INTERACTIVE UNIX* Operating System Primer

INTRODUCTION

What Will I Learn From This Primer?

This primer is an introduction to the basic components and features of the INTERACTIVE UNIX System V/386 Release 3.2 Operating System, Version 3.0 It was written to provide you with the information you need to start using the system. It is not intended as a technical reference manual. If you require detailed documentation, refer to the "Documentation Roadmap" in the INTERACTIVE UNIX System V/386 Release 3.2 Operating System Guide.

In this primer you will learn how to:

- Execute and stop INTERACTIVE UNIX Operating System commands.
- Interpret INTERACTIVE UNIX System error messages.
- Create directories to organize documents such as memoranda, letters, reports, and tables.
- Use the INTERACTIVE UNIX System command interpreter, the shell.

To reinforce what you read in this primer, try each example on your system.

New terms introduced in italics can be found in the glossary at the end of this primer.

Documentation References

Throughout this guide, the following full documentation titles will be referenced in shortened versions as follows:

GETTING STARTED

Before you can begin this section, you or your system administrator must install your system and set up your *login account*. If the power to your computer is off, you must *boot* (bring up) the system before you can *log in*.

Booting the System

Before you can log in to your computer, you must boot the *operating system*. The operating system is the group of programs and utilities that manages the computer's resources, processes user requests, and runs application programs. You must boot the system at the *console*, or main, terminal, which is the terminal directly attached to the computer unit. Use this procedure:

- 1. Make sure that there is no diskette in the disk drive.
- 2. If you have turned off your computer, turn it on again. The INTERACTIVE UNIX Operating System is automatically booted from the fixed disk.
- 3. If the power to your computer is turned on and your system has been previously shut down (refer to the section "Shutting Down the System" in this primer), press any key to reboot your system.
- 4. Booting the UNIX System... appears on your screen and the computer begins to boot. The screen then clears and a number of messages appear. The system is ready for you to log in when you see the message Console Login:.

Logging In

To use the INTERACTIVE UNIX System, you must turn on your computer or terminal and log in. If you are logging in to the console terminal, your screen will look like this:

Console Login:

If you are using a terminal other than the console terminal, your screen will look like this:

login:

Type the user identification name (ID) assigned to you (this is also called your login), then press **ENTER**. Your user ID can contain a maximum of eight characters and can consist of uppercase letters, lowercase letters, and numerals. By convention, most user IDs on UNIX Systems consist of lowercase letters.

After a user ID is entered, the system may request a password:

```
login: tony
Password:
```

If you have been assigned a password by your system administrator, when Password: displays, type your password and press **ENTER**.

The system does not display the password you type on the screen.

If you have not been assigned a password, your screen will look similar to this:

```
login: tony
*** Welcome to the UNIX Operating System. ***
$
```

If you accidentally log in using uppercase letters, the system assumes that your terminal (console included) is not capable of handling lowercase letters. All input and output for the remainder of the session will be shown in uppercase letters. If this happens, log off, make sure your **CAPS-LOCK** key is not engaged, and log in again.

When you have completed the login procedure, the system displays a *prompt* on the screen. The prompt is a symbol, usually a dollar sign (\$) or a percent sign (%), but because this character can be changed by your system administrator, your prompt may be different. The prompt indicates that the system is ready to receive information. You may enter a command or run an application when the prompt is displayed on your screen.

When you interact with the operating system, the commands you type are processed by a *command interpreter*, which passes your commands to the operating system for processing and delivers the results to you. The INTERACTIVE UNIX System command interpreter is called the *shell*, and the prompt that is displayed is usually called the *shell prompt*. You will learn more about the shell in the section "USING THE SHELL" in this primer.

Your Home Directory

Each time you log in, the system places you in your home directory. Your home directory serves as your personal work area.

A directory file (such as your home directory) can contain both files and other directories. It is similar in function to a file cabinet: a file cabinet has several drawers (directories), each of which can contain many folders (subdirectories), each holding one or more documents (files). A file is a collection of data stored under an assigned name. For example, a letter, a sales report, or payroll data can all be stored in files. You will learn more about directories and files in the section "INTERACTIVE UNIX SYSTEM DIRECTORY STRUC-TURE" in this primer.

Setting a Password (passwd)

If you were not assigned a password when your login account was set up, the system will probably request that you choose one the first time you log in. A password keeps unauthorized users from tampering with your files by assuring that no one can log in to your account on the computer. Once your password is set, only you, or someone who knows your password, can access your account.

COMMAND NAME	passwd
FORMAT	passwd
DESCRIPTION	Set or change your login password. The program prompts for the old password (if any) and prompts twice for the new password.
OPTIONS	None.
ARGUMENTS	None.

Log in to the system. The system prompts you immediately for a password:

login: tony \$ New password:

Enter a word between six and eight characters long that will be easy for you to remember, then press **ENTER**. The password must contain at least one numeric or special character. Special characters include the space character and:

< > * ? | & \$; \ " ` ` ` () []

Note that when you type in the word you have chosen, the system does not display it on the screen. The system verifies the password by asking you to type it again:

> New password: Re-enter new password:

If you make a mistake entering your password the second time, the system will give you another chance.

Some system administrators assign all new users a default password when their login accounts are established. You should change this as soon as you log in so that others who may know the default password do not have access to your account. Use the passwd command to change your current password. Type the passwd command at the shell prompt, then press **ENTER**:

\$ passwd

Remember to type the command exactly as it is shown in the example. You may not type password or any other variation of the command.

The system asks you to type in your old password, prompts you for a new one, and then has you verify the new one by typing it a second time:

```
$ passwd
passwd: Changing password for tony
Old password:
New password:
Re-enter new password:
```

Don't forget your password! You need it to log in to the system.

6

Logging Out

To end your access to the system, you must *log out*. Always log out when you have finished using the computer, to prevent unauthorized use of your account.

On most systems there are two ways you can log out. You can hold down the \boxed{CTRL} key and simultaneously press \boxed{d} , or you may type the exit command at the prompt:

\$ exit

It is not necessary to press **ENTER** after logging out. The computer will display the login: prompt, indicating that it is ready to accept a login name for the next session.

Shutting Down the System

The INTERACTIVE UNIX Operating System is a *multi-tasking* system. A multi-tasking system means that the computer can be running many different processes (programs) at the same time. For example, you may be editing a file at the same time another file is being printed on your printer. When you are ready to turn off your computer, you must arrange for the computer to complete all of the tasks that are currently running. This is accomplished by logging in with a special administrative login account called powerdown, which runs a system maintenance procedure called shutdown. The shutdown program will gracefully terminate the tasks that are currently executing before halting the system. When shutdown has finished, you can safely turn off the computer.

If you do not run the shutdown program, you may lose data that is stored on your system and cause damage to your file system.

When you are ready to turn your machine off, you may bring the system down with a special administrative login account called powerdown, which safely runs the shutdown procedure. You must be authorized to use this login account. Follow this procedure:

- 1. Log out of your ordinary user account.
- 2. Log in to the system with the powerdown user ID.
 - Note that you must know the powerdown password if one has been set (see your system administrator).

3. Once you have completed the login procedure using the powerdown login, the system automatically executes the shutdown program. The system displays a screen similar to this:

```
login: powerdown
Password:
UNIX System V Release 3.2 80386
Copyright (c) 1989 AT&T
All rights reserved
Once started, a powerdown CANNOT BE STOPPED.
Do you want to start an express powerdown [y, n, ?, q]
```

4. If you are ready to bring the system down, type y. The system responds:

Shutdown started Wed Jun 3 17:31:44 PDT 1987 Broadcast message from root (console) on plato Wed Jun 3 17:31:44 PDT 1987 THIS SYSTEM IS BEING SHUTDOWN !!! Log off now or risk your files being damaged.

INIT: New run level 0 The system is coming down, please wait. System services are now being stopped. Stopping process accounting.

The system is down Press any key to re-boot.

5. When the Press any key to re-boot message appears, the computer may be turned OFF.

USING UNIX SYSTEM COMMANDS

On INTERACTIVE UNIX Operating Systems the words *command* and *program* are nearly synonymous. In simple terms, the user types a command, followed by **ENTER**, and the INTERACTIVE UNIX System runs the program that performs the user's command.

An INTERACTIVE UNIX System command line can have three parts: the command name, its options, and its arguments. Each command line is entered in to the computer by pressing $\boxed{\text{ENTER}}$. When the $\boxed{\text{ENTER}}$ is received, the shell sends the command to the operating system for execution.

To stop the execution of a command, press **DEL**.

Command Syntax

The INTERACTIVE UNIX System is case sensitive, which means that the system always distinguishes between uppercase and lowercase letters. Most INTERACTIVE UNIX System commands, options, and arguments are typed in lowercase letters. Options typically begin with a dash (-). Each command, option, or argument consists of one *word*, which is interpreted as a group, or *string*, of characters surrounded by spaces.

If you make an error when typing a command, use the **BACKSPACE** key to correct the error. You may *not* use the *cursor* positioning (arrow \rightarrow) keys.

Always type the command name first, followed by a space; the desired option or options, each followed by a space; then any arguments, separated by spaces.

Here is the command format:

COMMAND NAME	command name
FORMAT	<pre>command [option(s)] argument(s)</pre>
DESCRIPTION	A brief description of what the command does.
OPTIONS	A list of the most useful options and a brief description of each.
ARGUMENTS	Mandatory or optional arguments.

If an argument is not required, it is shown in square brackets []. Options are always "optional," so they are always shown in square brackets []. Only the most common options and arguments are discussed in this primer. If there are additional options or arguments available for a particular command that are not presented in this primer, this is indicated by the phrase "Not presented in this document." For a complete listing of the available options and arguments for a command, refer to the reference manuals for your system.

Command Names

INTERACTIVE UNIX System command names are short or abbreviated words that describe the programs they invoke. They are deliberately kept short to save time and reduce typing errors. The passwd command is an example of an abbreviated word used as a command name. When you enter an INTERACTIVE UNIX System command name, you *cannot* abbreviate it or change its spelling in any way.

For the novice user, INTERACTIVE UNIX System command names can be cryptic and confusing. Because the UNIX System was originally developed for systems programmers, many of the commands were not created with the new user in mind. However, you need only learn a few commands to run application programs and other facilities on your system. If your system includes a user-friendly interface such as the TEN/PLUS* interface, you will not have to learn many UNIX System commands at all.

Using a Simple Command

You have already used the passwd command to set or change your system password. passwd is an example of a simple command that requires only the command name to execute properly.

The 1s command can also be executed using only the command name. 1s is used to "list" the names of the files and directories in the current directory. (You will learn more about files and directories in the section "INTERACTIVE UNIX SYSTEM DIRECTORY STRUCTURE.")

COMMAND NAME	ls
FORMAT	<pre>ls [file name(s)] ls [directory name(s)]</pre>
DESCRIPTION	For each directory named, alphabetically list its contents. For each file named, list the requested information.
OPTIONS	Given in a later section.
ARGUMENTS	A file name or a directory name. If no file or directory is named, list the current directory.

If you type 1s at the shell prompt, the system will display an alphabetical listing of the file and directory names in the *current* working directory. For example:

\$ 1s
bin
bag.acct
gen.memo
letters
memos
midwest
notes
north
south

If your current directory is empty, nothing will happen except that the system displays the shell prompt again: \$ ls \$

Command Arguments

An argument gives the system information that is required to process a specific command or to change the *default*, or standard, behavior of a command. Some commands require one or more arguments; for others, arguments are optional. An argument usually consists of a file, directory, or user name. Refer to the reference manuals for your system to determine the requirements of each command.

1s is an example of a command that accepts a file or directory name as an optional argument. If you type 1s followed by a file name, the system redisplays the file name if the file exists in the current directory:

```
$ ls notes
notes
```

If a directory name is used as the argument, the system displays the names of all the files and directories in that directory:

```
$ ls letters
fox.ltr
lit.ltr
```

Command Options

An option (sometimes called a flag) is a special kind of argument that is specific to a particular command. As its name implies, an option is not required, but it provides additional versatility when used with a command. Most options are preceded by a dash (-). Some UNIX System commands can accept both arguments and options.

The 1s command has several options. The -1 or "long form" option is illustrated here. If you type 1s -1, the system lists not only the names of the files and directories in the current directory, but also the owner, file access protections, size in bytes, and time of last modification for each file and directory (some of these file attributes are discussed in the section "ADDITIONAL INTERACTIVE UNIX SYSTEM COMMANDS"). A typical directory listing looks like this:

```
$ ls -1
drwxr-xr-x 3 tony staff
                         69979 Apr 2 14:41 bin
                         30873 Apr 16 09:02 bag.acct
-r--r-- 1 bobr staff
-rwxrw-r-- 1 tony staff
                              2 Apr 7 13:24 gen.memo
drwx----- 2 tony staff
                         6107 Apr 2 10:48 letter
-rw-r--r-- 1 tony staff
                         52709 Apr 8 16:41 memos
-rw----- 1 tony staff
                          1338 Apr 16 13:04 midwest
-rw-rw-rw- 1 tony staff
                         34395 Apr 20 11:43 notes
-rw----- 1 tony staff
                         44978 Apr 17 16:32 north
-rw----- 1 tony staff
                           922 Apr 17 11:21 south
```

You will learn more about the output of this command in later sections.

Who is on the System (who)?

After you have logged in, you can use the who command to see a list of all users who are currently logged in.

COMMAND NAME	who
FORMAT	who [ami]
DESCRIPTION	List the users logged into the system.
OPTIONS	Not presented in this document.
ARGUMENTS	List the information for the user only.

The system displays the name, the terminal ID, the date, and time of login for each user logged into the system:

\$ who barbara tty4 Mar 15 08:44 michael console Mar 15 07:23 terryr tty10 Mar 15 09:02

Use who with the arguments am i to determine the login information for the terminal you are using:

\$ who am i
tony console Mar 15 07:23
\$

What Day is it (date)?

You can use the date command to find out the date and time.

COMMAND NAME	date
FORMAT	date
DESCRIPTION	List the current date and time.
OPTIONS	Not presented in this document.
ARGUMENTS	Not presented in this document.

The date command displays output similar to this:

\$ date Wed Mar 15 11:53:14 EST 1987

What's in This File (cat)?

The cat command is used to display the contents of a file on the terminal screen.

COMMAND NAME	cat
FORMAT	cat [-s] [file name(s)]
DESCRIPTION	Print one or more files on your terminal screen. If more than one file name is supplied, it is "con <i>cat</i> enated" to (added onto the bottom of) the previous file and printed.
OPTIONS	-s Be silent — do not comment about files that do not exist.
ARGUMENTS	The file name(s) in the order that you want them to print.

For example, to view the contents of the file /etc/password (the system file that stores information about each user ID on the system), type:

\$ cat /etc/passwd

The system displays the contents of the file on your screen. If the file is a long one, the system will scroll the contents on your screen. To initiate a pause in the scrolling, hold down the $\boxed{\text{CTRL}}$ key and simultaneously press $\boxed{\text{s}}$. To resume scrolling, hold down the $\boxed{\text{CTRL}}$ key and simultaneously press $\boxed{\text{q}}$.

To display the contents of two files, use the cat command followed by the two file names, which are separated by spaces:

```
$ cat /etc/passwd /etc/group
```

In the previous example, the file /etc/passwd is displayed, followed by the file /etc/group.

INTERACTIVE UNIX SYSTEM MANUAL ENTRIES

One type of documentation used for virtually all UNIX-based Systems is the reference manual, which consists of *manual entries*. Manual entries follow a specific format that may be confusing without some explanation.

INTERACTIVE UNIX System entries and the standard UNIX System Laboratories, Inc. (USL) manual entries are grouped alphabetically within the following sections:

- Section 1 system commands
- Section 2 system calls
- Section 3 subroutines
- Section 4 file formats
- Section 5 miscellaneous facilities
- Section 7 special files
- Section 8 miscellaneous

Section 6 is no longer used. For the INTERACTIVE UNIX Operating System, manual entries for users and system administrators are located in the *INTERACTIVE UNIX System User's/System Administrator's Reference Manual*. (All of the commands discussed in this document can be found in this reference manual.) Manual entries for programmers are found in the *INTERACTIVE SDS Guide and Programmer's Reference Manual* that accompanies the optional INTERACTIVE Software Development System extension. Some of the optional software packages available to run on the INTERACTIVE UNIX Operating System also contain manual entries as part of their documentation.

Manual entries located in the reference manuals may also be found on-line if your system administrator has installed them on your system. If installed, type man and the entry name to see the text of that entry on your screen.

Reading a Manual Entry

Manual entries all follow a similar format. Only the Section 1 entries (commands) are discussed here, since as a new user you are most likely to need the information there. Entries in other sections follow the same general rules.

Every entry contains certain headings. An entry *always* has a name line, a synopsis, and a description. Other sections are added as needed.

Here is a typical manual entry for a simple user command, cat.

cat(1)

cat(1)

NAME

cat - concatenate and print files

SYNOPSIS

cat [-u] [-s] [-v] [-t] [-e] file ...

DESCRIPTION

cat reads each file in sequence and writes it on the standard output. Thus:

"cat file"

prints the file, and

cat file1 file2 > file3

concatenates file1 and file2 and writes the result in file3.

If no input file is given, or if the argument - is encountered, *cat* reads from the standard input file. The following options apply to *cat*:

- -u The output is not buffered. (The default is buffered output.)
- -s cat is silent about nonexistent files.
- Causes non-printing charcters (with the exception fo tabs, new-lines, and form-feeds) to be printed visibly. ASCII control characters (octal 000 037) are printed as ⁿ, where n is the corresponding ASCII character in the range octal 100 137 (@, A, B, C, ..., X, Y, Z, [, \,], [^], and _); the DEL character (octal 0177) is printed [?]. Other non-printable characters are printed as M-x, where x is the ASCII character specified by the low-order seven bits.

The following options may be used with the -v option:

- -t Causes tabs to be printed as \hat{I} 's and form-feeds to be printed as \hat{L} 's.
- -e Causes a \$ character to be printed at the end of each line (prior to the new-line).

The -t and -e options are ignored if the -v option is not specified.

WARNING

Redirecting the output of *cat* onto one of the files being read will cause the loss of the data originally in the file being read. For example, typing:

cat file1 file2 >file1

will cause the original data in file1 to be lost.

SEE ALSO

cp(1), pg(1), pr(1).

Figure 1. The cat(1) Manual Entry

The Name Line. The name line contains the name of the command and a brief description of its function.

The Synopsis Line. The synopsis is a line (or set of lines, if the command is more complicated) that summarizes how the command is stated at the system prompt with its options and arguments. The command is shown in bold face; options are bold and are always shown inside square brackets []. *file* is the argument needed for the command (a file name) and the three dots "..." mean that you can give more than one file name at a time as arguments.

The Description Section. The description is just that -a description of how the command and its options function. For example, in cat(1) above, the description begins, "cat reads each file in sequence and writes it on the standard output." (The standard output device is your terminal screen. This is discussed in the section titled "USING THE SHELL.") It then shows you how to "cat" more than one file at a time and direct the results into a third file. The rest of the description gives details about using various options.

The See Also Section. This section contains cross references to other manual entries or documentation that contain information of related interest.

Miscellaneous Sections. Other sections found in various manual entries include the Warnings or Caveats section, which alerts you to possible problems when using the command in certain ways; the *Example* section, which contains an example using the more complicated commands; the *Files* section, which contains the system files in which the command is located; the *Diagnostics* section, which contains error messages of interest to programmers who may be using the command in a program; the *Bugs* section, which alerts you to known problems with the command; and the *Notes* section, which contains helpful hints or information that does not really fit anywhere else.

INTERPRETING INTERACTIVE UNIX SYSTEM ERROR MESSAGES

If something goes wrong when you use an INTERACTIVE UNIX System command, the system usually generates an *error message* to help you determine why the command did not work. Error messages are typically generated when you misspell a command or file name, when a command cannot be automatically accessed from your account, or when a file or directory name does not exist. Error messages on the INTERACTIVE UNIX System can be terse and cryptic. However, as you gain experience with the system, you will become more adept at deciphering them.

If you fail to provide the correct spelling for a command or file name, an error message is displayed on your screen. For example, if you type \$ datte instead of date, the system displays this error message:

\$ datte
datte: not found

The INTERACTIVE UNIX System also generates an error message if you fail to use space to separate the command name from its arguments. For example, if you type 1s-1 instead of 1s-1, the system generates the same message:

\$ ls-l
ls-l: not found

Some common error messages are:

command name: not found

You may have misspelled the command or forgotten a space that was needed. Check your spelling and try typing the command again. If the problem persists, then either your search path does not include the directory where the command is stored or the command is not available on your system. Check with your system administrator.

directory name: bad directory

You may have misspelled a directory name, but this message also appears if the directory does not exist. Check your spelling or cd to the parent of the directory you are trying to reach and verify that the directory exists and that you have the correct spelling of its name. If you get this message while trying to cd into a directory, it may be that you do not have execute permission for that directory. Check the permissions for the directory by using the ls -l command while in the parent directory.

