-21
- Transfer timers
 - local bus, 3-20
 - VMEbus, 3-20
- Transmit poll demand register, 5-3
- TTR (VME transfer timeout register), 3-14, 3-21
- Turbo mode, 3-14
- Tx list base address register, 5-3

V

- Valid bit of scatter-gather entries, 3-5
- VIC chip
 - registers for, 3-12
- VIC_EGICR (VME error group interrupt register), 4-5
- VIC64 chip
 - interrupt ranking, 4-4
 - system interrupt controller, 1-9
- VIC64 chip registers, 3-11
- VICR (VME interrupt control register), 3-12
- VICR1-7 (VME interrupt control registers 1-7), 3-12
- VIP chip, 1-12, 1-13
 - interrupt sources, 4-5
- VIP location monitor status, 4-1
- VIRSR (VME interrupt request/status register), 3-14
- VIVBR1-7 (VME interrupt vector base registers 1-7), 3-14
- VME address mapping, 2-8
- VME address modifier status register (AMSR), 3-14, 3-15
- VME address space, 3-2
 - getting access to, 3-11
- VME address spaces, 2-8
- VME address windows, 2-8, 3-2
- VME address space
 - map from PCI address space, 3-3
- VME arbiter/requester register (ABR), 3-19
- VME block transfer control register (BTCR), 3-15, 3-17
- VME block transfer definition register (BTDR), 3-14, 3-17
- VME block transfer length register 0 (BTLR0), 3-16
- VME block transfer length register 1 (BTLR1), 3-16
- VME block transfer length registers 1-0 (BTLR1-0), 3-15
- VME bus error/status register (BESR), 3-5, 3-15, 3-21
- VME chip, 1-12, 1-13
 - address map for, 3-12
 - byte swap modes for, 3-23
 - configuring, 3-12
 - resetting of, 5-14
 - revision of, 3-13
 - system interrupt controller, 4-4
 - interrupt sources of, 4-5
 - system interrupt controller for, 4-1
 - write post failure, 4-5
- VME control/status register base (VME_CSR_BASE), 3-10
- VME DMA interrupt control register (DMAICR), 3-17
- VME DMA status interrupt control register (DMASICR), 3-12, 4-6
- VME DMA status register (DMASR), 3-15
- VME error group interrupt control register (EGICR), 3-13, 3-21, 4-5
- VME error group interrupt vector base register (EGIVBR), 3-13, 3-17, 4-6
- VME interface, 1-12, 3-1
 - addresses, decoding, 3-7
 - initialization, 3-10
 - configuring PCI interface for, 3-10
 - configuring VIC64 chip for, 3-12
 - programming scatter-gather RAM for, 3-11
 - interprocessor communication
 - global switches, 3-18
 - module switches for, 3-19
 - registers for, 3-18
 - interrupts generated by, 4-1
 - resetting, 3-19
 - scatter-gather mapping, outbound, 3-4
 - services supported by, 3-1

- VME interface configuration register (ICR), 3-6
- VME interprocessor communication
 - function status register (ICFSR), 3-13
 - global switch interface
 - configuration register (ICGSICR), 3-13
 - vector base register (ICGSIVBR), 3-13, 3-18
 - group processor register (ICGPR), 3-18
 - module switch interface
 - configuration register (ICMSICR), 3-13, 3-19
 - vector base register (ICMSIVBR), 3-13
 - module switch interface vector base register (ICMSIVBR), 3-19
- VME interrupt control register (ICR), 3-5, 3-14
- VME interrupt control register (VICR), 3-12
- VME interrupt control register 5 (ICR5), 3-13
- VME interrupt control register 6 (ICR6), 3-13
- VME interrupt control register 7 (ICR7), 3-13
- VME interrupt control registers 0-4 (ICR0-4), 3-13
- VME interrupt control registers 1-7 (VICR1-7), 3-12
- VME interrupt request/status register (VIRSR), 3-14
- VME interrupt vector base registers 1-7 (VIVBR1-7), 3-14
- VME interrupter, 3-14
- VME interrupter interrupt control register (IICR), 4-6
- VME local bus timeout register (LBTR), 3-14
- VME local interrupt control registers 1-7 (LICR1-7), 3-12
- VME local interrupt vector base register (LIVBR), 3-13
- VME release control register (RCR), 3-15, 3-18, 3-20
- VME reset, 5-24
- VME scatter-gather base (VME_SG_BASE) register, 3-10
- VME slave selection 0 control
 - register 0 (SS0CR0), 3-15
 - register 1 (SS0CR1), 3-15
- VME slave selection 1 control
 - register 0 (SS1CR0), 3-15
 - register 1 (SS1CR1), 3-15
- VME system reset register (SRR), 3-15
- VME transfer timeout register (TTR), 3-14, 3-21
- VME window 1 base
 - (VME_WINDOW_1_BASE) register, 3-10
- VME window 2 base
 - (VME_WINDOW_2_BASE) register, 3-10
- VME_CSR_BASE (VME control/status register base), 3-10
- VME_SG_BASE register, 3-10
- VME_WINDOW_1, 3-2
- VME_WINDOW_1 address window, 2-8
- VME_WINDOW_1_BASE register, 3-10
- VME_WINDOW_2, 3-2
- VME_WINDOW_2 address window, 2-8
- VME_WINDOW_2_BASE register, 3-10
- VMEbus, 3-20
 - acquisition time, 3-14
 - address mapping, 1-14, 3-2
 - addressing modes, 1-12
 - arbitration
 - controlling, 3-19
 - programming delays of, 3-17
 - timeout timers for, 3-19
 - arbitration mode, 3-15
 - arbitration timeout, 4-5
 - arbitration timers, 3-20
 - as interrupt servicing agent, 3-21
 - as interrupter, 3-21
 - as system controller, 3-14, 3-19
 - block mode data transfers on, 3-16
 - setting up for, 3-16
 - byte lane formats for, 3-24
 - data transfer timers for, 3-20
 - data transfers, 1-12
 - DMA block mode data transfers on, 3-16
 - fairness timer enable, 3-14, 3-15
 - granting ownership of, 3-19
 - IACK cycle, 4-5
 - interrupt control, 3-19
 - interrupt handling for, 3-21
 - interrupts, 4-5
 - mapping memory pages to PCI bus, 3-7
 - master, 3-1
 - Fair Request scheme for, 3-20
 - transactions, 3-4
 - modules
 - interrupting, 3-18
 - protocols, 1-12
 - read-modify-write cycles, atomic, 3-5
 - release mode, 3-15
 - release modes for, 3-20
 - releasing, 3-20

- request level, 3-15
- requesting, 3-19
- reset
 - interruts generated by, 4-1
 - scatter-gather map, 1-14
 - single mode data transfers on, 3-16
 - slave, 3-1
 - slave access, programming, 3-17
 - system controller, 3-1
 - transfer timers for, 3-21
- Voltage supply
 - PMC I/O companion card, 1-8

W

- Watchdog timer, 1-2, 1-11
 - as a reset reason, 5-24
 - assertion, 5-28
 - enabling, 5-27, 5-28
 - fields in TOY clock, 5-29
 - flag for, 5-27
 - registers, 5-28, 5-29
 - reset enable, 5-22
 - setting timeout for, 5-29
 - TOY clock command register, 5-29
- Watchdog, arbitration, 3-20
- Windows, VME address, 2-8, 3-2
- Word swap mode, 3-22
- Write buffers, 2-6, 2-7
- Write operations, deferring, 3-16
- Write post failure, 4-5
- Write transactions, 2-6

X

- Xilinx interrupt controller, 1-9, 4-1, 4-3, 5-17