Invalid argument

You have used an argument that the command does not accept. Try typing the name of the command without an argument. The system will often display a message that describes how to use the command. You should also check your command reference manual for the correct arguments.

No such file or directory

You have specified the name of a file or directory that does not exist. Often this means that one of the names in your path name is misspelled. Check your spelling and try again. If the problem persists, cd to the parent of the directory you are trying to reach and verify that the directory exists and that you have the correct spelling of its name.

Permission denied

You do not have permission to write in the named directory or to perform some operation on the named file. Check the permissions of the target with 1s -1. Change them or have the owner of the file or directory change them, as necessary.

Usage: {mv|cp|ln} f1f2

(mv|cp|ln) f1 ... fn d1 mv d1 d2

You have failed to specify a mandatory argument or have specified arguments in the wrong order while using cp, mv, or ln. This type of message shows the correct usage.

INTERACTIVE UNIX SYSTEM DIRECTORY STRUCTURE

On an INTERACTIVE UNIX Operating System, information is stored in an organized structure, called a *hierarchical file system*. It is called hierarchical because of its multi-level structure. A single master directory is at the top level, and additional files and directories are defined at various levels below it.

A file system is a collection of individual files and directories that are stored on a portion of a disk.

The master directory for the entire system is called the *root direc*tory. It is the first directory in the file system structure and is named slash (/). The root directory contains several directories, and each of these directories can contain other directories. Because the INTERACTIVE UNIX System file system is sometimes visualized as a "tree," each new directory created on the system can be viewed as a new branch added to the directory tree.

Here is a diagram of a simple directory structure for a computer user named Diane:

The root directory, (/), contains a directory named diane. /diane contains two directories: vendors and orders. These in turn, hold other files and directories. When Diane logs in, she is automatically placed in her home directory, /diane.

Because the INTERACTIVE UNIX System file system is very flexible, the organization of your files and directories can be changed at any time to fit your needs. For example, you might have a subdirectory in your home directory called memos, which contains all the memos you have written. Or, you could have a letters directory, which could contain a number of other directories, one for each of your major projects:

If you deal with different regional offices, you might have a major subdirectory for each region, with each subdirectory containing parallel directories for sales figures, letters, memos, and forecasts:

The only limit on the number of files and directories you can have, or the number of directory levels you can have, is the amount of disk space available to you.

File and Directory Naming Conventions

All programs, text, and data on disks or diskettes reside in files. Each file or directory has a unique name. The INTERACTIVE UNIX System is case sensitive, which means that it distinguishes between upper- and lowercase letters. INTERACTIVE UNIX System file and directory names can be one to fourteen characters long and can include both uppercase and lowercase letters. Although some symbols may be used in INTERACTIVE UNIX System file and directory names, it is safest to limit names to alphanumeric characters (a - z and 0 - 9) and the period (.).

Some symbols have special meanings to the INTERACTIVE UNIX Operating System. Never use an asterisk (*), a question mark (?), a greater than symbol (>), a lesser than symbol (<), an ampersand (&), or a vertical bar (!) in a file or directory name. You will learn more about how these symbols are interpreted by the UNIX System shell in later sections.

Path Names

When you want to access a directory or file in the file system, you use a *path name*. A path name is a sequence of directory and file names, separated by slashes, that designates the location of a particular file or directory. Since the *full path name* is actually the complete name of the file or directory, it ensures that no two directories (or no two files) on the system have exactly the same full name. To use the filing cabinet analogy again, you could locate a letter addressed to John Smith using its "path name," by saying it is in the second cabinet drawer, behind the divider marked "Boni Project," in a folder marked "letters."

There are two kinds of path names, a full (or *absolute*) path name and a *relative path name*. A full path name *always* begins with a slash (/) and consists of the sequence of directories from the root directory to the file or directory you wish to access. A relative path name does *not* begin with a slash. It describes the location of the target file or directory relative to your current location.

A full path name consists of a slash followed by one or more directory names separated by slashes and ending with the name of the target file or directory. The slash at the beginning of the path name tells the system to begin its search for the target from the root directory. For example, the full path name for the file that contains user Tony's eastern region August forecast might be:

/tony/east/forecasts/august

A relative path name omits all directory names up to and including the current directory from the path name. It tells the system to begin the search for the target file or directory from the current directory. You can access a file in your current working directory by using its relative path name. In this case, the relative path name consists of only the file name. Or, you can use the relative path name to access a file in a subdirectory of your current working directory by specifying the name of the subdirectory followed by a slash and the name of the file. For example, user Diane can display the contents of the southcity file in the orders subdirectory of her current working directory by using the relative path name with the cat command:

cat orders/southcity

It is not necessary to use the full path name to the file, /diane/orders/southcity.

Where Am I (pwd)?

If you work in a number of directories on many different projects, you may occasionally forget where you are working. The INTERACTIVE UNIX System command pwd (print working directory) will tell you where you are in the directory structure.

COMMAND NAME	pwd
FORMAT	pwd
DESCRIPTION	Print the current working directory. Prints the complete path name of the directory you are currently in.
OPTIONS	None.
ARGUMENTS	None.

Use the pwd command to see the full path name of your current directory. If you have just logged in, the system should respond with the name of your home directory:

\$ pwd /tony

Creating a Directory (mkdir)

It is a good idea to organize your files by filing them in subdirectories. Use the mkdir command to make new directories.

COMMAND NAME	mkdir
FORMAT	mkdir name(s)
DESCRIPTION	Make a directory with the name given.
OPTIONS	None.
ARGUMENTS	The name(s) of the directory(ies) you want to create.

Use the mkdir command to make a new directory called notes:

\$ mkdir notes

A notes directory is created, but you are *not* automatically moved into it. You remain in the directory from which you issued the command. To verify that the new directory was created, use the 1s command:

\$ ls
notes

Remember, follow all commands with **ENTER** unless otherwise instructed.

Changing Directories (cd)

Use the cd command to move from one directory to another.

COMMAND NAME	cd
FORMAT	cd [pathname]
DESCRIPTION	Change current directory. If no argument is given, cd moves you to your home directory.
OPTIONS	None.
ARGUMENTS	The path name (full or relative) of the directory to which you want to move.

For example, to move from your home directory to a subdirectory called notes, type:

\$ cd notes

You could use the full path name, but using the relative path name is much easier. To return to your home directory, type cd. Using the cd command with no arguments always returns you to your home directory. To use the cd command with a full path name, type:

\$ cd /tony/notes

What's in This Directory (1s)?

Use the 1s command to check the contents of a directory. The 1s command lists all the files and directories in a named directory.

COMMAND NAME	ls
FORMAT	ls [-ltau] [<i>name(s)</i>]
DESCRIPTION	For each directory named, alphabetically list its contents (no options requested) and any other information requested; for each file named, list the requested infor- mation.
OPTIONS	 -1 List in long format the mode, number of links, owner, group, size, and time of last modification. -t Sort contents by time of last modification (latest first) rather than by name. -a List all entries, including files that begin with a dot (.). -u Use time of last access instead of last modification for sorting (with -t option) or printing on the screen (with -1 option).
ARGUMENTS	A file name or a directory name. If no file or directory is named, it gives the current directory.

If your current directory is empty, the 1s command simply generates a new prompt:

\$ ls \$

The 1s command accepts a file name, directory name, or path name as an argument. If you use a file name as an argument, 1s simply lists the name of the file if it exists:

\$ cd /etc
\$ ls profile
profile

If you use the -1 option (as shown in the new command format), 1s lists more detailed information about the file:

\$ ls -l profile
-rw-r--r-- 1 bin staff 460 Jun 13 1984 profile
Copying a File (cp)

COMMAND NAME	cp
FORMAT	cp filename pathname
DESCRIPTION	Copy the named file to the named destination.
OPTIONS	None.
ARGUMENTS	The name of the file you want to copy and the its destination.

The cp command is used whenever you need to make a copy of a file. You may want to copy a file if you require several slightly different versions of a letter or if you plan to base a report or presentation on existing material.

To create a new file called employees that is an exact duplicate of the file all.emp in your current directory, use the cp command:

```
$ cp all.emp employees
```

The cp command may be used to copy a file in someone else's directory to one of your directories, or to copy a file in your directory to another name or location. You must have the read (r) permission for a file to copy it from someone else's area. Refer to the chmod command in the section "ADDITIONAL INTERACTIVE UNIX SYSTEM COMMANDS" in this primer for information on file permissions.

To copy a file that resides in another user's directory, you can use a full or relative path name to access the file:

```
$ cp /susan/letters/sales.ltr susan.ltr
$ ls
other.ltr
susan.ltr
```

When you copy a file from another directory, you may use the same file name or you may use a new file name. The only restriction is that you do not already have a file with the same name in your current directory. If you do, you will overwrite the contents of your existing file with the contents of the new file. This happens without a warning from the INTERACTIVE UNIX System. When you use the copy command to copy the contents of one directory to another directory, the directory you are copying to must already exist.

Path Name Shortcuts: Dot and Dot Dot

The INTERACTIVE UNIX System provides many shortcuts to help make life a little easier and to minimize typing. A relative path name is one type of shortcut. Two other shortcuts are dot (.) and dot dot (..).

One "dot," when used in place of a directory name, indicates that the command should use the current directory. This shortcut is useful when you are copying or moving files from another directory to your current directory.

For example, you may use the dot (.) shortcut to copy a file into your current directory and give it the same name:

```
$ cp /susan/letters/sales.ltr .
```

Two "dots," when used in place of a directory name, indicate the directory directly *above* your current working directory. The directory above your current directory is also known as the *parent directory*.

You can use .. to move quickly to a parent directory. For example, if you are currently located in the directory /tony/east/letters and want to return to the directory named east (the parent directory of your current directory), simply type:

\$ cd ..
\$ pwd
/tony/east

You can also use a series of "dot dots" to move more than one directory at a time. For example, to move to the root directory from the directory /tony/east/letters, type:

```
$ cd ../../..
$ pwd
/
```

Removing a File or Directory (rm, rmdir)

The rm command allows you to remove a file or directory you have created.

COMMAND NAME	rm, rmdir
FORMAT	<pre>rm [-fri] [file name(s)] rmdir [directory name(s)]</pre>
DESCRIPTION	Remove the named file or directory.
OPTIONS	 f Ask no questions about removal. i Ask before removing each file or directory. r Examine each directory before removing it.
ARGUMENTS	One or more file or directory names.

To remove a directory, you must first remove all of the files in that directory. Generally, the system will not allow you to remove a directory that contains files.

Use the ls -a command to display all files in the letters directory, including hidden files (those with file names that begin with a dot):

```
$ ls -a
.
.
.index
lit.ltr
confirm.ltr
```

Use rm to remove all the files in the directory except . and ... These are special file names used only by the system; they cannot be removed. To remove the files: \$ rm .index confirm.ltr lit.ltr

To remove the letters directory, you must cd out of it, then use rmdir to remove it:

\$ cd ..
\$ rmdir letters

INTRODUCTION TO UNIX SYSTEM EDITORS

An *editor* is a program that is used to enter and modify text and data. There are two basic types of editors: *line editors* and *full-screen editors*. When using a line editor, you must explicitly specify the line or lines you want to edit. You do not see the changes to your file as they occur. A line editor is useful if you are using a hardcopy terminal, i.e, one that does not have a screen. A full-screen editor allows you to see the changes made to a file as you make them. Screen editors are the most popular type of editor today.

Most UNIX Systems have a line editor and one or more full-screen editors. This section outlines three of the most commonly available editors on UNIX Systems; it does not attempt to explain how to use a UNIX System editor. Refer to the "Documentation Roadmap" in the *INTERACTIVE UNIX Operating System Guide* to determine where you can find tutorials that describe the editors available on your system.

The ed Line Editor

ed is the standard editor provided on every UNIX System. It is a line-oriented editor and was originally developed to run on terminals without screens. ed is not the editor of choice for most users since you cannot see changes and additions to a file in context. It uses two command "modes" (insert and command) and, in traditional UNIX System fashion, the editing commands are terse and cryptic. However, it is a very powerful editor for making global changes to a file, and it offers some advantages when you are editing text over slow telephone lines or on a terminal without a terminal definition for the available screen editor. Sometimes it is the only editor available, so it is useful to know a little about ed. Refer to the "Documentation Roadmap" to find references on how to use ed.

The vi Screen Editor

vi is one of the most widely used UNIX System screen editors. It was originally developed at the University of California at Berkeley, but it is now distributed as part of USL's UNIX System V.3. It is also distributed by many other UNIX System vendors. vi is an extremely flexible and powerful editor. It provides many tools and features that programmers find especially useful. vi also uses two modes to perform editing tasks: command and insert. The user must toggle back and forth between the two modes to edit text. All commands, including those that move the cursor keys, must be issued while in command mode. Adding text to a file must be done in insert mode. This means that if you notice an error several lines above your current line, you must change to command mode to move the cursor back up to the error and delete the erroneous characters; return to insert mode to type in the correct text; then change once more to command mode to return to the current work. Some users find that switching modes while editing text can be difficult and time consuming, while other users have very little trouble using the editor efficiently.

Refer to the "Documentation Roadmap" to find references on how to use vi.

The TEN/PLUS User Interface

TEN/PLUS is a full-screen *user interface* to the UNIX System. It is based on a full-screen editor (the TEN/PLUS editor) developed by INTERACTIVE Systems Corporation to take the mystery out of text editing programs and the UNIX System. It is available on many systems today, including IBM's AIX*, PC/IX, and IX/370, as well as IN/ix* systems available from Wang, SCI, Hitachi, and others.

The TEN/PLUS editor does not rely on modes to perform editing operations; it uses ten basic function keys to perform most editing tasks and is very easy to learn. For a novice user, it is probably much easier to learn TEN/PLUS than the standard UNIX System editors ed and vi. The TEN/PLUS editor also includes a large number of advanced editing features to make modifying text files easier.

Refer to the "Documentation Roadmap" to find references on how to use the TEN/PLUS editor.

USING THE SHELL

Introduction

The INTERACTIVE UNIX Operating System consists of two major components, the *kernel* and the *shell*. The kernel is the core of the operating system. It is the part of the *system software* that is responsible for managing the computer's *hardware* and *software* resources and for processing commands. The work that the kernel performs is hidden from most users by the shell.

The shell is the part of the system that interacts with the user. It is also known as the command interpreter and is sometimes referred to as the user interface. It is responsible for passing user commands to the kernel for processing and for returning the results to the terminal screen, into a file, or to another device, such as a printer.

There are currently several versions of the shell available on UNIX Systems. The two most popular versions of the shell are known as the *Bourne shell* and the *C shell*. The Bourne shell was written at Bell Laboratories and released by AT&T (now USL). The C shell was written and released by the University of California at Berkeley. You should ask your system administrator or refer to your system reference guide to determine which version is available on your system. The Bourne shell is considered to be the standard UNIX System shell, but the C shell has gained widespread popularity, particularly with programmers. The information in this primer generally applies to both versions of the UNIX System shell.

When you have successfully logged into your computer, you are automatically in contact with the shell. As you learned earlier, the prompt you see on the screen is also known as the shell prompt. If you do not see a shell prompt and you are sure that you are logged into the system, your system may also include a friendly user interface. On some systems, the TEN/PLUS User Interface is included. In this case, the shell is still running, but it is hidden from you in order to provide an even easier method of executing commands and running applications.

Shell Features

Although the shell is an ordinary program that is run by the kernel, it is a very versatile program. Not only does it perform the work of the command interpreter, but it also functions as a programming language. The shell can take commands from special files called *shell scripts* or *shell programs*. A shell script can be a simple collection of shell commands such as those normally executed on the command line, or it can be a program that uses programming logic, variable assignment, and argument processing to perform complex tasks. Shell programming is beyond the scope of this primer, but it is covered in more detail in other documentation resources. Refer to the "Documentation Roadmap" for more information.

In addition to being a programming language, the shell has a number of distinctive features that permit even the novice user to perform sophisticated operations with a little practice. They include:

- File name shortcuts known as wildcards.
- The ability to *redirect* the input and output of a command to a file, a printer, or another program.
- The ability to use the output of one command as the input to another command, also known as a *pipeline*.
- The ability to run two or more programs simultaneously by using *background* processing.

Each of these features is described in the following sections.

Using Wildcards

Many INTERACTIVE UNIX System commands require one or more file or directory names as arguments to the command. A wildcard is used to match a character or a string of characters in a file or directory name. It is another type of shortcut. (You have already learned two shortcuts for relative directory names, . and ...) A wildcard is also referred to as a *pattern matching character*. Wildcards are handy because they enable you to use a file name or group of file names without having to type the complete name. It is much easier to move all the files from one directory to another using a wildcard than to type out all the file names. Wildcards can also be used when you only remember part of a file name.

There are three wildcard characters:

- ? Matches any single character
- * Matches one or more characters
- [...] Matches an array of characters
- When you create new files, be very careful not to use a wildcard character as part of the file name. It can be difficult to access or remove a file if there is a wildcard character in its name.

WILDCARD	?
FORMAT	string? ? string ? string? string? ?
DESCRIPTION	Substituting a question mark in a file or directory name argument matches one single character for each ? supplied.

A directory called misc might contain the following files:

letter1 letter01 letter10 repairs letter2 letter02 letter.mmb reporta letter3 letter03 letter.pc reportb

To remove the files named letter 1, letter 2, and letter 3, type:

\$ rm letter?

All of the other files will remain, either because they do not start with the string letter, or because they have more than one character following the string letter.

```
$ ls
letter01
letter02
letter03
letter10
letter.pc
repairs
reporta
reportb
```

To remove the files named letter01, letter02, and letter03, you cannot use the command rm letter?? because that would also remove the file letter10. Instead, type:

```
$ rm letter0?
```

because it removes only the files with one character following the string letter0.

```
$ 1s
letter10
letter.mmb
letter.pc
repairs
reporta
reportb
```

WILDCARD	*
FORMAT	string* * string * string* * string* string
DESCRIPTION	Substituting an asterisk in a file or directory name argument tells the computer to match a string of characters (zero or more characters).

To list the names of all files beginning with the letters re in the misc directory, use the wildcard * with the ls command. This matches any string of characters beginning with re:

```
$ ls re*
repairs
reporta
reportb
```

To list the names of only the files with the character "dot" (.) in them:

\$ ls *.*
letter.mmb
letter.pc

Sometimes, it is very useful to use the * wildcard in conjunction with the rm command to remove all the files in a directory:

\$ rm *

This is a very dangerous command! Be very sure that you really want to remove all of the files in the directory before you use this command. Your files will be permanently lost!

WILDCARD	[]
FORMAT	string[n-n] string [n-n]string [n,n,n-]string
DESCRIPTION	Substituting a list of characters between square brackets in a file or directory name used as an argument to a command tells the computer to match any characters present in the array.

To list all the letter files in the misc directory that end in a number, you could use the [...] wildcard:

```
$ ls letter[0-9]
letter1
letter2
letter3
```

Or, to list only those letter files that end in the numbers one and two, type:

```
$ ls letter[1,2]
letter1
letter2
```

Redirection of Input and Output

Every command to the computer requires input and produces output. Normally, INTERACTIVE UNIX System commands take their input from the *standard input* and direct it to the *standard output*. The standard input is usually taken from your terminal keyboard. For example, when you type a command and press **ENTER**, you are sending standard input to the kernel. The standard output is usually your terminal screen, although some programs write their standard output to a file or a printer. When you type the 1s command, for example, the standard input is taken from your terminal keyboard and the standard output is written to the terminal screen.

A very important feature of the INTERACTIVE UNIX System is the ability to direct a command to take its input from a source other than its standard input, and to send its output to a destination other than its standard output. For example, you can direct a command to take its input from a file already stored on the computer and to direct its output to another file or to a device such as a printer. The ability to take input from one place and direct it to another at the time you start a process is called *redirection of input/output (I/O)*.

Two symbols are used to indicate I/O redirection. The "greater than" (>) symbol redirects output, and the "less than" symbol (<) redirects input. Since you will probably redirect the output of a command (>) more frequently than you redirect the input (<), input redirection is not discussed in this primer. Refer to the User's Guide for more information on input redirection.

I/O redirection is commonly used to store the output of a command in a file, perhaps to be used with another command or to be incorporated into a file or a message. For example, if you need a listing of all the files in your current directory to use in a report, you could use this command:

\$ ls > files.list

The system automatically creates a new file called files.list and writes the output of the ls command in that file. You will not see any output on your screen. If you want to verify that the redirection worked, you can use the cat command to view the contents of files.list: \$ cat files.list
letters
memos

To create one large file out of two smaller files, use the cat command and redirect the output to a new file:.

```
$ cat /etc/passwd /etc/group > users.groups
```

The two files will be written, one after the other, into the file called users.groups. The contents of the files /etc/passwd and /etc/group are not changed, moved, or harmed in any way by this process. The command simply causes a copy of the file's contents to be placed into the named file.

■ When redirecting output, you must be careful not use an existing file name as your output destination. You can overwrite the contents of the existing file if the file's permissions allow it, thereby losing all the text or data in it. (You will learn more about file permissions in the discussion of the command chmod in the section "ADDITIONAL INTERACTIVE UNIX SYSTEM COMMANDS.")

For example, assume Tony owns a file called widgets that is located in his home directory. He wants to put a copy of Barb's eastern widgets file into his directory, but he has forgotten that he already has a file named widgets in his home directory. If Tony types the command:

```
$ cat /barb/widgets/east.wid > /tony/widgets
```

the contents of his original widgets file is deleted and replaced with the contents of Barb's file. The file is still named widgets. It is a good idea to check the file names in your destination directory with 1s before performing an operation like this.

To redirect the output of a command and store the results at the end of a file that already exists *without* overwriting the contents of the file, use two greater than (>>) symbols.

Tony could have *appended* (added to the bottom) the contents of Barb's east.wid file onto the end of his widgets file with this command:

```
$ cat barb/widgets/east.wid >> tony/widgets
```

Pipes and Filters

The UNIX System is extremely flexible. It was built on the philosophy that utilities on the system should build on the work of other utilities and be reusable. There are two special notions that are important to UNIX Systems: *pipes* and *filters*.

A filter is a program that accepts input from one source, performs the appointed task on the data, and then writes the results to another place without changing the input file in any way. For example, sort takes as its input the file you designate, sorts all of the lines in alphabetical order, and displays it on your terminal. The sort command is an example of a simple filter.

COMMAND NAME	sort
FORMAT	<pre>sort [-dfn] [-ooutput file] [file name(s)]</pre>
DESCRIPTION	Sort the lines of the named file(s) together and write the results to standard output. If no input files are given, it sorts standard input. If no output file is given, it writes to standard output.
OPTIONS	 -d Use "dictionary" order. Only letters, digits, and blanks are significant. -f Ignore case when sorting. -n Sort numeric strings arithmetically.
ARGUMENTS	The name of the file you wish to be the output file, preceded by $-o$, and the name(s) of the file(s) you wish to sort.

A pipe is a connection between two or more commands. To create a pipeline, you execute a command and pass its output ("pipe" its output) so that it becomes the input for the next command. A pipe is indicated by a vertical bar (1). Two filters are often used to create a pipeline. The output of a pipeline can be displayed on the screen or it may be redirected to a file.

The sort command is a filter that is frequently used in pipelines. For the following example, assume you have two files: east.emp and west.emp. The first file (east.emp) is a list of employees in the Eastern Regional Office, and the second file (west.emp) is a list of all the employees in the Western Region. To create a single file that contains a list of all the employees in the Eastern and Western regions sorted alphabetically, use the following command:

\$ cat east.emp west.emp ! sort -d > all.emp

You have taken the output from cat, piped it to sort, and redirected sort's output into a file called all.emp.

To perform the same task but redirect the output of sort to a printer instead, use this command line:

```
$ cat east.emp west.emp | sort -d | lp
```

To learn more about the sort command, see your INTERACTIVE UNIX System documentation. The 1p command is discussed in greater detail in "ADDITIONAL INTERACTIVE UNIX SYSTEM COMMANDS."

Background Processing

The INTERACTIVE UNIX System is an *interactive* operating system, which means that you can carry on a dialogue with the computer. Normally, you issue a command and wait for the shell to process your command and return the shell prompt. Sometimes commands can take a long time to complete and do not require any assistance from you. Waiting for the command to finish can be tedious and a waste of time.

To alleviate this situation, the INTERACTIVE UNIX System allows you to request that a command be run in the background. This means that the system starts the process, displays the process identification number (PID) associated with the process, and then returns the shell prompt. The process continues to run until it is completed, while you continue to use the system for other work. To request background processing, type an ampersand (&) at the end of the command line, immediately before pressing **ENTER**.

Many commands, such as 1s, complete so quickly that it does not make sense to run them in the background. However, if you are formatting a document or compiling a program, you will find the ability to run a command in the background very useful. Here is an example of a command line where the user requested that it run in the background:

```
$ cat east.emp west.emp ¦ sort-d > all.emp&
432
$
```

The shell first gives you an identification number for the process (in this case, 432) and then returns the INTERACTIVE UNIX System prompt. You can now run another command. When your process in the background is finished, the output will be contained in the specified file.

Note that unlike processes being run in the foreground, a background process cannot be temporarily stopped by using $\boxed{\text{CTRL}}$ d or terminated using $\boxed{\text{DEL}}$. It can be stopped only by logging off or using the kill command.

ADDITIONAL INTERACTIVE UNIX SYSTEM COMMANDS

There are literally hundreds of commands available on the INTERACTIVE UNIX System. There are commands to format, extract, and print text in a file; compile, link, archive, and store program code; and report available disk space or commands that are currently running on the system. However, a typical user only needs to use about two dozen commands on a regular basis. We have already described some of the most useful commands in the preceding sections. This section will familiarize you with some other useful commands.

Changing Permissions (chmod)

Every file and directory on an INTERACTIVE UNIX System is associated with a set of *file access permissions*, or *protection modes*, that specify who will have access to it. There are three different types of *permissions*: "read," "write," and "execute."

Read permission

Allows a user to view the contents of the file or copy it to another area. Read permission does not allow the user to make changes to the file.

Write permission

Allows a user to make changes to a file. Write permission on a directory allows a user to create and delete files in that directory.

Execute permission

Allows a user to execute the file as an INTERACTIVE UNIX System command, if the file contains INTER-ACTIVE UNIX System command lines. Execute permission on a directory allows a user to cd into it. If you attempt to cd into a directory for which you do not have execute permission, the system will display the message *directoryname*: bad directory.

Each set of permissions applies to one of three categories of users: owner, group, and other. The "owner" of the file owns the file or directory. The "group" often consists of people working on the same project or in the same department and using the same files. Group membership is usually determined by the system administrator. "Other" refers to everyone on the system who is neither the owner nor in the owner's group.

User Category	Directories	Files	
User Group Other	read, write, execute read, execute	read, write read	

The default permissions associated with each file and directory are:

Use the 1s -1 command to look at file and directory permissions:

total 272

-rw-rw-rw-	1 linda	staff	625 Apr	7	13:24	letter01
-rr	1 linda	staff	69979 Apr	2	14:41	letter02
drwxr-x	1 linda	staff	2 Apr	7	13:24	notes
-rw-rw-rw-	1 billr	staff	30873 Apr	16	09:02	proj.info
-rwxr-xr	1 linda	staff	69979 Apr	2	14:41	save.memo

The access permissions appear on the left of the display.

Now look more closely at the permissions for the file save.memo:

File Type	<u>File Access Permissions</u>			
	rwx	r-x	r	
	A	A	♦	
	User	Group	Other	

The first column specifies the file type: a dash (-) indicates a file and a d indicates a directory. The first column for the save.memo file indicates that it is a file. The next three columns specify the read (r), write (w), and execute (x) permissions for the owner. In this case, the owner can read, modify, and execute the file. The next three columns specify the permissions set for the owner's group. The permissions indicate that members of the group can read and execute the file. A dash indicates that a permission is denied; therefore, members of the group cannot modify the file. The last three columns specify permissions for others on the system. Others are allowed to read the file but are denied permission to modify or execute it.

COMMAND NAME	chmod
FORMAT	chmod nnn filename(s) chmod nnn directory name(s)
DESCRIPTION	Change mode (permissions) of the named file or directory.
OPTIONS	None.
ARGUMENTS	The octal number or a character representation of the the new file access permissions and the name(s) of the file(s) or directory(ies) whose file access permissions are going to be changed.

The chmod command takes an argument, which may be in the form of a character representation (r, w, x) or a numeric representation (using *octal* numbers) to indicate the permissions in effect.

Each permission is associated with a number: read=4, write=2, execute=1, and no permission=0. The octal equivalents are obtained by adding together the numbers associated with the basic permissions. This table shows the octal equivalents for the basic permissions:

<u>Permission</u>	Octal representation
_	0
x	1
w	2
wx	3
r	4
rx	5
rw	6
rwx	7

To change the permissions of the save.memo file so that members of the group only are allowed to read the file, you can use the chmod command with the octal representation:

\$ chmod 744 save.memo

The numbers 744 are the octal equivalent of rwx, r, r. This gives the owner read, write, and execute permission in the file but allows only read permission to those in the group and others.

To make the same change using the character representation requires a slightly different approach. This table shows the character symbols and their definitions:

<u>Permission</u>	Definition
u	Permission applies to user (owner) only
g	Permission applies to group members only
0	Permission applies to others only
a	Permission applies to all (u, g, and o)
+	Add the indicated permissions
_	Remove the indicated permissions
r	Read permission
w	Write permission
х	Execute permission

To change the original permissions on the save.memo file so that group members are only allowed to read the file, use this command:

\$ chmod g-x save.memo

The g indicates permissions are being changed for members of the group, the minus sign (-) indicates removal of a permission, and the x indicates execute permission.

To remove read permission for the group and others on the file, use:

\$ chmod go-r save.memo

or:

\$ chmod 700 save.memo

The listing for the save.memo file would now look like this:

-rwx----- 1 linda staff 69979 Apr 2 14:41 save.memo

Moving a File or Directory (mv)

On many systems there is a "rename" command and a "move" command. On INTERACTIVE UNIX Systems these two tasks are combined into one command named mv. It is used when you want to change the name of a file or directory without making a copy of its contents. It is also used to move the contents of a file or directory from one place in the file system to another.

48

COMMAND NAME	mv
FORMAT	mv filename pathname mv directoryname pathname
DESCRIPTION	Move the named file or directory to the named position. If a directory name in the current directory is given as the destination for a file, the full path name is not needed.
OPTIONS	None.
ARGUMENTS	The name of the file or directory you wish to move and its destination.

When you move a file from one directory location to another, be sure that you do not already have a file with the same name in the new location. Like the cp command, if a file already exists with that name, it is overwritten. The mv command may be used to move a file from one directory to another or to rename a file. You must have the correct file access permissions to move a file from another user's area, i.e., you must have read, write, and execute (rwx) permission on the directory where the file resides.

To change the name of a file from all.emp to employees:

\$ mv all.emp employees

The contents of the file remains the same, but it has been renamed employees. There is no longer a file named all.emp.

\$ ls employees

To move the employees file into an existing subdirectory called payroll:

\$ mv employees payroll

Since you are moving a file into a directory, it is not necessary to supply the file name. The system simply moves the file into payroll, retaining the same file name. To rename the employees file to dec.pay and move it into the payroll subdirectory at the same time:

\$ mv employees payroll/dec.pay

Changing Owner (chown)

If you create a directory, you are the owner of that directory. In some cases, however, you may want to change the ownership of a file or a directory to someone else. Do this by using the chown command.

COMMAND NAME	chown
FORMAT	chown username filename(s)
	chown username directoryname(s)
DESCRIPTION	Change ownership of the named file or directory.
OPTIONS	None.
ARGUMENTS	The name of the user whom you want to own the file(s) or directory(ies) and the name(s) of the file(s) or directory(ies) you wish to change the ownership of.

To change the ownership of your file, local.wid, to Tony, use the chown command:

\$ chown tony local.wid

To change the ownership of all files in the directory to Tony, use the ***** wildcard:

\$ chown tony *

Once you have changed the ownership of a file, your access to that file is limited to what the permissions on that file allow. If you are changing the ownership of a file and want to continue to be able to write in it, be sure the permissions are set accordingly before you use chown. Of course, the new owner may change the permissions again.

Checking Spelling (spell)

The INTERACTIVE UNIX System includes a utility to check the spelling in a file. The spelling checker is not an interactive command, and it does not provide suggestions for alternative spellings.

COMMAND NAME	spell
FORMAT	spell filename(s)
DESCRIPTION	This command checks the spelling of the input file and lists the words that do not appear in its dictionary on the standard output (the terminal).
OPTIONS	Not presented in this document.
ARGUMENTS	Not presented in this document.

It is a good idea to redirect the output of the spell command to another file so that you may refer to it. For example, to check the spelling of the file notes, redirect the output of spell into the notes.er file, then cat the notes.er file:

```
$ spell notes > notes.er
$ cat notes.er
errir
teh
```

Once you have a list of errors, you can use a text editor to correct the spelling errors. If your text editor allows you to alternate between two files or has a windowing capability, it can be very useful to store the errors in a file that you can refer to while you are making corrections. The system does not recognize the acronyms and other special words that you might use, so spell may list some words that you know are not really spelling errors.

Viewing a File (pg)

You have already learned about the cat command as a way to view a file on the screen. The pg command provides another way to view a file on the screen. It is more convenient to use because it displays the text one page at a time to allow you time to read the screen. pg displays the next page of text when you press **ENTER**.

COMMAND NAME	ba
FORMAT	pg filename(s)
DESCRIPTION	Display the file(s) on the standard output, one page at a time. Use ENTER to display the next page. If a file name is not specified, pg reads from the standard input.
OPTIONS	Not presented in this document.
ARGUMENTS	Not presented in this document.

For example, to display the file letter02, type:

\$ pg letter02

Printing a File (1p)

After you have created a file, you may wish to obtain a printed copy of it. (This printed copy is often referred to as a hardcopy.) Use the lp command to print files on your company's printers.

COMMAND NAME	lp
FORMAT	lp filename(s)
DESCRIPTION	1p sends the named file to a printing device.
OPTIONS	Not presented in this document. Most offices have several different printers. See your system administrator for the options you should use to access your printers.
ARGUMENTS	The name of the file(s) you wish to print.

The 1p program queues each request (puts it in a line for processing) and prints the file as soon as the printer is free. A title page with the system date and time is also printed. 1p can be used in a pipeline with other commands if you want to send the output directly to a printer instead of to a file or the terminal screen. For example, to print the file letter02, type: \$ lp letter02

To get hard copies of two letter files, you can pipe the output of cat directly to the printer:

```
$ cat letter01 letter02 ¦ lp
```

Checking on Processes (ps)

To see what processes you are currently running, use the ps (report process status) command. This can be very useful when you need to stop a process or to check to see if it has stopped prematurely.

COMMAND NAME	ps
FORMAT	ps [options]
DESCRIPTION	Report the status of all currently active processes on the terminal.
OPTIONS	-f Generate a full listing.
ARGUMENTS	Not presented in this document.

For example, suppose you want to check to see if the spell command you started is still running in the background. Type ps. Your screen will look similar to this:

PID	TTY	TIME	COMMAND
312	ttyi03	0:00	ksh
323	ttyi03	0:00	ksh
325	ttyi03	0:00	spell
326	ttyi03	0:01	deroff
317	ttyi03	0:16	sort
318	ttyi03	0:00	spellpro
320	ttyi03	0:00	comm
321	ttyi03	0:00	tee
327	ttyi03	0:01	sed
331	ttyi03	0:00	comm
332	ttyi03	0:00	tee
333	ttyi03	0:00	ps

The spell process is still running and its process ID number is 325. If you do not see spell in the list, then the process has either completed running or died before it completed.

Killing a Process (kill)

At times you will want to stop a background process that is currently executing. To do this, use the kill command.

COMMAND NAME	kill
FORMAT	kill [-signo] process_ID_number
DESCRIPTION	Terminate the named process.
OPTIONS	-9 Send a sure kill signal.
ARGUMENTS	The ID of the process you want to kill.

To stop a process while you are still logged in, type:

kill *id_number*

where *id_number* is the identification number of the process.

If you do not remember the process ID number, use the ps (report process status) command described above to find it. Occasionally kill alone is not sufficient to stop a process. If this occurs, type:

kill -9 id_number

USING VIRTUAL TERMINALS

The INTERACTIVE UNIX Operating System contains a very useful feature, the *virtual terminal*, that allows you to log in several times simultaneously on a console terminal. When you switch from one virtual terminal to another, your screen clears and the processes you started in another login session continue to run in the background even while out of view. In one session you can be editing a file, while in others you can be running different programs.

Virtual terminals can be enabled only on a console terminal. By default in the INTERACTIVE UNIX Operating System, you can have one session on a console terminal plus two other virtual terminals. This number can be changed by the system administrator; up to seven virtual terminals can be enabled, for a total of eight possible login sessions.

Any privileges that require use of the console terminal, such as logging in as root, cannot be performed during the virtual terminal sessions. You can exercise such privileges only from your console login session.

Switching From One Virtual Terminal to Another

The virtual terminals that are enabled on your system are always ready for use. On most enhanced 386* keyboards, it is necessary to use **ALT** to perform a **SYS-REQ** function.

- 1. To switch to the first virtual terminal, press the ALT and SYS-REQ keys simultaneously, then release them and press F1.
- 2. When the new prompt appears, you may log in with your usual login ID and password:

```
VT1 login:
Password:
```

- To switch to the second virtual terminal, again press <u>ALT</u> and <u>SYS-REQ</u> simultaneously, then release them and press <u>F2</u>. Similarly, pressing <u>ALT</u> and <u>SYS-REQ</u> simultaneously, followed by <u>F3</u>, <u>F4</u>, <u>F5</u>, <u>F6</u>, or <u>F7</u> invokes virtual terminals 3 through 7, respectively. If the corresponding terminal is not enabled on your system, the terminal beeps.
- 4. To return to the system console, press ALT and SYS-REQ simultaneously, then release them and press F8.

- You can also cycle forward through all the currently enabled virtual terminals by repeating the following sequence: press
 ALT and SYS-REQ simultaneously, then release them and press F10. You can cycle backward through all the currently enabled virtual terminals by repeating the following sequence: press ALT and SYS-REQ simultaneously, then release them and press F9.
- 6. Each virtual terminal behaves as if it were an entirely separate terminal sitting on your desk. Therefore, in order to be completely logged out of the system, you must log out of each virtual terminal that you have logged in to.

Appendix A: ACCESSING DOS FILES

The INTERACTIVE UNIX Operating System provides two mechanisms for accessing MS-DOS* (DOS) files from the INTERACTIVE UNIX Operating System: the DOS File System Support (DOS-FSS) and the Dossette File Exchange Utility (dossette).

DOS-FSS allows a DOS file system to function as an integral part of the INTERACTIVE UNIX System partition. This facility allows multiple users to simultaneously access the DOS file system. DOS files need not be copied into the INTERACTIVE UNIX System partition but can be manipulated directly, using path names that are similar to those used on the INTERACTIVE UNIX System. And INTERACTIVE UNIX System commands and utilities can be used with DOS files, just as they would be used with any INTERACTIVE UNIX System file. DOS-FSS is recommended for high-volume situations that require access to and manipulation of many DOS files, using INTERACTIVE UNIX System commands and utilities. DOS-FSS can be used with both fixed disk partitions and diskettes.

dossette provides a specific set of commands for manipulating DOS-format file systems and for moving files between DOS and INTERACTIVE UNIX System file systems. dossette allows DOS files to be copied into the INTERACTIVE UNIX System partition and edited, then copied back into the DOS file system. Format conversions are performed automatically. dossette also includes commands for creating DOS directories, deleting DOS files, and printing DOS ASCII files on the terminal screen. dossette is easily invoked and provides a convenient method for accessing DOS files from the UNIX System in low-volume situations that require a limited amount of file manipulation. dossette can be used with both fixed disk partitions and diskettes.

USING DOS-FSS

Before You Begin

Under DOS-FSS, a DOS file system must be *mounted* on an INTERACTIVE UNIX System directory before it can be accessed; and a DOS file system must be *unmounted* in order to ensure that all data is written to disk. Superuser privileges are required to mount and unmount a file system. These procedures are usually performed by your system administrator.

- - Do not remove a DOS file system diskette from the disk drive until it has been unmounted, or you may lose data.

See your system administrator to ensure that your DOS file system is mounted and unmounted correctly. If you are the system administrator, refer to the "INTERACTIVE UNIX Operating System Maintenance Procedures" in the *INTERACTIVE UNIX Operating System Guide* for more information about mounting and unmounting a file system.

DOS File Names

The syntax used for DOS path names is different from that used for INTERACTIVE UNIX System path names. The INTERACTIVE UNIX System uses a series of directory names and (optionally) a file name, each separated by a slash (/). DOS uses a drive name (*device* specifier) followed by a series of directory names and (optionally) a file name, each separated by a backslash (\setminus). (A device specifier usually consists of an alphabetic character followed by a colon. For example, the device specifier a: usually indicates the first diskette drive and the device specifier b: usually indicates the second diskette drive.)

Your system administrator will mount your DOS file system under an INTERACTIVE UNIX System directory name, such as /dos. See your system administrator for the appropriate path name to your DOS file system.

Once the DOS file system is mounted under DOS-FSS, DOS files can be accessed in the same way that INTERACTIVE UNIX System files are accessed. DOS files now function as part of the INTERACTIVE UNIX System file system, so path names need not specify a device name. Instead, they follow the conventions for INTERACTIVE UNIX System path names, i.e., they are made up of directory and file names, each separated by a slash. The backslash character is not valid. For example, to look at the DOS file autoexec.bat in the /dos directory, you could use this command:

```
cat /dos/autoexec.bat
```

Note that the path name does not specify a device name and that the components of the path name are separated by slashes.

Under DOS, all file names are mapped to uppercase, regardless of whether they are typed in uppercase or lowercase. DOS-FSS provides this same mapping on input so that users accustomed to this feature can continue to specify DOS files using lowercase. Similarly, DOS file names are displayed in lowercase on output.

DOS-FSS also expands wildcard characters (* and ?). For example, the DOS file EXAMPLE.TXT residing in the current directory could be found using any of the following:

```
ls e*
ls e*.*
ls exam???.*
cat e*.txt
```

Refer to the section "Using Wildcards" in this primer for more information about wildcards.

File Conversion Utilities

Text files are stored differently under the DOS and UNIX Systems. The INTERACTIVE UNIX System uses the new-line character to specify the end of a line; DOS uses a carriage-return followed by a line-feed to specify the end of a line. Because of this, DOS files viewed through an INTERACTIVE UNIX System editor display control characters at the end of each line. DOS-FSS provides three utilities to convert DOS files to UNIX System format and UNIX System files to DOS format:

- dtou Converts DOS files to UNIX System format.
- utod Converts UNIX System files to DOS format.
- lef Determines the current format of the specified text file and converts it to the other format.

All three utilities take zero, one, or two arguments. If no argument is specified, the utility takes input from standard input (usually your keyboard) and sends output to standard output (usually your display screen). If one argument is specified, it is assumed to be the input file, and the output is sent to standard output. If two arguments are specified, the first is taken to be the input file and the second is taken to be the output file. The following examples illustrate the command format of the conversion utilities.

This command converts the DOS text file example.txt to a UNIX System text file and displays it on the standard output:

dtou /dos/example.txt

This command converts the UNIX System text file doc.txt to a DOS text file in the /dos directory:

utod /tmp/doc.txt /dos/doc.txt

This command uses the lef utility to determine the format of the doc.txt file, convert it from the current format to the other format, and place the new file in the /tmp directory:

lef /dos/doc.txt /tmp/doc.txt

Permissions

The INTERACTIVE UNIX System is a *multi-user* environment that makes use of such concepts as owners of and permissions for files and directories. (Refer to the section "Changing Permissions (chmod)" for more information about file owners and file permissions.) DOS is a *single-user* system and has no equivalent concepts. In order to support multi-user access to a mounted DOS file system, DOS-FSS attempts to apply these UNIX System concepts to the DOS file system.

If you cannot access a file or directory on your DOS file system, the permissions may have been set incorrectly. See your system administrator. If you are the system administrator, refer to "INTERACTIVE UNIX Operating System Maintenance Procedures" in the *INTERACTIVE UNIX Operating System Guide* for more information about permissions.

USING DOSSETTE

Device Specifiers

Like DOS, dossette recognizes certain device specifiers. For example, the specifier for the first diskette drive is a:, the specifier for the second diskette drive is b:, and the specifier for the DOS partition on the first fixed disk is c:. If you attempt to access a diskette or fixed disk partition that is not in DOS format while using dossette, an error message will display. When dossette is initially invoked, the current device is always set to a:, but it can be changed in the usual DOS fashion by entering a different device specifier, followed by **ENTER**.

DOS File Names

The format for a DOS file name includes an optional device specifier, an optional path name, and the name of the file. If the device specifier is omitted, the current device is assumed. If no path name is specified, the current directory on the specified device is assumed. The components of a path name are each separated by a slash (/). (The backslash character is not valid in dossette.) For example, the file name temp indicates the file temp in the current directory on the current DOS device; the file name b:/util/temp indicates the file name temp in the directory util in a DOS file system on the second diskette drive.

Interactive Commands

When the dossette command is typed at the prompt, dossette is invoked in interactive mode. In this mode, commands that are similar to DOS commands are read from standard input, and each line is executed as it is read. dossette prompts the user for input, as necessary. The program mimics DOS in issuing a prompt at the beginning of each line to indicate the current device, for example, A >, B >, C >. To invoke dossette interactively, type dossette at the shell prompt:

\$ dossette

A>

dossette is now ready to receive any of the following commands:

	INTERACTIVE UNIX Operating System Primer – Version 3.0
dir	Lists DOS directory information.
type	Prints a DOS ASCII file on the terminal screen.
сору	Copies a DOS file to a new DOS file name. You may also copy a DOS file to a DOS directory.
rename	Changes the name of a DOS file.
erase, del	Deletes a DOS file.
mkdir, md	Creates a DOS directory.
rmdir, rd	Removes a DOS directory.
format	Physically formats a DOS diskette. This com- mand does not format a fixed disk partition.
get	Copies a DOS file or files to a UNIX System file system and changes the file or files to UNIX System format.
put	Copies a UNIX System file or files to a DOS file system and changes the file or files to DOS format.
cd	Changes or displays the DOS working directory.
chloc	Changes the INTERACTIVE UNIX System working directory.
a:	Changes the current DOS device to drive A, which corresponds to the first diskette drive.
b:	Changes the current DOS device to drive B, which corresponds to the second diskette drive.
c: q:	Changes the current DOS device to the fixed disk partition corresponding to the device specifiers c: through q:.
help	Displays a list of available dossette com- mands on the screen.
q	Exits dossette.

62

The following examples illustrate how to use the dossette commands interactively.

The get command allows you to copy a DOS file into the INTERACTIVE UNIX System partition and converts the DOS control characters to UNIX System format:

```
get b:/util/tmp /src/unix.tmp
```

In this example, the DOS tmp file, located in the util directory on the second diskette drive, is copied to the UNIX System file, unix.tmp, in the UNIX System src directory. The file is converted to UNIX System format. Once the file is converted in this way, it can be edited using a UNIX System editor.

The put command allows you to copy a UNIX System file back to the DOS partition or diskette and converts the file to DOS format:

put /src/unix.tmp b:/util/dos.new

In this example, the unix.tmp file, located in the src directory, is copied to the DOS file, dos.new, in the DOS util directory on the second diskette drive. The file is converted to DOS format.

To exit dossette, type q at the prompt.

Batch Mode

The dossette command group is also available for use in *batch* (noninteractive) mode so that you can use the dossette commands in a shell script. In this mode, the dossette command line consists of the invoking command and its arguments, if any. The dossette batch commands are prefixed by dos; they operate in the same way as the interactive dossette commands described previously. The dossette commands available in batch mode are: dosdir, dostype, doscopy, dosrename, dosmkdir, dosrmdir, dosformat, dosget, and dosput.

This example illustrates how to use the dosget batch command. Note that the command and its arguments are typed at the shell prompt:

```
$ dosget b:/util/tmp /src/unix.tmp
```

In this example, the DOS tmp file, located in the util directory on the second diskette drive, is copied to the UNIX System file, unix.tmp, in the INTERACTIVE UNIX System src directory. The file is converted to UNIX System format.

.
GLOSSARY

absolute path name See full path name.

append

To add text to the end of an existing file.

argument

A string of text that accompanies a command and gives the computer additional information to modify the result of the command.

background

Not in the foreground, i.e., not interfering with current work on the terminal. A program that is executing in the background allows the user to continue to issue commands and interact with the computer system. To execute a program in the background, type an ampersand (δ) at the end of the command.

batch mode

A dossette interface that permits commands to be invoked noninteractively in shell scripts.

boot

To load an operating system or a standalone program into memory and execute it.

Bourne shell

The Bourne shell is considered the standard UNIX System shell and is available on UNIX System V.3. It was written at Bell Laboratories and released by AT&T (now USL).

case sensitive

Distinguishes between uppercase and lowercase.

command

An instruction the user gives to the computer. The command is interpreted by the user interface, which instructs the computer to run the program that will perform the task requested by the command. See also *argument* and *option*. command interpreter

A command interpreter passes the commands you enter to the operating system for processing and delivers the results to you. See also *shell*.

command line

The complete instruction the user gives to the computer, including the command name, options, arguments, and pipes.

console

The terminal directly attached to the computer unit.

C shell

A UNIX System shell written and released by the University of California at Berkeley. It has gained widespread popularity, particularly with programmers.

current working directory

The directory in which you are located. Its path name is returned when you use the pwd command.

cursor-positioning keys

The arrow keys on your keyboard that are usually used to move the cursor when editing text.

default

The alternative chosen by the system when no choice is specified by the user.

device-specifier

An alphabetic character followed immediately by a colon, which is used under DOS and with dossette to indicate a particular diskette drive or fixed disk partition. The device specifier b: usually indicates the second diskette drive.

directory

A special type of file that contains other files and/or directories. A typical directory contains related documents, such as memoranda or monthly sales reports.

directory files

See directory.

editor

A utility or program written to facilitate the modification and manipulation of text files.

error message

A message from the operating system that appears on your screen in response to a problem the computer has encountered with a command.

execute permission

The third permission in each set of file or directory permissions. Execute permission allows a user to execute a file or search a directory.

file

A document or a collection of information stored on the computer. For example, a file could be a list of phone numbers, a memorandum, or a report.

file access permissions

See permissions.

file system

A collection of individual files and directories that are stored on a portion of a disk.

filters

Programs that accept their input from one source, such as the standard input, perform their appointed task on the data, and then write their results to the standard output without changing the input file in any way.

flag

An option to a command. See option.

full path name

The full path name of a file completely describes the location of the file in the system. It is the sequence of directories from the root directory to the file or directory you wish to reference. It consists of a slash (/), followed by one or more directory and file names, separated by slashes.

full-screen editor

A text editor that shows the changes you are making to a file on the screen as you make them. group

A group is a collection of users. Permission for a group refers to the second set of three permissions for a file or directory. These apply to members of the owner's group only.

hardware

The physical components of a computer. Examples include the keyboard, the screen (sometimes called the display or the monitor), and the printer.

hierarchical file system

A directory structure that is arranged in a ranked series, with a single master directory at the top level and additional levels of directories or files defined beneath it.

home directory

The directory that contains the "master list" or index of the information you are storing on the computer. Most systems automatically place you in your home directory when you log in.

interactive

To carry on a dialogue with the computer.

I/O redirection

The capability of specifying the standard input and output at the time of executing a command.

kernel

That part of the UNIX Operating System that performs the system management aspects.

line editor

A text editor that requires that you explicitly specify the line or lines you want to edit and does not show the changes you make to your file as they occur. A line editor is useful if you are using a hard copy terminal, i.e, one where you do not have a screen.

log in

To type your login name and password onto your computer or terminal, indicating that you are ready to gain access to your information. login account

The information stored in a computer that provides authorization for a person to use that computer's resources. The computer's system administrator usually sets up login accounts.

log out

To terminate your access to the system. On most systems, this is accomplished by holding down the **CTRL** key while simultaneously typing d.

manual entry

A technical description and summary of use for UNIX System commands, system calls, subroutines, file formats, miscellaneous facilities, and special files found in the UNIX System reference manuals.

mount

A system administration procedure used to attach a file system to other directories of the main system. A file system must be mounted in order to be accessible to users.

multi-tasking

Capable of running many different processes (programs) at the same time.

multi-user

Capable of supporting more than one user at a time. On a multi-user computer system, each user has his or her own terminal plugged into the computer, and all can share its data and resources at the same time.

octal

The numbering system of the base 8 that uses the numbers 0, 1, 2, 3, 4, 5, 6, and 7.

operating system

The operating system is part of the system software. It is a collection of instructions written in some machine or programming language that tells the computer how to manage its operations, process and execute the user's requests, and run application software. option

An optional argument that is available to modify the results of a specific command. Options are usually preceded by a dash (-).

other

The third set of three permissions for a file or directory, which applies to everyone on the system who is neither the owner nor in the owner's group.

overwrite

To perform an operation on a file that deletes its contents and replaces it with the output of the operation. For example, if you cat a file and use the name of an already existing file as its destination, the contents of the original file is replaced with the contents of the new file.

owner

The user who creates a file and has control over the file's permissions.

parent directory

The directory immediately above the one in which you are located.

path name

The sequence of directory names and (optionally) a file name, separated by slashes, that describes the location of a file or directory on a UNIX System. There are two types of path names, the full path name and the relative path name. The full path name consists of the sequence of directories from the root directory to the file or directory you wish to reference. The relative path name omits the root directory and directory names up to the current directory.

pattern matching character

A wildcard character. A wildcard character is used to match a character or a string of characters in a file or directory name. It is another type of shortcut.

permissions

Permissions determine who can read, write, or execute a file or directory. They are indicated by the letters r, w, and x obtained when you list the contents of a directory using the long option.

pipeline

To take the output of one program and direct it to be the input to another program.

pipes

Connections between two or more UNIX System commands, indicated by a vertical bar symbol (1).

program

A set of instructions for a specific set of tasks, written in a machine or programming language, that tells the computer how to perform the tasks.

prompt

A symbol that displays on the screen to indicate that the system is ready to receive your commands. You may execute a command or run an application when the prompt is displayed.

protection mode

The permissions on a file or directory, which determine how it is "protected" from the owner, group, and others. See also *permissions*.

read permission

The first permission in each set of file or directory permissions. Read permission allows a user to view the contents of a file or directory.

redirect

To change the destination of the output or the input of a command.

relative path name

The path name of a file or directory, omitting the root directory and directory names up to the current directory.

root directory

The top-level directory in a UNIX System, designated by a slash (/). All other directories in the system connect directly or indirectly to the root directory.

shell

That part of the UNIX System that interacts with the user. It is also called a command interpreter or user interface. The two major ones in use are the Bourne shell and the C shell. The shell prompts you for commands, "interprets" your commands for the computer, and sees that it carries out the task you have requested.

shell program

See shell script.

shell prompt

The computer symbol that appears on your screen to indicate that the shell is ready to receive your commands. You may execute a command or run an application as soon as you see it.

shell script

A simple collection of shell commands normally executed on the command line, or a program that uses programming logic, variable assignment, and argument processing to perform complex tasks. Shell scripts are usually created by the user to perform frequently needed complex tasks.

single-user

Capable of supporting only one user at a time. On a single-user computer operating system, no one else can simultaneously share the computer's data or resources. Most small personal computers are single-user systems.

software

The instructions that make a computer perform its functions. Software is divided into two main groups: application and system. Application software performs specific tasks, such as word processing, spreadsheets, educational programs, and games. System software includes operating systems that tell the computer how to run application software.

standard input

Information coming from the keyboard, unless otherwise specified by the user. The user can specify that information come from a file, a device, or a pipe as well. standard output

The destination of a program's data, considered to be the terminal screen, unless otherwise specified by the user. The user can specify that information be written to a file, a device, or a pipe as well.

string

A series of characters surrounded by spaces.

system software

System software is composed of programs and utilities that manage the computer's resources and run application software. See *operating system*.

unmount

A system administration procedure used to detach a mounted file system from the main system and make it inaccessible to users.

user interface

The command interpreter, or that part of the operating system with which the user interacts.

virtual terminal

A feature that allows you to log in several times simultaneously on a console terminal and switch back and forth between the login sessions. Processes continue to run in the background even while out of view.

wildcard

A wildcard character is used to match a character or a string of characters in a file or directory name. It is a type of shortcut.

write permission

The second permission in each set of file or directory permissions. Write permission allows a user to modify (edit) the contents of a file or create and delete files in a directory.

.

System Administration for New Users of the INTERACTIVE UNIX* Operating System

1. INTRODUCTION

This document discusses some of the most basic procedures required to keep your INTERACTIVE UNIX Operating System running smoothly and provides tutorial information for performing some of those fundamental system administration tasks. It is intended for people who are responsible for running an INTERACTIVE UNIX System who have little or no experience with any UNIX-based operating system. It does *not* provide complete instructions for all of the system management procedures required to maintain the operating system. It supplements the technical information found in the *INTERACTIVE UNIX System User's/System Administrator's Reference Manual* and the "INTERACTIVE UNIX Operating System Maintenance Procedures" in the *INTERACTIVE UNIX Operating System Guide*, which together provide more complete and detailed technical information on all aspects of installing, configuring, and maintaining an INTERACTIVE UNIX System.

1.1 Before You Begin

Before you attempt any of the procedures outlined in this document, you must read and understand the material in the "INTERACTIVE UNIX Operating System Primer." You must also be familiar with a text editor if your particular hardware and software configuration requires you to tailor some of the standard configuration files. Refer to the "Documentation Roadmap" in the *INTERACTIVE UNIX Operating System Guide* to determine where to obtain additional information about text editors available for your system or additional information about UNIX-based systems, including the INTERACTIVE UNIX System. You may also need to refer to the "INTERACTIVE UNIX Operating System Maintenance Procedures" in the *INTERACTIVE UNIX Operating System Guide* or to any additional documentation supplied by your vendor to completely tailor your system.

Manual entries are referenced in this document using the form entryname(n), where entryname is the name of the entry and n is the number of the section. All entries are in the *INTERACTIVE*

UNIX System User's/System Administrator's Reference Manual unless explicitly stated otherwise.

1.2 Overview of This Document

This document is divided into 14 major sections:

1. INTRODUCTION

This section provides a general overview of this document.

2. WHAT IS A SYSTEM ADMINISTRATOR?

This section explains the basic duties of the individual responsible for installing and maintaining a system.

- 3. SHUTTING DOWN AND BRINGING UP THE SYSTEM This section explains how to boot the system, how to shut it down gracefully, and how to reboot the system.
- 4. SPECIAL USERS ON THE INTERACTIVE UNIX OPERATING SYSTEM This section lists the privileged users and tells how to access those accounts.
- 5. THE SYSTEM ADMINISTRATION PROGRAM This section describes the system administration program available with this system and how to access its different levels using the sysadm command.
- 6. MANAGING USER ACCOUNTS

This section describes the attributes of each user login and explains how to use the sysadm command to add, change, or delete user accounts.

7. SETTING UP YOUR PRINTER

This section describes how to configure your software to add a printer to your system using the sysadm command.

8. TAILORING THE ENVIRONMENT

This section describes the environment variables, the most commonly configured system files, and the cron program. It also explains how to set the date and time and change the message of the day. 9. UNDERSTANDING INTERACTIVE UNIX SYSTEM FILE SYSTEMS

This section explains the structure of INTERACTIVE UNIX System file systems and describes the conventions used to name file systems and devices.

- 10. USING UTILITIES WITH THE DISKETTE DRIVE This section explains how to format diskettes and how to copy files to diskettes.
- 11. FILE SYSTEM MAINTENANCE

This section explains how to create and maintain INTERACTIVE UNIX System file systems.

- 12. BACKING UP FILES This section describes how to back up files.
- **13. MANAGING DEVICES**

This section gives a brief explanation of devices, device drivers, the kernel, and the High Performance Device Driver.

14. ADMINISTERING SYSTEM SECURITY

This section discusses general requirements for system security and basic precautions.

GLOSSARY

sysadm Menu Bypass Commands

2. WHAT IS A SYSTEM ADMINISTRATOR?

The system administrator is the individual responsible for installing, administering, and maintaining your INTERACTIVE UNIX Operating System. If the INTERACTIVE UNIX System is installed on a personal computer, you will probably act as the system administrator. If your personal computer is part of a larger network of computers, a system administrator from the computer operations department of your company may be assigned to help you keep your system running smoothly. This document assumes that you will be responsible for basic system administration tasks.

A system administrator can have many responsibilities, but there are several fundamental tasks that must be performed after your system is initially installed. You will be responsible for:

- Managing user accounts
- Tailoring the system
- Installing new software packages
- Installing new hardware devices and their associated drivers
- Maintaining file systems
- Performing routine maintenance procedures, such as backing up files

You should use the *console terminal* to perform all system administration tasks. The console terminal is comprised of the screen and keyboard directly attached to the Central Processing Unit (CPU). It is important for the system administrator to use the console terminal since most error messages generated by the system are displayed on the console terminal screen.

The following sections provide you with a conceptual overview of each of the topics listed above. Where appropriate, tutorial instructions are included. You may also want to refer to the "INTER-ACTIVE UNIX Operating System Maintenance Procedures" for more information when you are using your computer.

3. SHUTTING DOWN AND BRINGING UP THE SYSTEM

The procedures for shutting down and bringing up the system are already familiar to you if you have followed the installation instructions outlined in the "INTERACTIVE UNIX Operating System Installation Instructions."

3.1 Shutting Down the System

When you are ready to turn off your computer, you must arrange to have the computer complete all of the tasks that are currently running. This is accomplished with a system maintenance procedure called shutdown. The shutdown program gracefully terminates all tasks that are currently executing before it halts the system. When shutdown has finished, you may safely turn off the computer. If you do not run the shutdown program, you may lose data that is stored on your system and cause damage to your file system, even if no one is currently logged in.

The shutdown program can be run in two ways:

- 1. Use the powerdown administrative login.
- 2. Execute the shutdown command.

3.2 Using the powerdown Administrative Login

When you are ready to turn your computer off, you may use the powerdown administrative login to bring the system down.

- 1. Log out of your ordinary user account.
- 2. Log in to the system with the powerdown user ID.
 - You must remember the powerdown password you set during installation, or use the passwd command to set a password for the powerdown login.
- 3. Once you have successfully logged in to the system using the powerdown login, the system automatically executes the shutdown program. The system displays a screen similar to this:

```
login: powerdown
Password:
UNIX System V/386 Release 3.2
Copyright (C) 1984, 1986, 1987, 1988 AT&T
Copyright (C) 1987, 1988 Microsoft Corporation
All Rights Reserved
Login last used: Mon Sep 19 12:24:32 1988
/ : Disk Space: 4.86 MB of 26.96 MB available (18.06%)
Total Disk Space: 4.86 MB of 26.96 MB available (18.06%)
Once started, a powerdown CANNOT BE STOPPED.
Do you want to start an express powerdown [y, n, ?, q]
```

4. To bring the system down, type y. The system responds:

Shutdown started. Wed Jun 3 17:31:44 PDT 1988

Broadcast message from root (console) on bud Wed Jun 3 17:31:44 THE SYSTEM IS BEING SHUT DOWN!!! Log off now or risk your files being damaged.

```
INIT: New run level 0
The system is coming down, please wait.
System services are now being stopped.
cron aborted: SIGTERM
I SIGTERM Wed Jun 3 17:31:44 1988
I ******* CRON ABORTED ******* Wed Jun 3 17:31:44 1988
Print services stopped.
Stopping Network Processes...
```

The system is down Press any key to reboot.

5. When the Press any key to reboot message appears, the computer may be safely turned off.

3.3 Using the shutdown Command

To execute the shutdown command manually, you must log in to the system as the root user on the console terminal and you must be in the root directory.

The root user is the most privileged user on the system; this login ID is commonly known as the *superuser*. There are no restrictions imposed upon root, which means that the person logged in to the system with the root ID can access, modify, and delete every file and process on the system. The root login is discussed in more detail in section 4.1.1. When you are logged in as root, your login prompt is a pound sign (#). To execute the shutdown command manually:

1. Log in as root. Your screen will look similar to this:

```
login: root
Password:
UNIX System V/386 Release 3.2
Copyright (C) 1984, 1986, 1987, 1988 AT&T
Copyright (c) 1987, 1988 Microsoft Corporation
All Rights Reserved
Login last used: Mon Sep 19 12:24:32 1988
#
```

The # prompt indicates that the system is ready for you to type in a command.

2. Move to the root directory by typing:

cd /

Refer to the "INTERACTIVE UNIX Operating System Primer" for more information about directories.

3. Run the shutdown program by typing:

shutdown

The system automatically generates a message on every terminal currently in use to warn users that the system is being shut down. The message will look similar to this:

Shutdown started. Wed Jun 3 17:31:44 PDT 1988 Broadcast message from root (console) on bud Wed Jun 3 17:31:44 THE SYSTEM IS BEING SHUT DOWN!!! Log off now or risk your files being damaged.

The system gives users 1 minute to exit editors and save files. After this 1 minute warning period is over, the shutdown program prompts you for confirmation that you want to continue. Your screen will look similar to this:

Do you want to continue (y or n):

4. Type y if you want to continue shutting down the system, n if you want to stop. If you type y, the system is then shut down. You may press any key to reboot the system or turn off the power to the computer at this point. If you type n, the system issues the following message to all users currently logged on to the system:

> Broadcast message from root (console) on bud Wed Jun 3 17:31:44 False Alarm: The system will not be brought down.

The system then aborts the shutdown and displays the following message on the console:

Shutdown aborted.

5. If you wish to give users a longer warning period before the system goes down, run the shutdown program using the -g option:

shutdown -gtime-y

In this example, *time* represents the number of seconds the system will wait before it goes down. It is a good idea to allow at least 2 minutes (120 seconds) to elapse before the system is brought down. Using the -y option causes the shutdown procedure to continue directly without prompting you for permission to proceed.

After the warning period, the system automatically runs shutdown. Your screen will look similar to the one generated by the powerdown procedure:

Shutdown started. Wed Jun 3 17:31:44 PDT 1988 Broadcast message from root (console) on bud Wed Jun 3 17:31:44 THE SYSTEM IS BEING SHUT DOWNIII Log off now or risk your files being damaged. INIT: New run level 0 The system is coming down, please wait. System services are now being stopped. cron aborted: SIGTERM ! SIGTERM Wed Jun 3 17:31:44 1988 ! ****** CRON ABORTED ****** Wed Jun 3 17:31:44 1988 Print services stopped. Stopping Network Processes... The system is down

Press any key to reboot.

Be sure that you do not attempt to power down or reboot the system until the above completion message is displayed.

See *shutdown*(1) for more information.

3.4 Bringing Up the System

To bring up or *reboot* the system (as it is frequently called), use this procedure:

1. First check the diskette drives and remove any diskettes there. If the system finds a diskette when it is first turned on, it will attempt to boot from it. If it does not find a diskette, it will boot from the fixed disk when the power is turned on.

- 2. If your computer is still turned on, either turn it off and turn on the power again, or press any key to reboot.
- 3. If your system power is turned off, turn on the power. The INTERACTIVE UNIX Operating System automatically boots.

When it reboots, the system does the following:

- Runs internal diagnostic programs to check your hardware
- Displays memory and copyright information and the message:

Booting the INTERACTIVE UNIX Operating System...

- Determines if the system was shut down properly
- Checks the file systems for inconsistencies and attempts to make any necessary repairs
- Starts various system processes, such as the line printer scheduler

If your system has crashed for some reason, the system may ask if you want to save a *system dump*. A system dump is used by experienced system administrators to obtain detailed information about the state of the system when it crashed. Under most circumstances, you will want to answer n to this prompt.

4. SPECIAL USERS ON THE INTERACTIVE UNIX OPERATING SYSTEM

There are three types of login accounts on an INTERACTIVE UNIX Operating System: an *ordinary* login account, a *system* login account, and an *administrative* login account. A login account gives access to the system.

Ordinary logins include a login ID, a password, and an area of the file system "assigned" to the user, called a *home directory*. Every user on the system (including the system administrator) uses an ordinary login account to perform most tasks. These accounts are used to store data and run application programs, such as an accounting or word processing program. Ordinary logins may have restricted access to other user login accounts and to system administration functions. The procedure for creating an ordinary user account is described in section 6.4.

System logins are used to perform system administration tasks that require privileged access to the restricted files and directories on the system. You typically use a system login when you need to perform system maintenance tasks for the operating system or hardware facilities on your system. These logins should be used with great care. System login accounts exist in the INTERACTIVE UNIX System.

Administrative logins are used to give ordinary users restricted access to system management functions that must be performed frequently. For example, there are administrative logins available for adding new users or shutting down the system. Administrative login accounts exist in the INTERACTIVE UNIX System.

The system is delivered with all system and administrative accounts, *except* the root account, locked. The system administrator should *immediately* set a password for the root account and should then use the root account to change the password for all the other system and administrative accounts.

4.1 System Login Accounts

When you initially installed your system, several system logins were automatically created for you. The two most important system logins are root and bin. They are used to perform most privileged system administration functions. Other system logins are available to monitor and manage continuously running processes, to run the program that updates the fixed disk, and to manage networking operations.

All system logins should be used only when it is absolutely necessar v.

System logins have few restrictions imposed upon them by the operating system, which means that they can cause serious damage to your system when used incorrectly. A password for each of the system logins, except root, must be assigned before that login can be used. (See section 4.6.1 in the "INTERACTIVE UNIX Operating System Installation Instructions" for more information about assigning system passwords.) Passwords for system logins should only be given to the individual(s) designated as the system administrator(s) for your system. Each system login is described below.

4.1.1 The root Login

The most important INTERACTIVE UNIX System login belongs to the root user. This login account, also known as the superuser, is the most privileged and powerful account on the system. There are no restrictions imposed upon root, which means that individuals who have access to the root login also have access to every other account on the system. The root user can access, modify, and delete every file and process on the system.

It is very important to:

- Assign a password to the root account.
- Change the root password frequently.
- Distribute it only to only a few individuals who are responsible for system administration tasks.
- Use it only for system administration tasks.
- Be very careful when using it.

You must be at the console terminal to log in to the system as root. This is an additional safeguard that helps limit the use of the root login. You will use the root login to configure the system kernel, add new peripheral devices (like printers), and mount or unmount file systems.

Once you have logged in to the system using the root login, the system displays the pound sign (#) as the prompt.

4.1.2 The bin Login

The bin system login owns most of the command files and directories on the system, including all of the special files used to access fixed disks and diskettes. The bin login account has the same privileges as an ordinary user, but also owns the directories /bin, /usr/bin, /lib, and /etc. You must log in as bin (or be logged in as root) to install new programs and libraries in these directories. You can use the bin login to install new software or to modify the files and directories owned by bin. This login is also used to limit user access to files and directories that can affect the entire system.

4.1.3 Other System Logins

The system automatically provides several other system logins: daemon, sync, uucp, and nuucp. You should assign a password to these accounts, but you should never need to log in using daemon, sync, or nuucp. These system logins and their functions are described below.

- daemon A daemon is a program that executes continuously on the system. For example, the program responsible for queuing print jobs is a daemon. This login is provided because certain programs on the system must be owned by daemon.
- sync This login executes the sync program, which updates the fixed disk every 10 seconds with the work currently in progress.
- uucp This login owns the files in the directory /usr/lib/uucp. It may occasionally be necessary to log in as uucp to change these files, which are used in the UNIX-to-UNIX-copy file transfer programs.
- nucp This login is used by remote machines to log in to your computer system and to initiate UNIX-to-UNIX file transfers.

4.2 Administrative Login Accounts

There are a number of tasks that require privileged access to the system. Because the root login is so powerful, it is not a good

idea to use it to perform all of the administrative tasks that are required to keep the system running properly. Instead, several administrative logins are provided with your system to facilitate system maintenance. As with all sensitive login accounts, you must set a password for each login and limit the password's distribution. The administrative login accounts are described below.

sysadm This login account gives you direct access to the sysadm facility. sysadm is a menu-driven facility that may be used to perform most system administration procedures. It is described in section 5.

powerdown

The powerdown login may be used to shut down the system. All the processes running on an INTERACTIVE UNIX System must be gracefully terminated before the computer is turned off, in order to prevent serious damage to the file system or loss of data. The powerdown login is provided to facilitate this process. Refer to section 4.6.1 or the "INTER-ACTIVE UNIX Operating System Installation Instructions" for more information.

```
checkfsys
makefsys
mountfsys
umountfsys
```

These four logins may be used to directly access the file system maintenance options that are available as part of the sysadm login and *utility*. (A utility is a program, usually from a set of programs, that represents a specific application available with your computer.) You can use the sysadm login to access these options as well. Refer to sections 5 and 11 for more information.

4.3 Accessing Other User Accounts (the su Command)

If you know another user's login name and password, you can use the su command to temporarily log in to that user's account and gain access to protected files, directories, and programs. This can be very useful, for example, if you need to temporarily access either a system or an administrative login without logging out. To access another user account without logging out, follow these instructions: 1. Use the su command to acquire root's privileges without logging out. (Note that although you have to be at the console terminal to *log in* as root, you do not have to be at the console terminal to su to root.) Type:

\$ su - root

and press **ENTER**.

- 2. If a password is assigned to that account, the system asks for a Password:. Enter the correct password and press **ENTER**.
- 3. The system responds with the # prompt. You now have all the privileges of the root user, and you are placed in root's home directory, /.
- 4. Type exit or press **CTRL d** simultaneously to exit the root account and return to your normal user account.

This same procedure can be used to access any user account for which you know the correct login name and password.

5. THE SYSTEM ADMINISTRATION PROGRAM

5.1 Introduction

The system administration program is a standard feature of the INTERACTIVE UNIX Operating System. It is a menu-driven interface that makes it easy to perform commonly required system administration tasks and is designed to be as self-explanatory as possible. The sysadm program makes use of the INTERACTIVE Character User Interface (CUI). If you've never used sysadm before, you should read, either in this guide or on-line, the short summary of how to get help and how to use the menus and forms to perform tasks.

This section provides an overview of the system administration menus and the purpose of each. The use of specific system administration procedures is discussed in the appropriate task-related sections of this document and in the "INTERACTIVE UNIX Operating System Maintenance Procedures."

This document does not attempt to describe every possible maintenance procedure available through the system administration menu. As you become familiar with this interface, you may wish to explore the usage of some of the menu items that you see that are not described here by simply trying them out. The system prompts you step-by-step through the procedures.

sysadm is both a login account and a utility program. This means that you may access sysadm either by logging in to the system with the sysadm login or by typing the sysadm command when you are already logged in to the system. If you log in as sysadm, the system displays a screen similar to this:

```
login: sysadm
Password:
```

You must know the sysadm password to use this login. If you are already logged in, type sysadm at the shell prompt:

\$ sysadm

The system will prompt for a password.

5.2 The sysdemo Login

The sysdemo login account is a tutorial login that provides the full functionality of the sysadm program without actually performing the functions. This provides a safe way to learn to use the system. The sysadm forms are brought up on the screen and the hypertext help is available, just as they would be under the sysadm account. If you would like to explore the system using the sysdemo login, you must know the sysdemo password. Your screen will look similar to this:

```
login: sysdemo
Password:
```

If you are already logged in, type sysdemo at the prompt:

```
$ sysdemo
```

5.3 Using the CUI Help Facility

You can press $\boxed{F1}$ for on-line help at any time. If context-specific help is available, it appears. Pressing $\boxed{F1}$ a second time accesses the general Help Index. If no context-specific help is available, the Help Index appears immediately. Use the up and down arrow keys or $\boxed{PAGE-UP}$ and $\boxed{PAGE-DOWN}$ to scroll through the Help Index. Press \boxed{ENTER} to select a topic.

There are also HELP buttons at the bottom of many forms. Use **TAB** or **BACK-TAB** to move to the HELP button, and press **ENTER** to obtain general help on the form you are viewing. Some help topics have more than one page. To move from page to page of each help topic, use **PAGE-UP** or **PAGE-DOWN**. You can exit from the help system at any time by pressing **ESC**. The following table summarizes how to use the help system:

Using the Help System						
ACTION	KEY					
Display context-specific help Display the Help Index	<f1> <f1> when already in the Help System <f1> <f1> when you are <i>not</i> in the help system</f1></f1></f1></f1>					
Scroll through Help Index Page through Help Index Select a Help Index topic Move to the HELP button Activate the HELP button Page through help topics Exit the help system	up and down arrow keys <page-up> or <page-down> <enter> <tab> or <back-tab> <enter> <page-up> or <page-down> <esc></esc></page-down></page-up></enter></back-tab></tab></enter></page-down></page-up>					

5.3.1 Hypertext

The help in this program is a hypertext system. The system provides one or more pages of help on a number of topics. Topics are connected to each other by means of links. Links are words that appear on-line in **bold** text. Three standard links appear at the bottom of each help window:

Exit	Go Back	Index
Exit Go Back		 always takes you out of the help system. always takes you to the previous topic, if one exists
Ind	ex	- always takes you to the Help Index.

Links in the text provide a path to additional information about a topic that you may or may not want to see. Press **TAB** or **BACK-TAB** to move from link to link. When the one you want is highlighted (active), press **ENTER** to follow it.

5.3.2 Links

When you follow a link, a new topic appears. If there is more than one page in the topic, use $\boxed{PAGE-UP}$ or $\boxed{PAGE-DOWN}$ to move through it. To return to the previous topic, press \boxed{TAB} or **BACK-TAB** to move to Go Back at the bottom of the help window and press **ENTER**. You can follow any number of links through this system. Using Go Back will retrace your steps exactly to the original point at which you entered the system.

5.4 Using INTERACTIVE CUI Menus and Forms

The INTERACTIVE CUI System is designed to make administration of the INTERACTIVE UNIX Operating System as easy as possible. Its major components are the bar menu at the top of your screen, pull-down menus, and forms.

5.4.1 The Bar Menu

Use the left and right arrow keys \leftarrow \rightarrow to move from title to title of the bar menu. Press $\boxed{F1}$ for on-line help on the bar menu titles. Press \boxed{ENTER} to pull down a menu. To exit from the bar menu and return to the system prompt, move to Quit and press \boxed{ENTER} .

5.4.2 Pull-Down Menus

Use the up and down arrow keys $\boxed{1}$ $\boxed{1}$ to move from option to option, or type the first letter(s) of an option name. If there is an arrow (->) following the option, another menu appears when you press **ENTER**. If there is no arrow, a form appears when you press **ENTER**. Press **F1** for on-line help on the menu items. To exit from a pull-down menu, move to Quit (or type q) and press **ENTER**, or simply press **ESC**.

5.4.3 Forms

Forms are used to display or gather information needed to perform the task you selected from a pull-down menu. Forms contain several different kinds of fields. Some fields are used only to display information; you cannot press **TAB** or **BACK-TAB** to move to them or change them. Other fields allow you to edit them by making choices or typing information. Help is available for fields that you can edit. Press **F1** for on-line help on these fields. To move from field to field and button to button, press **TAB** or **BACK-TAB**.

All forms have at least one button in a box at the bottom of the form. Most forms have these buttons:
ок	CANCEL	HELP
ОК		confirms that you are satisfied with the informa- tion on the form and want your changes to take effect.
CAN	CEL	exits from the form without any changes taking effect.
HEL	Р	provides help for the form.

To activate a button, press **TAB** or **BACK-TAB** to move to it and press **ENTER**.

5.4.4 Fields

Forms in this system contain a number of different kinds of fields. Some fields are lists that you can scroll through using the up and down arrow keys. Some lists are always visible, while others require you to press the spacebar to pop them up. Press **ENTER** while an item is highlighted to select it from the list. Help is available for fields that you can edit. Press **F1** for on-line help on these fields.

- Fields within angle brackets < > allow you to use the spacebar to cycle through the choices for that field or to press the spacebar to pop up a list of values. Use the up and down arrow keys to scroll through the items in a list. Press ENTER to select one.
- [] Fields within square brackets [] are check boxes. Press the spacebar to "check" the box (an x appears). You can press the spacebar to toggle the x in or out of a field.
- () Fields within parentheses () are radio buttons. They usually occur in sets where a choice must be made between two or more mutually exclusive options. Press the spacebar to turn the radio button "on" and an asterisk (*) appears. If you turn on one radio button, the other choices automatically go "off."

For a summary of the key strokes used in this system, see Using Bar Menus, Using Pull-Down Menus, Using Forms, and Special Keys on your Quick Reference Card.

5.5 Bar Menu Options

When you type the sysadm command, the system administration bar menu is displayed at the top of the screen. If you set a password for the sysadm login when you installed the system, you are prompted for a password as usual. The system displays:

<u>Disk</u> Manage	File disks and	Machine diskettes	Software	User	Help	Quit
		513	IEM RUMINIS.			

Each title on the bar menu represents a category of tasks that are usually performed by the system administrator. When you select an option, the system displays a menu that lists the tasks that are specific to that option. When you select an option from a menu, the system either provides a form with step-by-step procedures for performing the specified task or displays another pull-down menu.

The following menus are available:

• Disk Menu

The Disk menu is used for tasks related to your fixed disks and diskettes. The tasks you can perform using the options on this menu include copying diskettes, checking the integrity of diskette-based file systems, deleting data from diskettes, and making new diskettes accessible to the system. You may also use the options on this menu to perform similar tasks on a fixed disk, to inform the system about defects on your fixed disk, or to determine the current partition configuration of your fixed disk. Refer to section 11, "FILE SYSTEM MAINTENANCE," for information about using the Disk menu and to the "INTER-ACTIVE UNIX Operating System Maintenance Procedures" for information about manipulating file systems on your fixed disk.

• File Menu

The File menu options allow you to back up, restore, configure, and monitor file systems. Use the options on this menu to back up data from your fixed disk onto a diskette or other device or transfer the data to a fixed disk.

Refer to section 12, "BACKING UP FILES," for information about using the File menu.

• Machine Menu

The Machine menu includes options to add a printer to your system and to change the number of virtual terminals available at the console terminal. Other options allow you to initialize your system the first time you install it or to change the current administrative and system passwords, date, and time. In addition, this menu has an option to configure the lines that connect your terminal, modem, or other device to the main CPU. Refer to section 7, "SETTING UP YOUR PRINTER," for information about adding a printer to your system.

• Software Menu

The Software menu options allow you to list, install, configure, and remove software packages and extensions, as well as configure the standard networking utility available for the INTERACTIVE UNIX System uucp (unix-to-unix copy).

The installation of software packages is discussed in section 6 of the "INTERACTIVE UNIX Operating System Installation Instructions." Refer to section 11, "BASIC NETWORKING ADMINISTRATION," in the "INTERACTIVE UNIX Operating System Maintenance Procedures" for more information on the installation and configuration of uucp.

• User Menu

The User menu options allow you to establish and configure user login accounts. Among other things, it can be used to list, add, and delete users and groups. This menu is described in more detail in section 6.4, "Managing User Accounts With sysadm."

5.6 Using the sysadm Menus

The following commands and conventions apply when you are using the sysadm login, sysadm command, or any sysadm menu:

- You must be at the console terminal to log in as sysadm, and you must know the sysadm password.
- Use the left and right arrow keys → to move from title to title of the bar menu. Press ENTER to pull down a menu. To exit from the bar menu and return to the system prompt, move to Quit and press ENTER.
- Use the up and down arrow keys f i to move from option to option on a pull-down menu, or type the first letter(s) of an option name. If there is an arrow (->) following the option, another menu appears when you press ENTER. If there is no arrow, a form appears when you press ENTER. To exit from a pull-down menu or return to a previous menu at any point, move to Quit (or type q) and press ENTER, or simply press ESC.
- Forms are used to display information needed to perform tasks. Forms contain several different kinds of fields. Some fields are used only to display information; you cannot **TAB** or **BACK-TAB** to them or change them. Other fields allow you to edit them by making choices or typing information. Help is available for fields that you can edit. **TAB** or **BACK-TAB** to move from field to field and button to button. All forms have at least one button in a box at the bottom of the form. To activate a button, **TAB** or **BACK-TAB** to it and press **ENTER**. Most forms have these buttons:
 - OK confirms that you are satisfied with the information on the form and want your changes, if any, to take effect.
 - CANCEL exits from the form without any changes taking effect.
 - HELP provides help for the form.

To choose a button, **TAB** or **BACK-TAB** to it and press **ENTER**.

• If you do not understand the options or what to put into a field in a form displayed by the system, press the **F1** key for on-line help at any time. If context-specific help is available, it appears. Pressing $\boxed{F1}$ a second time accesses the Help Index. This is a list of topics for which help is available. If no context-specific help is available, the Help Index appears immediately. \boxed{TAB} or $\boxed{BACK-TAB}$ to a topic and press \boxed{ENTER} to view a help screen. Use $\boxed{PAGE-UP}$ or $\boxed{PAGE-DOWN}$ for those help topics that contain more than one page.

There are also HELP buttons at the bottom of many forms. **TAB** or **BACK-TAB** to the HELP button and press **ENTER** to obtain general help on the form you are viewing. Use **PAGE-UP** or **PAGE-DOWN** for those help topics that contain more than one page. You can exit from the help system at any time by pressing **ESC**.

- To exit the sysadm program, move to the Quit option on the bar menu at the top of your screen and press **ENTER**.
- If your screen is ever obscured by extraneous text, such as console messages, type **CTRL r** to refresh it.

5.6.1 sysadm Menu Bypass

You may access a sysadm pull-down menu directly by typing sysadm, followed by the appropriate command name. For example, type:

sysadm disk

to access the sysadm Disk menu.

Each sysadm pull-down menu contains a list of options and/or other menus. You may bypass the menus and access a known option directly by typing the option name as an argument to sysadm. For example, the Diskette Management menu contains an option for formatting a disk, called Format a Diskette. You can access that option directly by typing:

sysadm fmtdisk

If you use sysadm as a login, you may also supply the sysadm options described above, such as fmtdisk, at the login prompt:

login: sysadm fmtdisk

The following table shows the command names of the sysadm menus and options. There may be fewer or additional menus and options on your system, depending on the software subsets and extensions that you have installed. This table is reproduced at the back of this document for your convenience.

Menu or Form	Command
Disk	disk
Current Disk Usage	diskuse
Diskette Management	diskettes
Copy a Diskette	cpdisk
Erase a Diskette	eradisk
Format a Diskette	fmtdisk
Verify a Diskette	verdisk
File System Management	filesys
Check a Diskette File System	chkfdfs
Create a Diskette File System	mkfdfs
Mount a Diskette File System	mntfdfs
Unmount a Diskette File System	umntfdfs
Fixed Disk Management	harddisk
Remap Disk Defects	badblks
Add a Fixed Disk to the System	addhd
Check a Fixed Disk File System	chkhdfs
Display Fixed Disk Information	lshd
Mount a Fixed Disk File System	mnthdfs
Unmount a Fixed Disk File System	umnthdfs

Menu or Form	Command
File	file
Back Up or Restore Files	backups
Back Up Selected Files	backup
Archival/Incremental Backup	fsback
Restore Files	restor
File Information	fileinfo
Owner/Group	filuse
Age	filage
Size	filsiz

Menu or Form	Command
Machine	machine
Current Disk Usage	diskuse
Modem Initialization	setmodm
Printer Management	lpmgmt
Add a Printer	addprt

List Users	lsusrs
List All Users	lsuser
List System Users	lsSuser
List Regular Users	lsUuser

6. MANAGING USER ACCOUNTS

6.1 Introduction

The INTERACTIVE UNIX Operating System requires that users log in to the system with a login name and, optionally, a password. This enables the system administrator to keep track of users on the system, control access to the system, and control system resources. All individual users should use a private login. (Other computers can use generic logins such as mail or nuucp to log in to your computer and exchange information.)

The system administrator is responsible for establishing and maintaining a login account for each user who requires access to the system. This includes adding users, aging user passwords (if desired), changing user passwords (if necessary), and removing user logins that are no longer needed. Use the sysadm command or login to establish new user accounts. sysadm provides a safe and secure way to manage new and existing user accounts.

6.2 What Is a User Login Account?

A user login account defines the user's environment, which can be very restricted or highly privileged. It is defined by a number of attributes (characteristics) that are established when a login ID is created, and it determines the security levels that are imposed upon the user, including the programs and files that are accessible.

At the simplest level, a user login consists of the following information stored in the /etc/passwd file, which defines a user's individual environment:

The name used to log in to the system. The user types this name at the login: prompt. This one to eight character string must be unique for each user; a first name, last name, initials, or some combination are typically used. It may only consist of lowercase letters and/or numbers. Uppercase letters and special symbols are not permitted.

• password mark

A mark indicating whether or not the user has a password. An x is placed in this field if there is an encrypted password entry in /etc/shadow for this user. If the user does not have an encrypted password entry in /etc/shadow, this field will be

[•] login ID

blank. The actual password is a string the user must know and type in when logging in to the system. It should be known only to the user.

• user ID

A user identification number (frequently abbreviated UID) is a unique number assigned to each login account. The system starts with a default number (for example, 100), then increments the number by one each time a new user is added to the system. This number is associated with all files and processes created by that user name. The user ID is usually unique for each user login.

• group ID

A group identification number (frequently abbreviated GID) is a number that associates a user with a group. There may be one or more groups on the system. A default group and group ID number are automatically assigned to a user. An affiliation with a group means that a user can access the files and directories that are owned by members of that group, if the group permissions on those files or directories permit it. The GID is associated with an entry in the file /etc/group.

• user name

This is the full name of the user (e.g., Joe Smith, Jane Grey, etc.). It is included because user login IDs are sometimes cryptic.

• home directory

The full path name of the directory into which the user is automatically placed after logging in. This directory belongs solely to the user, who can restrict others' access to the files and directories created there. (Only the superuser can access this directory if the user chooses to restrict all others.) The home directory must be unique for each user login.

• login program name

This is the full path name of the program the system runs each time the user logs in. This is usually the shell (/bin/sh), but it may be another program, such as a restricted shell (/bin/rsh), the C shell (/bin/csh), or an application program, such as the VP/ix* Environment.

6.3 System Files That Define the User's Environment

6.3.1 The /etc/passwd File

The /etc/passwd file identifies each user to the system. Each time you add a user to the system, an entry is added to this file. When a user attempts to log in to the system, the system checks the login ID against the list of authorized users that is stored in the file /etc/passwd. The user's password is checked against the entry for that user in /etc/shadow. If a login ID or password is missing or incorrect, the user cannot gain access to the system. If the user provides a correct login ID and password, the user is logged in to the system with access to all of the resources assigned to that login ID. A password provides an additional level of security on the system and should be set for each user account. By default, the system forces users to establish one the first time they log in, if the system administrator has not already assigned one. (To change the default, refer to login(1).)

Use the sysadm command to establish each of these fields for a new user or to change the information in these fields for an existing user account. /etc/passwd is automatically modified by sysadm each time you add, delete, or change a login account. You should never directly edit the password files themselves. Refer to section 6.4 for more information about using the sysadm utility.

6.3.2 The /etc/group File

Just as /etc/passwd defines the individual user's environment, the /etc/group file defines the environment for each system group. This file is used to establish another level of security for each login ID. Each user on the system is assigned to one or more groups. Members of a group have access to files and directories that are owned by other members of that group. The default group identity for users of the INTERACTIVE UNIX Operating System is other. Additional group identities supplied with your system are root, bin, sys, adm, mail, rje, and daemon. You may create new groups based on your use of the system. The file /etc/group contains a one-line entry with the following information for each group:

The group name

A group name is a word, number, or abbreviation that is up to eight characters in length. You typically use a name that refers to the group. For example, you may select mktg as the group name for all members of the Marketing Department or fin for the people in your Finance Department. A group name may only consist of lowercase letters and/or numbers. Uppercase letters and special symbols are not permitted.

A password

Not used.

A group ID number

This is a numeric identification that is associated with the group name. This number is the same as the GID number found in /etc/passwd.

A list of users in the group

You may include a list of user login IDs that are associated with the named group. To include a list of users in this group, separated by commas, you must edit the file directly rather than using the sysadm procedure. This entry is optional.

/etc/group is automatically modified by sysadm each time a new group is added to or deleted from the system.

6.3.3 The /etc/shadow File

Another file, /etc/shadow, is used primarily to provide tighter security. It contains the user's actual encrypted password and password aging information. Every time you log in, the system checks your password against your entry in /etc/shadow. A password provides an additional level of security on the system and should be set for each user account. Only users with access to the password for a login ID (and the superuser) can access that account. The password is never displayed on the screen. It does not appear when it is first established, when you use it to log in, or when it is changed with sysadm or the passwd command. This procedure helps to maintain a high degree of system security.

/etc/shadow is automatically modified by sysadm each time a new user is added to or deleted from the system.

6.4 Managing User Accounts With sysadm

Use sysadm to manage the facilities that govern user logins. The User menu provides many of the options you need to add, delete, or modify entries in /etc/passwd and /etc/group. If you are not an experienced system administrator, it is best to use sysadm to make changes; do not attempt to modify these files directly.

You are now familiar with the fields that are used to establish login and group IDs. The sysadm forms and help screens provide stepby-step instructions that make it clear how to modify one or more of these fields. The sysadm User menu includes several options for managing users and groups on the system. You can add a group to the system, add a user to the system, delete a group from the system, delete a user from the system, list the groups on the system, list the users on the system, modify the defaults used by the adduser command, modify a user's login, and change a group's name.

After going through the two most commonly used options presented in this section, you should have no trouble following the other available options.

6.4.1 Adding a New User

1. Log in as sysadm:

login: sysadm Password:

2. Select the User menu. Your screen will look similar to this:

Disk List users	File currently	Machine on this mac	Software hine	User	Help	Quit
		013	IER RUMINISI	List Ac Group M User Ma Quit	ctive Users Management Anagement	-> ->
<u> </u>						

Note that an arrow (->) to the right of a menu option indicates that option leads to another menu.

3. Select the User Management option, then select Add a New User. The screen will look similar to this:

Disk Add a n	File ew user to the	Machine system	Software	User	Help	Quit		
		-,	—Add a New	User				Ŧ
		Curi	rent User Pa	rameters				
	Full name:						—	ľ
	Login ID:			User ID:	668			
	Home direc	tory:						
	Login grou	p: <otl< td=""><td>ner ></td><td>Group ID:</td><td>1</td><td></td><td></td><td></td></otl<>	ner >	Group ID:	1			
	Login shel	1: <td>in/sh</td> <td>:</td> <td>></td> <td></td> <td>-></td> <td>ļ</td>	in/sh	:	>		->	ļ
	Assign pas	sword? <	(es>				i	
		OK	CANCEL	,]	HELP			
							•	
								-
								_

The Add a New User form displayed above contains these fields:

Full name

Type the full name of the user who will own this account. For example, type Robin Hood. You may not skip this field.

Login ID

The login ID is the name by which the system will identify the user. Enter an appropriate login ID for the user, for example, robin.

User ID

The User ID is the number used by the system to associate data files with a login ID. The system supplies a default user identification number (UID) in this field, automatically incrementing the last assigned number by one each time you add a new user to the system. Press **ENTER** to accept the default UID. If you wish to assign a different user ID number, you may override the default number by typing a new number over it.

Home directory

This is the directory in which the user is placed at login. The system supplies the path name for the user's home directory in this field. Press **ENTER** to accept the default path name, or type in another path name if you do not want to use the default path name.

Login group

This is the group to which the user is assigned. The system provides the name of the user's default login group in this field. To select a different login group, press the spacebar to pop up the list of available groups. Note that if you have not added any groups to your system, only other will be displayed. Your screen will look similar to this:

		Curr	Add a New	User		
	8011	Curr	ent User Pa			
				Lameters		
	Full name:	robi	n hood			
	Login ID:	robi	n	User ID:	668	
	Home directory:	/usr	/robin			
	Login group:	< _ u	ser Groups- ther	Group ID:	1	->
	Login shell:	< n	listgrp list1	>	>	·
	Assign password	? n n	list2 list3			
	OK	_ n _ n	list4 list5 list6]	HELP	
				1		
, <u> </u>						

Move to the login group you want and press **ENTER** to select it.

Group ID

This information field contains the group identification number assigned by the system. You cannot alter this field.

Login shell

This field contains the user's default login shell. To select a different shell, pop up the list of available shells. Your screen will look similar to this:

Disk	File Mac	hine	Software	e User	Help	Quit	
1			—Add a New	User-			
		Cur	rent User I	Parameters			
	Full name:	rob	in hood				, —
	Login ID:	rob	in	User ID:	668		
	Home directory:	/usi	r/robin				
	Login group:	<ni:< th=""><th>stgrp ></th><th>Group ID:</th><th>100</th><th></th><th></th></ni:<>	stgrp >	Group ID:	100		
	Login shell:	<	User	Shells-			->
	Assign password	? 	/bin/sh /bin/csh /bin/ksh	Bourne shel C shell Korn shell		· -	
	OK		other	Restricted :	EELP		

Move to the shell you want and press **ENTER** to select it.

Assign password?

This field allows you to assign a password for the new user. If you do not want to assign a password, type no. To assign a password, type yes. If you type yes, the following prompts will appear on your screen:

New password: Type new password again:

Type in a password that is a unique word between 6 and 12 characters long. It may include upperand lowercase characters, numbers, and symbols. It is a good idea to include at least two alphabetic characters and one number or symbol. Type the password again at the second prompt. (Note that if you do not assign passwords, users will have to set one the first time they log in.)

4. Now that you have provided the system with the information necessary to add the user, the system creates the new account.

If you do not understand a form or a particular field in a form, press F1 or select the HELP button at the bottom of the form. The system will provide an explanation.

6.4.2 Adding a New Group

 From the User menu select Group Management, then select Add a New Group. Your screen will look similar to this:

Disk File	Machine	Software	User	Help	Quit
		TEM ADMINIS	List A Group	ctive Users Management	->
	Cur: Group Name:	rent Group 1	Parameten Group	:8) ID: 116	Nape ->
	OK	CANCE	-	HELF	
1					_1

The Add a New Group form displayed above contains these fields:

Group Name:

Type the name of the group in this field. It should be a word, number, or abbreviation that is between three and eight characters. A group name may only consist of lowercase letters and/or numbers. Uppercase letters and special symbols are not permitted.

Group ID:

The system supplies a default group identification number (GID) in this field. Press **ENTER** to accept the default GID. If you wish to assign a different GID number, you may override the default by typing a new number over it. Note that since the numbers from 0 to 100 are reserved, sysadm will not accept a number below 100.

2. Now that you have provided the system with the information necessary to add the group, you can either install or cancel the entry. Select the OK button at the bottom of the form to install the entry. Select the CANCEL button to cancel the entry. You will be returned to the Group Management menu.

6.5 Managing Passwords

To log in to the system, both the login name and password must be used. Since the login names are known to other users on the system, the password is very important to system security. Observe the following guidelines when you use or assign passwords:

- A password should be hard to guess. Do not use names, birthdays, telephone numbers, or words that are of personal significance. For example, if you are known to be an enthusiastic sports fan, it is not a good idea to use the name of your favorite team.
- Passwords should be at least six characters long with at least two alphabetic characters and one non-alphabetic character. Note that if you are not the superuser, you *must* follow these guide-lines in choosing a password.
- Never record your password or someone else's on paper.
- Make sure all system users understand the importance of keeping passwords secret.
- Encourage your users to change their passwords occasionally.

6.5.1 Aging User Passwords

Password aging allows the system administrator to set time requirements on passwords to make it harder for others to break into your system. After a specified period of time, passwords expire, and users are forced to enter new ones. Users are also prevented from changing a new password for a specified time. When a login is first assigned, there is no aging. Password aging must be assigned by the system administrator (as the superuser) using the passwd command.

Password aging information consists of the following variables:

• MINWEEKS = number

where *number* defines how soon a user can change a password after it was last changed. MINWEEKS is defined for all users on the system in /etc/default/passwd. The system administrator can also change this variable for each individual user account using the passwd command. The default is 0.

• MAXWEEKS = number number defines the maximum amount of time a user can retain a password for a user account. MAXWEEKS is defined in /etc/default/passwd. The system administrator can also change this variable for each user account using the passwd command. The default is 1000.

• IDLEWEEKS = number number defines the length of time a user's password account is allowed to remain idle without being changed. IDLEWEEKS may be defined in /etc/default/login; by default, it is not defined.

The general form of the passwd command used to set password aging is:

passwd -1 -xmax -nmin login_name

The -x option specifies the maximum number of days (max) that a password is valid for the user named login_name. If max is 0, password aging is turned off for that login.

The -n option specifies the minimum number of days (*min*) that a password is valid for the *name* login. This means that *login_name* is forced to use the same password for at least *min* days.

For example, to force user robin to change his password every 30 days and to keep any assigned password for at least a week, type:

passwd -1 -x30 -n7 robin

See passwd(1) for a complete description of the passwd command.

6.5.2 Changing Other Users' Passwords

Ordinary users can use the passwd command to change their passwords any time (depending on how password aging is set). As superuser, you can change another user's password without knowing his or her password. This is useful when someone forgets a password for some reason.

To change a password, type:

passwd login_name

7. SETTING UP YOUR PRINTER

A printer is added to the system with the sysadm Printer Management option of the Machine menu. Printers can be either serial or parallel. A serial printer must be plugged into a serial port, such as COM1 or COM2; a parallel printer must be plugged into a parallel port, such as LPT1 or LPT2.

The system supports a set of default printer types. However, the printers shown in this section are only examples. Your system may be configured to support additional or different printers. Before you attempt to install a new printer, refer to the documentation provided by your vendor or to your hardware manufacturer's instructions.

You can also refer to section 8.5, "The Line Printer Driver," in the "INTERACTIVE UNIX Operating System Maintenance Procedures" for more information about the line printer driver. Refer to section 9 of that same document for a detailed description of the LP Print Services software, which allows you to tailor your printing environment, for example, to print out specific forms or to support specific features of a nonstandard printer.

7.1 Starting and Stopping the Print Spooler

The print *spooler* is the daemon that provides system-wide control of all jobs queued to all printers on your system. The print spooler should only be turned off when the entire printer system is to be shut down. In this case, you should turn off the spooler and flush the printer queues before shutting your system down. Initially, the print spooler is off; it should be turned on before adding a printer to your system. To stop or start the print spooler, follow this procedure:

1. Select the Spooler Management option of the Printer Management menu. Your screen will look similar to this:

2. The Print Spooler Status form contains these fields:

Spooler status:

This field displays the current status of the print spooler. The two options available are running and not running. If the spooler is running, jobs will be queued to the various printers on your system. If it is not running, the system will not accept or queue jobs to any printer on the system.

To start the print spooler, select the START button at the bottom of the form. To stop the print spooler, select the STOP button. Your screen will be updated to reflect the current state of the spooler.

Default printer:

Access the options in this field to change the default printer for your system. The default printer is the one used by the print spooler when no printer is specified in a command. For example, the command lp filename would cause the print spooler to send the job to the default printer, in this case laser2, since no printer is specified in the command.

3. Select the EXIT button to return to the Printer Management menu.

7.2 Adding a New Printer

To add a new printer to your system, follow this procedure:

- 1. Plug the printer into the appropriate serial or parallel port on your system. It may be located on your main board or on an adapter board. Refer to the instructions provided by your hardware manufacturer to determine the correct connection.
- From the Machine menu select Printer Management, then select Add a Printer. Your screen will look similar to this:

Disk	File Printer to your	Machine	Software	User	Help	Quit	
		сог	nfigure a New	ø Printer			-ı ı
		LP Print S	Service - Pr	inter Parame	ters		
	Printer name:		Cla	ss name:	<none< td=""><td>></td><td></td></none<>	>	
	Alert type: Model type:	<mail< td=""><td>> Fau</td><td>lt handling:</td><td><wait< td=""><td>></td><td></td></wait<></td></mail<>	> Fau	lt handling:	<wait< td=""><td>></td><td></td></wait<>	>	
	<pre>standard (sta</pre>	andard prin	nter interfa	ce program)		>	
	Type of hardwa	are interfa	ace: <;	parallel>			
	Device name:	<td>ll > Fore</td> <td>ce Banner?</td> <td><yes></yes></td> <td></td> <td></td>	ll > Fore	ce Banner?	<yes></yes>		
	DESCRIPTION:						
			CANCE	.]	HELD		
		`	CANCE				

3. The Configure a New Printer form contains these fields:

Printer name:

Type the name of the printer. For example, type laser1. You may not skip this field.

Class name:

A class name can be used to group printers in any way you prefer. You may use a class name instead of a printer name when you send a job to a printer. For example, you might specify lasers as the class name for all laser printers on your system. You may then specify the class name instead of a specific printer name when you send your job. The print spooler will attempt to print the job on the first printer in the lasers class. If this printer is busy, the job will be sent to each printer in the class, in turn, until one is found that is available to print the job.

Alert type:

This field allows you to specify how the system should notify you when a problem is detected with the printer. The system default is mail. This means that a mail message will be sent when a problem is detected. If you want to specify a different method of notification, pop up the list of which alternative options. are write. no alert, and custom. The write option will send a message directly to your screen when a printer problem is detected. The no alert option will prevent the sending of any alert messages. The custom option is provided so that you can specify to whom alert messages should be sent. By default, messages are sent to root. If you want to specify other users instead of or in addition to this user, use the custom option.

Fault handling:

This field allows you to specify what the printer should do once a problem has been taken care of. The default is wait, which means that the printer will wait for further instructions once a problem has been cleared. To specify a different type of fault handling, access the options continue and restart. The continue option directs the printer to continue printing the current job from the point where it was stopped. This option is only useful if your interface can detect the current position of the job. The restart option directs the printer to start printing the job from the beginning once the problem is cleared.

Model type:

In this field, provide the name of the interface program. The default standard program should work with most printers. However, if you want to specify another interface program, pop up the list in this field and select the appropriate interface for your system. The last option on the list is other, which allows you to specify an interface program that is not already listed.

Type of hardware interface:

In this field, specify the type of hardware interface. The default is parallel, but you can toggle the spacebar in this field if you want to specify serial. Depending on which option you select, you will need to indicate some specifics such as the baud rate for your type of hardware interface.

Device name:

In this field, specify the appropriate device name for your interface. The system default is /dev/null. To specify a different device name, access the list in this field and select an appropriate name. If the device name you want is not listed, select the other option and type the name in the box provided. The list of device names that appears when you access the menu in this field is constructed according to whether you select serial or parallel in the Type of hardware interface: field. If you select serial, the list will look similar to this:

```
/dev/tty00
/dev/tty01
other
```

/dev/tty0 corresponds to the first serial port, and /dev/tty01 corresponds to the second serial port. If you select parallel, the list will look similar to this:

/dev/null /dev/lp other

/dev/null is the system default, and /dev/lp is the first parallel port on the system.

Note that in order to make the entries on these lists available for use, the appropriate hardware must be present.

Force Banner?

This field allows you to specify on a system-wide basis that a banner page should be printed with each job. The default setting in this field is yes. A yes in this field, overrides an individual user's command and prints a banner page for every job. If you select no, an individual user can specify on the command line that a banner page should be printed for a particular job.

DESCRIPTION:

You may use this field to add a line of text describing the printer, since printer names are sometimes cryptic.

- 4. Now that you have provided the system with the information necessary to add the printer, you may install the entry by selecting the OK button at the bottom of the form. If you wish to delete the entry, select CANCEL. You will be returned to the Printer Management menu.
- 5. Test your new printer by sending a file to it using the lp command.

7.3 Instructing a Printer to Accept or Reject Print Jobs

At times you will want to instruct a printer to stop accepting jobs, for example, while you perform routine maintenance. At other times, you may want a printer that you have stopped to begin accepting jobs again. The Change Printer Status option of the Printer Management menu provides a way to implement either of these changes. This option also allows you to take a printer off-line temporarily while continuing to queue jobs for it.

1. From the Printer Management menu, select the Change Printer Status option. Your screen will look similar to this:

Disk Display	File Machine Software User Help Quit or change the status of printers on your system	
	Display/Change System Printer Status-	
	LP Print Service - Current Printer Status	
	Printer name: < > Class:	
	if not, reason:	
	Accepting jobs: < >	
	if not, reason:	
	Print enabled: < >	
	OK CANCEL HELP	
	·	

The Display/Change System Printer Status form contains these fields:

Printer name:

Press the spacebar to pop up the list of available printers, then select the appropriate printer.

Class:

The system automatically supplies the name of the class the printer belongs to. If the printer is not part of a class, the word none will appear in this box.

Accepting jobs:

This field allows you to make a printer (or a class of printers) temporarily unavailable by turning off the queue to the printer(s). Access the list of choices in this field and select no or yes. If you select no, jobs will no longer be queued to the printer. In this case, your screen will display a form in which you can provide an explanation of why the printer is not accepting jobs. This explanation will be displayed on the screen when a user tries to send a job to this printer. The form displayed when you select no will look similar to this:

Type your explanation, for example, Routine Maintenance, then select the OK button at the bottom of the form. If you select yes, jobs will once again be queued to the printer.

Print enabled:

This field allows you to take a printer (or a class of printers) off-line temporarily while leaving the queue on. Select no or yes from the list in this field. If you select no, the printer will be disabled but jobs will continue to be queued to it. In this case, your screen will display a form in which you can provide an explanation of why the printer has been disabled. The explanation will be displayed on the screen when a user tries to send a job to this printer. If you select yes, the printer will be put back on-line and will begin to print all jobs waiting in its queue.

7.4 Removing a Printer From the System

If you want to remove a printer from your system, follow this procedure:

1. Select the Delete a Printer option of the Printer Management menu. Your screen will look similar to this:

Disk Remove a	File Machine Software User Help Quit a printer from your system	
ļ	Remove a Printer	
	Printer Name < > Class	
	Alert type Fault	
	handling	
	Model type Hardware	
	interface	
	Force Banner? Device	
	DESCRIPTION:	1
		1
1		
	OK CANCEL HELP	

2. Access the list in the Printer Name field and select the printer you want to remove from the system, for example, laser1. The system displays the printer's configuration, which was set with the Add a Printer option. Your screen will look similar to this:

isk Remove a	File printer from y	Machine Sof our system	tware User	Help	Quit
	T.P	Remov	e a Printer	meters	·
	21		riinter rara		<u> </u>
	Printer Name	<laser1< td=""><td>> Class</td><td>lasers</td><td>i</td></laser1<>	> Class	lasers	i
	Alert type	mail	Fault	wait	ן ר
			handling		J
	Model type	standard	Hardware	parallel]
			interface	, L	-
	Force Banner? DESCRIPTION:	yes	Device	/dev/lp]
				· -	
	Sales departm	ent laser prin	cer]
			1		
	OR		CANCEL	HELP	

3. To remove the printer, select the OK button at the bottom of the form.

8. TAILORING THE ENVIRONMENT

When you first installed your system, you tailored several system parameters, such as the time zone and date. As you become more familiar with the INTERACTIVE UNIX Operating System, you may wish to customize your system to better suit your specific working environment.

An INTERACTIVE UNIX System is usually customized by modifying one or more *configuration files*. These are files that store information that affects the environment of an individual user or affects the system on a global basis. There are several configuration files on the system that may be modified to tailor the environment to meet system-wide or individual requirements.

Every INTERACTIVE UNIX System user operates in a unique environment that is controlled by the shell, the INTERACTIVE UNIX System command interpreter. A number of shell variables are defined at the time the user logs in to control many of the default actions of the user's login session. A variable is a word that is assigned a value and has a special meaning to the INTERACTIVE UNIX Operating System. For example, the default terminal type is a shell variable that is usually set for each user. Additional shell variables determine how commands issued by a user are run.

Many INTERACTIVE UNIX System configuration files are shell command scripts or contain shell variable assignments. To fully understand these concepts, refer to the *User's Guide* for more detailed information about the definition and use of shell command scripts.

Each file has a default configuration that can often be tailored through the use of comments. A comment is a part of a file that is not processed by the program that reads the file. In a shell script, a comment is preceded by a #. In a C program (C is the name of the programming language used to write UNIX System programs), a comment is bracketed by /* and */. In an INTERACTIVE UNIX System text processing file, a comment is preceded by \" or '\", if it occurs at the beginning of a line. Comments are ignored by the system. Thus, you may activate or inactivate commands in system configuration files by adding or removing the comment character(s). Many configuration files on the INTERACTIVE UNIX System use comment lines to explain the function of a command sequence.

8.1 Environment Variables

A number of shell or *environment variables* are set automatically by the system for all users. An environment variable is assigned the value of a *string* (a word, file name, command, or other sequence of characters or letters). A system administrator may want to change some of these variables in the system's default profile (/etc/profile), or an individual user may want to change them in his or her own .profile.

The syntax for assigning a value to a variable is:

variablename=value

(Note that there are no spaces.) For example, the HOME variable is set equal to the path name of the user's home directory:

HOME=/usr/deb

The environment variables that are usually defined by default are listed alphabetically below.

CDPATH

Defines the paths to be searched for an argument to the cd command. By default, the current directory is searched.

HOME

Defines the path name of your login directory. The value of HOME is set when you log in and should not be changed. HOME is specified in /etc/passwd.

ΗZ

Defines the number of ticks per second for the system clock.

IFS

Defines the internal field separator characters. The shell initially sets these characters to include the space (blank), tab, and newline characters.

LOGNAME

Defines your login name and is set when you log in to the system. This variable is often referred to by shell programs. LOGNAME is specified in /etc/passwd.

MAIL

Defines the full path name of the directory where you will receive mail from other users. MAIL is usually kept in /usr/mail(i.e., /usr/mail/LOGNAME).

MAILCHECK

Defines the interval at which the system checks for new mail (in seconds).

PATH

Defines the directory search path for commands. By default, this variable includes the current directory, the /bin directory, and the /usr/bin directory.

PS1

Defines the primary shell prompt. By default, the shell prompt is set to \$ for regular INTERACTIVE UNIX System users and # for users who log in as root.

PS2

Defines the secondary shell prompt. By default, the secondary shell prompt is set to >. When this prompt appears, it means that additional information (input) is needed for the command to run.

TERM

Defines your terminal type for certain programs (such as screen editors). By default, TERM is set to AT386.

ΤZ

Defines the time zone in which the computer is located.

8.2 The System Default Profile

When you first log in to the INTERACTIVE UNIX System, your working environment is defined by the default system profile located in /etc/profile. This file is a shell script that is executed each time the Bourne shell is started. It contains the commands needed to initialize your environment and the commands common to all users.

/etc/profile executes a sequence of commands and sets a number of shell (environment) variables. /etc/profile also runs a number of commands. It displays the message of the day and runs umask, the command that determines the default protections for new files and directories created by users. (Refer to section 14.4 for more information about the umask command.) In addition, /etc/profile may be tailored to run other programs that should be run when a user first logs in, for example, the news program. Here is a sample /etc/profile file:

```

You must be logged in as root to modify the default system profile. Use an editor supplied with your system to modify this file.

8.3 The Individual's .profile

Individual users can further customize their environment by creating a personal version of /etc/profile, named .profile, that is stored in the user's login directory. .profile may be used to reset any of the environment variables listed above to suit the individual's requirements better than the system defaults. The system reads .profile *after* it reads /etc/profile, so the variables set in .profile "override" the system defaults. Here is an example of a typical .profile:

```
PATH=:/bin:/usr/bin:$HOME/bin
SHELL=/bin/sh
MAIL=/usr/mail/deb
TERM=wyse60
export.PATH SHELL MAIL TERM
```

The export statement is used to make the variables apply to every environment the user enters.

After creating or making changes to the .profile, you can initiate the changes by logging off and logging back in again or you can type:

. .profile

and press **ENTER**. The shell will reinitialize your environment. The dot (.) is a special shell command used to execute commands in command scripts such as .profile.

To look at the variables set in your environment, you can use the set or env commands. Type:

env

```
or
```

set

and press **ENTER**.

You can set an environment variable temporarily, so that it applies only to the current login session, by typing it at the system prompt. For example, if your TERM variable is set to AT386 because you usually use the system console, but you want to temporarily log in on a DEC* VT100* terminal, type:

\$ TERM=vt100 export TERM

and press **ENTER**. For that login session, your terminal type is vt100. The next time you log in, your **TERM** variable will be AT386, as usual.

8.4 Setting System Date and Time

System time under the INTERACTIVE UNIX Operating System is controlled and affected by several different factors. Each of the following items plays a role in the date and time that users and programs observe:

- System clock
- CMOS RAM
- User environment
- Daylight Saving Time
- setlocale program

Your computer has an electronic quartz clock powered by a small battery. This clock runs all the time, even when the computer is off. The computer operator can set the date and time that the clock maintains in one of four ways:

- The hardware manufacturer's setup program
- The ROM BIOS setup program, accessed by a "hot-key" before booting the system
- The date command
- The sysadm setconf command

The actual time displayed by the clock depends on the settings stored in CMOS RAM (CoMplementary Oxide Silicon). This type of memory requires very little energy to maintain. The CMOS RAM memory is powered by the clock battery, even when the system is off. In addition to the date and time, system configuration information is also stored here. Usually, the manufacturer's *setup* utility or *setup* program is used to change the system date and time.

If you use the sysadm setconf command or the date command to change the date or time, the change will be made permanently, updating both the time stored in the CMOS RAM and the UNIX System time.

When the UNIX System kernel is booted, it reads the system date and time from the CMOS RAM. The UNIX System determines which time zone it is running in from the TZ environment variable (set by /bin/sh as part of the system startup process). The TZ environment variable contains the main local time zone, the difference between the main local time zone and Greenwich Mean Time (GMT), and a possible alternate time zone, e.g., for areas that use Daylight Saving Time. The information in TZ is used in the calculation to convert the local time from the CMOS RAM to GMT, which is the time used internally by the UNIX System kernel. When the system displays dates and times, it converts GMT to the local time, again using the TZ environment variable to adjust for the local time zone. The default time zone used initially by the system is Eastern Standard Time.

The user's environment affects programs that use or display the date and time, for example the date program. When the user logs in. the login program sets the TZ environment variable from the TIMEZONE value in the file /etc/default/login. For Bourne shell users (this is the default user environment), the TZ environment variable will be overridden by the value in /etc/TIMEZONE, which is executed via /etc/profile when invoked by login. For C /bin/sh is shell users /etc/TIMEZONE will not be executed, so it is important that both /etc/default/login and /etc/TIMEZONE are changed from the default Eastern Standard Time to contain the correct time zone for the system.

In areas that use Daylight Saving Time, local time is moved forward or backward at different times of the year. If the system is running during a change to or from Daylight Saving Time, the programs that use or display dates or times will correctly reflect the new date and time as long as the TZ environment variable appropriately specified the alternate time zone. However, the CMOS RAM time does not automatically change, so the next time the system is booted, the kernel will reinitialize the date and time based on the CMOS RAM, and it will thus revert to the old time. The date and time in the CMOS RAM must be updated manually using one of the methods specified above.

8.4.1 Resetting the System Date and Time

Use the sysadm setconf command to access the form that will allow you to reset the system date and time. Your screen will look similar to this:

```
Disk
           File
                     <u>Machine</u> Software
                                            User
                                                       Help
                                                                  Quit
Display or change CMOS system parameters, such as time, date, and time zone
                     Display/Change System Configuration-
                      Current 'sales' System Configuration
                                Date: Aug 02 1991
                                                     Time: 03:37:08 PM
      Machine name: sales
      Number of diskette drives: <1>
                                           Reset time?
                                                             < no >
      Drive 0 type: <3.5-inch HD/DD
                                       >
                                           Reset date?
                                                             <no >
      Drive 1 type: <not installed
                                       >
                                           Time zone: <PST8PDT
                                                                    >
      Math coprocessor present? <no >
                                         Daylight saving: <yes>
                                    CANCEL
                                                          HELP
                 OK
```

This form displays a number of fields that you can explore on your own. Only the fields needed to set the date and time are discussed here.

- 1. **TAB** to the Resettime? field and select yes. The system displays another form in which you can use the space bar to set the current hour, minute, second, and to select a.m. or p.m.
- 2. When you have completed the form, select the OK button at the bottom of the form. The system returns to the Display/Change System Configuration form.
- 3. **TAB** to the Reset date? field and select yes. The system displays another form. Use the spacebar to set the current month, day, and year, then select the OK button to return to the Configuration form.
- 4. If you want to change the time zone, **TAB** to the **Time zone:** field and use the spacebar to pop up a list of time zones. Select the time zone you want to use; you will be returned to the Configuration form.
- 5. **TAB** to the Daylight saving: field and use the spacebar to select yes or no.

6. Select the OK button at the bottom of the form. The system date and time are set.

8.5 Setting Up a Message of the Day

Your system may be set up so that a message-of-the-day is displayed whenever a user logs in to the system. The text of the message is stored in the file /etc/motd. You can modify this file, using an editor delivered with your system, to add important messages that should be seen by all system users. It is a good place to put messages regarding scheduled system downtime or other daily reminders. Here is a sample /etc/motd file:

```
***** The system will be down tonight *****

***** from 5:00 p.m. to 7:00 p.m. for *****

***** scheduled system maintenance. *****

***** The new Networking Package is *****

***** installed. Problems to operations. *****
```

The message-of-the-day is displayed each time a user logs in to the system and whenever you use the sysadm command or login.

8.6 Changing the News

The message of the day should be used for important, but short announcements. If you have longer messages you want to put in a location accessible to all users, use the /usr/news files. Use one news file per news item. To add or change news, create a file in the news directory and type in the news you want system users to read. To read the news after logging in, each user types news and presses **ENTER**. See *news*(1) for more information about news.

8.7 Automatic Program Execution

8.7.1 The cron Program

The cron program runs other programs automatically at specified times. This program and, more specifically, the crontab command, allow you to run programs during off hours such as:

- File system administration
- Long running, user-written shell procedures
- Cleanup procedures

Any task that needs to be done repeatedly at a specific time can be put into the cron file, which is located in the /usr/spool/cron/crontabs directory. If authorized by the system administrator, users can use the crontab command to establish their entries.

The crontab command has several options, shown in the following table:

Command	Result
crontab	Copies the standard input from the screen into a directory that holds all users' crontabs.
crontab file name	Copies the named file into a directory that holds all users' crontabs.
crontab -r	Removes a user's crontab from the crontab directory.
crontab -1	Lists the crontab file for the invoking user.

See crontab(1) for additional information.

Each line in the crontab file defines one procedure. For example:

minute hour day month day-of-week command

Each field is defined as follows:

Field	Definition
minute	0-59
hour	0-23
day	1-31
month	1-12
day-of-week	0-6 (0=Sunday)
command	the command to be executed
	at the time specified

The following rules apply to the first five fields:

• Two numbers separated by a hyphen indicate a range of numbers between the two specified numbers.

- A list of numbers separated by commas indicates that only the numbers listed will be used.
- An asterisk specifies all legal values.

For example, 0 0 1, 14 * 2 indicates a command will be run on the first and fourteenth of each month, as well as on every Tuesday. If a percent sign (%) is placed in the command field (sixth field), the INTERACTIVE UNIX System translates it as a new-line character. Only the first line of a command field (character string up to the percent sign) is executed by the shell. Any other lines are made available to the command as standard input.

For example, suppose a file called anyfile contains the following cron entry:

0 0 1 * * mailx \$LOGNAME % Subject: Call Mom! % now

When the command line crontab anyfile is executed, the user whose login is **\$LOGNAME** will get a reminder mail message with Call Mom! as the subject the first of every month.

8.7.2 Automatic System Cleanup

The INTERACTIVE UNIX System should be cleaned up occasionally. Fortunately, the crontab command and crontab file make this task easier. You can specify cleanup jobs (e.g., remove aged files) and the time you want them to execute in the crontab file.

Your system comes with some default cleanup procedures already defined. These cleanup procedures are done by the root login under the control of crontab each Sunday morning at 5:17 A.M. The file /etc/cleanup defines what cleanup procedures are done.

Some of the files cleaned up automatically each Sunday morning are:

/etc/wtmp

This file contains a history of system logins. Every time a user logs in, a record is made in this file. If not cleaned, the size of this file will grow forever. Instead of deleting the contents of this file yourself, cron can do it for you. • /usr/adm/sulog

This file contains a history of users that use the su command to switch logins. As a security measure, this file should not be readable by other users. See su(1) for additional information.

Log in as root and execute crontab -1 to see the crontab entry that executes /etc/cleanup as well as other cleanup routines for UUCP (Basic Networking). Examine /etc/cleanup to see the default routines run each Sunday morning. To change how cleanup jobs are performed, edit /etc/cleanup and modify the root crontab in /usr/spool/cron/crontabs.

9. UNDERSTANDING INTERACTIVE UNIX SYSTEM FILE SYSTEMS

Many of the system administrator's responsibilities involve maintaining and monitoring file systems. This section explains how a file system is structured and the naming conventions that are used to access file systems and peripheral devices (usually hardware). You will use the sysadm File menu to perform most file system maintenance. However, before you can begin using the *utilities* available with the sysadm command, you must understand the definition and the structure of an INTERACTIVE UNIX Operating System file system.

9.1 What Is an INTERACTIVE UNIX System File System?

An INTERACTIVE UNIX System *file system* is a complete directory structure that is contained on a diskette or a fixed disk. It contains a collection of files arranged in a hierarchical order. On a diskette, a file system usually takes up the entire volume. On a fixed disk, a file system is associated with a single subpartition of the INTERACTIVE UNIX System partition on the fixed disk.

There is at least one permanent file system established on the first subpartition of the INTERACTIVE UNIX System partition on the first fixed disk. This permanent file system is known as the *root file system*. The main (top level) directory in the root file system is called the *root directory*. It contains all of the important files and subdirectories that are required to run the INTERACTIVE UNIX Operating System. The root directory is automatically created and given the unique name of / (slash) when your system is installed and initialized. A typical root file system looks like this:

In this example, the file unix in the root directory contains the kernel. The remaining entries are files and subdirectories that

contain text files, command files, shell scripts, and other directories that are used by the operating system.

In addition to the permanent root file system, you may establish additional file systems on fixed disks or diskettes. Additional file systems can be *mounted* on the original root file system. Mounting a file system attaches it to the root directory and makes it accessible to users. If the file system is located on a portion of the fixed disk, it can be automatically mounted when the system is brought up. It is often useful to establish multiple file systems on the fixed disk to improve system performance or to prevent unauthorized access to sensitive data. Fixed disk file systems are created when you install your INTERACTIVE UNIX System and when you install additional fixed disks on your computer. If the file system is established on a diskette, it must be mounted before it can be accessed.

The figure below illustrates a typical INTERACTIVE UNIX System file system structure. The root file system contains one additional mounted file system, usr2. In addition, a user owns a diskette that contains a file system labeled doc. It has not been mounted. To be made accessible to users, the diskette must be physically present in the diskette drive and the file system on it must be mounted.

All files and directories in a file system are accessed using a path name. Path names have the following form:

/name1/name2/name3

where *name1* and *name2* are directory names and *name3* (the last name in the path name) is either a directory name or a file name.

The first slash (/) in the path name is the name of the root directory. The subsequent slashes in the path name are used to separate the directory names and file names. Once you have mounted a file system, it appears to be an ordinary directory that is part of the root file system and is accessible by standard INTERACTIVE UNIX System naming conventions. For example, when the doc file system described above is mounted under the /mnt directory, the file system will look like this:

To access the file called report, use the path name:

/mnt/report

The file system is still the one labeled doc on the diskette, but the label is not used while the file system is mounted on the root directory.

9.2 File System Naming Conventions

Before you can begin any routine maintenance of the file system, you must understand the basic conventions that are used to name file systems and devices. When you mount a file system, back up a file system, or check a file system for errors, you may need to identify the device on which the file system is located. This section outlines the naming conventions for file systems on the INTERACTIVE UNIX System. The next section outlines the naming conventions for the most common devices found on your system. For more detailed information, refer to section 8 of the "INTERACTIVE UNIX Operating System Maintenance Procedures." A file system name or "label" may be up to six characters in length and may contain upper- or lowercase letters and/or numbers. You should not use any characters in a file system name that have a special meaning to the shell. For example, *, ?, and & are used by the shell and should not be used in file system labels.

It is a good idea to give the file systems meaningful names. For example, if you are creating a new file system that will be used exclusively by the Documentation department, you might label the file system doc. Depending on the size of your fixed disk and the INTERACTIVE UNIX System partition, the INTERACTIVE UNIX System creates one or more file systems when you install it. If only one is created, it is named root; if two are created, they are named root and usr. If created, the third file system is named usr2 and so on, through usr5. If you like, these names can be altered during installation.

9.3 Mount Point Conventions

A file system is attached to the root directory through a process called mounting. Mounting a file system "tells" the system where the file system is located. The file system is mounted onto a directory in the root directory with a system administration procedure called mount (this is discussed in more detail in section 11).

You must create a directory (using mkdir) to be used as the *mount point* for the file system. A mount point is a directory where the file system will be installed. Only one file system at a time can be installed on a mount point directory. The mount point directory may already contain other files and directories, but they will be inaccessible if a new file system is mounted on that directory. These existing files and directories are not deleted, but they remain "hidden" until the newly mounted file system is deactivated or "unmounted." You should warn the users on your system not to put any files into the mount point directory because the files will be unavailable to them while a file system is mounted there.

Both fixed disk and diskette file systems must be mounted to be used. By convention, diskettes are often mounted under a directory named /mnt. This is a convenient way to remember the file system name of all diskettes. It also eliminates the need to create extra directories under the root directory. By convention, directories created under the root directory for mounting fixed disk file systems are usually given the same name as the file system itself. The diagram below illustrates how a directory serves as a place to mount a file system. The root file system is shown below on the left, and the unmounted sales file system on the fixed disk is shown on the right:

After you have created a directory under the root directory called sales and have mounted the sales file system there, it would look like this:

The complete path name to the directory where the sales file system is mounted is /sales.

You may create several file systems on a fixed disk during system installation or when adding a new fixed disk to your system. Refer to section 4 of the "INTERACTIVE UNIX Operating System Installation Instructions" for more information about creating file systems. Create a new directory under the root directory for each new file system. The directory name should be the same as the file system label. This makes it easier to remember the location of each new file system. For example, if you create a new file system labeled doc, create a new directory in the root directory called doc. The complete path name to the directory where the doc file system is mounted is /doc. You can also use this convention for diskette file systems, but it is more common to use only one directory, /mnt, for mounting file systems on diskettes. (The illustrations in section 9.1 show the process of mounting a diskette file system on the root file system.)

9.4 Device Naming Conventions

The hardware devices attached to the INTERACTIVE UNIX System are named and accessed using ordinary path names. Device files are called *special files* because they do not contain data; they are references to the actual programs that run the peripheral devices attached to your computer. These programs are called *device drivers* and are used to control terminals, fixed disks, and diskette drives (among other things).

Note that device names are arbitrary in most cases. The INTERACTIVE UNIX System is supplied with certain preestablished device names. These are adequate for most needs. System administrators may create additional special files or links between existing special files at their discretion. (Refer to ln(1) for more information about linking files.)

By convention, device files reside in a special directory called /dev. There are two basic types of device files: *character files* and *block files*. Character devices, such as terminals, generally process data one character at a time. Block devices, such as fixed disks, access hardware one block (sector or record) at a time. The INTER-ACTIVE UNIX System accesses a file system via a block device.

The device files for both fixed disks and diskettes reside in two parallel subdirectories, rdsk and dsk, under the directory /dev. rdsk stores character device files, and dsk stores block device files. Each device file has a unique name, which may appear in the dsk directory or the rdsk directory, or both. The device file name describes the physical attributes of the device it refers to. The naming conventions for diskettes and fixed disks are different; they are described in the following sections. As a system administrator, you need to know the names of the devices on your system because certain errors are reported in connection with specific devices. Device names for mountable file systems are always found in /dev/dsk, unless they are XENIX* file system names, which are located in /dev. (For a discussion of XENIX diskette device file names, see section 9.4.6.) Note that some special files are also located in /dev/SA and /dev/rSA. These directories are used by the sysadm program to determine some device names.

9.4.1 fdisk Partitions and INTERACTIVE UNIX System File Systems

When the INTERACTIVE UNIX System is installed, its fdisk program is used to divide the fixed disk into *partitions*. You may have only one partition that takes up the entire fixed disk, or you may have several partitions, each containing its own operating system, such as UNIX or DOS. The partitions that divide up the entire fixed disk and are used to hold different operating systems are referred to in this document as fdisk partitions.

Even if you have multiple fdisk partitions, the INTERACTIVE UNIX System is installed on only one. This partition is itself subdivided into a number of sections that are sometimes referred to in technical documents as partitions. To avoid confusion, we refer to these subdivisions of the INTERACTIVE UNIX System partitions as subpartitions, since they are divisions of the fdisk partition on which the INTERACTIVE UNIX Operating System is installed. Both types of partitions are described in the following section.

9.4.2 Device Naming Conventions for Partitions on Fixed Disks

A fixed disk device name associated with an INTERACTIVE UNIX System partition has the following format:

ccontroller_numberddisk_numberspartition_number

A fixed disk device name associated with an fdisk partition has the same format, except that the partition number is preceded by a p rather than an s.

ccontroller_numberttarget_number[1 logical unit number]ppartition_number

The controller, disk, and partition numbers are 0-based (counting begins with 0 instead of 1). The controller_number refers to the single controller that most systems have. The controller is named c0. If you add a second controller, it is named c1.

The target_number refers to your fixed disk. Your first fixed disk is named t0; if you have a second fixed disk, it is named t1. Each additional fixed disk adds one to the previous disk's number.

The *logical unit number*, or the option 1, is used if there are multiple logical unit numbers on a single target. Generally this option is not needed.

The *partition_number* refers to the fdisk partitions on your fixed disk, if preceded by a p, or to the "subpartitions" of your INTERACTIVE UNIX System partition if preceded by an s. You must always specify the partition number when naming a device. A typical disk might be partitioned as in the following illustration:

s0 refers to the entire INTERACTIVE UNIX System partition and is generally used for maintenance purposes (for example, in repairing a damaged disk). The first actual subpartition is called s1. Each subsequent partition number (up to s9) is incremented by one until the last, which is called sa.

Certain INTERACTIVE UNIX System subpartitions are reserved for use by the system and cannot be accessed by user programs. These are: s2 (the *swap area*, which is used to store portions of programs or data that have been temporarily swapped out of main memory), s8 (a small partition that stores the bootstrap program), and s9 (used to store alternate sectors that will be substituted for bad sectors in other partitions).

The remaining subpartitions (s1, s3 through s7, and sa) are used to store program and data files. Of these subpartitions, only the first, s1, is required. This subpartition contains the root file system, where system files and programs are stored. This subpartition must be located on the first (primary) fixed disk.

If present, subpartition s3 contains the usr file system, which is used to store some system files, and possibly users' files. Subpartitions s4 through s7, if present, contain user-specified file systems, typically named usr2 through usr5. These file systems are used to store users' files. Finally, partition sa, if present, contains the tmp file system, which is used to store temporary files and data. (If separate usr and tmp file systems are not created, their function is performed by the usr and tmp directories in the root file system.)

If you have a small fixed disk, it may contain only one partition, with the root file system located on it. If you have a larger disk, or have two fixed disks, then these will contain additional partitions. Subject to size constraints, you may specify during installation how your fixed disk is to be partitioned. Refer to the "INTERACTIVE UNIX Operating System Installation Instructions" for more information about partitioning your fixed disk. For more information on the optimal division of file systems between different fixed disks, refer to section 4.8, "Adding a Second Fixed Disk," in the installation instructions.

The default organization of INTERACTIVE UNIX System subpartitions is described in the following table. The last two columns indicate, for both the first (primary) and additional disks, whether the specified partition is required or optional. Note that file system names must be unique, so that it is not possible, for example, to create a file system named usr on both the primary disk and the second disk.

Partition Name	Contents	Primary Disk	Additional Disks
p0	used for maintenance purposes only (refers to entire disk)	required	required
sO	used for maintenance purposes only (refers to entire INTERACTIVE UNIX System subpartition)	required	required
s1	contains the root file system	required	no
s2	contains the swap area	required	optional
s3	contains the usr file system	optional	optional
s4	contains user-specified file system	optional	optional
s5	contains user-specified file system	optional	optional
s6	contains user-specified file system	optional	optional
s7	contains user-specified file system	optional	optional
s8	contains the bootstrap area	required	required
s9	contains alternate sector space	required	required
sa	contains the tmp file system	optional	optional

These partitions are automatically created by the system when you install your disks.

9.4.3 Examples of Device File Names for Fixed Disks

The complete device file name for the second (first usable) partition of the first fixed disk on a system with one controller is /dev/dsk/c0t0s1. If you have only one controller, the name is abbreviated to /dev/dsk/0s1 by shortening c0t0 to 0. In the INTERACTIVE UNIX Operating System, c0t0 is always shortened to 0 for convenience, although the full names (c0t0 ...) are presented for completeness.

The device file name for the third subpartition of the second fixed disk on a system with one controller is abbreviated to /dev/dsk/1s3.

If you have only one partition on a single fixed disk, the device file name is /dev/dsk/0s1.

The table below shows some common device file names for fixed disks that reside in the directory /dev/dsk. Your system may not require all of these special files.

Common Fixed Disk Device File Names			
Controller Number	Fixed Disk Number	Partition Number	Device Name
1	1	1	0s1
1	1	2	0s2
1	2	1	1s1
1	2	4	1s4
2	1	1	c1t0s1
2	1	2	c1t0s2
2	2	1	c1t1s1

9.4.4 Device Naming Conventions for Diskettes

The naming conventions for diskette devices are as follows:

fdiskette_number[d, q]number_sectors[d, dt]

The term *diskette_number* refers to your diskette drive number. 0 designates the first (or only) drive, sometimes referred to as the A drive. If you have two drives, the second drive is designated 1. Do not type the brackets shown in the statement above. They indicate the options that may be available to you. Use d if you have a

double-sided, double density drive, and q if you have a high density (quad) diskette drive.

The term *number_sectors* refers to the number of sectors per track on your diskette. Use 8 for single density diskettes, 9 for most double density diskettes, 15 for high density 5¼ inch diskettes, and 18 for high density 3½ inch diskettes. Select dt if you plan to use the entire diskette, including the first cylinder (the boot block). Select d if you plan to begin reading and writing on the diskette with the second cylinder.

9.4.5 Examples of Device File Names for Diskettes

If you have a high density $5\frac{1}{4}$ inch diskette in the first drive and you plan to use the entire diskette, you will use the device file name f0q15dt. The complete path name to this device is /dev/dsk/f0q15dt.

If you have a high density $3\frac{1}{2}$ inch diskette in the second drive and you plan to use the entire diskette, use the device file name flq18dt to access the second drive. The complete path name to this device is /dev/dsk/flq18dt. The table below shows some standard diskette device file names. The most common device file name is listed first in each category, followed by other valid names, or aliases.

Common Diskette Device File Names			
File Name	Description		
/dev/dsk/f0d9dt /dev/dsk/f05d9t /dev/SA/disk0_360k	first drive, 5 ¼", double density diskettes, 360K		
/dev/dsk/f0q15dt /dev/dsk/f05ht /dev/SA/disk0_1.2M	first drive, 5 ¼", high density diskettes, 1.2MB		
/dev/dsk/f0q9dt /dev/dsk/f03dt /dev/SA/disk0_720k	first drive, 3 1/2", double density diskettes, 720K		
/dev/dsk/f0q18dt /dev/dsk/f05qt /dev/SA/disk0_1.44M	first drive, 3 ½", high density diskettes, 1.44MB		
/dev/dsk/f1d9dt /dev/dsk/f15d9t /dev/SA/disk1_360k	second drive, 5 ¼", double density diskettes, 360K		
/dev/dsk/f1q15dt /dev/dsk/f15ht /dev/SA/disk1_1.2M	second drive, 5 ¼", high density diskettes, 1.2MB		
/dev/dsk/f1q9dt /dev/dsk/f13dt /dev/SA/disk1_720k	second drive, 3 ½", double density diskettes, 720K		
/dev/dsk/f1q18dt /dev/dsk/f15qt /dev/SA/disk1_1.44M	second drive, 3 ½", high density diskettes, 1.44MB		

There are also four generic diskette device files that automatically determine the density of the diskette. These support 360K and 1.2 MB 5 $\frac{1}{4}$ inch diskettes and 720K and 1.44 MB 3 $\frac{1}{2}$ inch diskettes (the entire diskette). These files are:

/dev/fd0	block device, first drive
/dev/fd1	block device, second drive
/dev/rfd0	character device, first drive
/dev/rfd1	character device, second drive

Note that an unformatted 360K 5 $\frac{1}{4}$ inch diskette cannot be formatted in a 1.2 MB drive and an unformatted a 720K 3 $\frac{1}{2}$ inch diskette cannot be formatted in a 1.44 MB drive using the generic device files.

9.4.6 XENIX Diskette Device Files

The INTERACTIVE UNIX Operating System also supports XENIX diskette device file names. The following table shows INTER-ACTIVE UNIX System device names and their XENIX equivalents.

INTERACTIVE UNIX Operating System and XENIX Diskette Device File Names			
INTERACTIVE UNIX System Names	XENIX Names		
/dev/dsk/f0d8dt	/dev/fd048ds8		
/dev/dsk/f0d9dt	/dev/fd048ds9		
/dev/dsk/f0q15dt	/dev/fd096ds15		
/dev/rdsk/f0d8dt	/dev/rfd048ds8		
/dev/rdsk/f0d9dt	/dev/rfd048ds9		
/dev/rdsk/f0q15dt	/dev/rfd096ds15		

9.4.7 Device Naming Conventions for SCSI Tapes

The naming conventions for tape devices are as follows:

[n]rmtccontroller_numberttarget_number[llogical unit number]

The n option should be used for devices that are "non-rewind."

The controller_number refers to the single controller found on most system. This is the boot controller or 0. If you have a second controller, it is named 1.

The *target_number* refers to your tape device. This is the SCSI identification number set by the manufacturer of the device.

The *logical unit number* is used if there are multiple logical unit numbers on a single target. Generally this option is not needed.

Common SCSI Tape Device File Names			
Controller Number	Tape ID Number	Device Name	
0	0	[n]rmt0t0	
0	1	[n]rmt0t1	
1	0	[n]rmt1t0	
1	1	[n]rmt1t1	
2	0	[n]rmt2t0	
2	1	[n]rmt2t1	

The table below shows some common tape device file names.

Note that the first tape device on your system can be accessed using the name /dev/tape (or /dev/ntape for a non-rewind device). If you have a second SCSI tape device, you may find it convenient to create a link to it with a command like the following:

ln /dev/rmt0t1 tape2

10. USING UTILITIES WITH THE DISKETTE DRIVE

Utilities are provided with the INTERACTIVE UNIX System to read and write data to and from diskettes. These utilities allow you to perform the following basic diskette operations:

- Format diskettes
- Erase diskettes
- Verify diskettes
- Copy files from the fixed disk to diskettes
- Copy files from diskettes to the fixed disk
- Duplicate diskettes

The INTERACTIVE UNIX System provides access to several types of diskettes. A diskette is accessed through either block or character (raw) device names. For information about INTERACTIVE UNIX System device names, refer to section 9.4.

10.1 Formatting Diskettes

Before a diskette can be used in any diskette operation, it must be formatted. You can use the sysadm program to format diskettes, or you can use the format command directly.

10.1.1 Formatting a Diskette Using sysadm

 If you are using a new diskette, access the sysadm Disk menu, select Diskette Management, then select Format a Diskette. Your screen will look similar to this:

- 2. In the first field, select the option that corresponds to the type of diskette in the drive you want to use (remember that disk0 is drive A and disk1, if available, is drive B). Check your manufacturer's documentation to determine this if you are unsure. Note that if you have a high density diskette drive, you can format both low and high density diskettes. The first option selects a high density diskette in the first (5 ¼ inch) diskette drive; the second option selects a low density diskette in the first (5 ¼ inch) diskette drive. (Note that other options may appear on your screen depending on what type and how many diskette drives you have installed on your system.)
- 3. In the next field, select the interleave factor. The default interleave factor is 1, but you can specify a different interleave factor by typing over the default.
- 4. Specify whether you want the system to verify the format. By default the system will verify the format, but you can turn off verification by selecting the no option from the list in this field.
- 5. Select the OK button at the bottom of the form, then insert the diskette in the drive. The system formats your diskette. When formatting is complete, you will be asked whether you want to format another diskette. If you want to format

another diskette, select the YES button at the bottom of the form, otherwise, select NO.

The Diskette Management menu includes a number of other options for working with your diskettes. After going through the Format a Diskette option, it should be easy to use the other options, following the on-line instructions. Remember that help is always available in the sysadm program when you press F1 or select the HELP button at the bottom of a form.

10.1.2 Formatting a Diskette From the Command Line

- 1. Determine the diskette type.
- 2. Insert the diskette into the drive.
- 3. Enter the format command followed by the appropriate character device name for that type of diskette.

The following command will format a 1.2 MB double-sided, high density (DSHD) diskette:

\$ format /dev/rdsk/f0q15dt

10.2 Copying Files to a Diskette

Several methods can be used to copy files to a diskette. One method is to format a diskette, create a file system on the disk, mount the file system, and access the diskette as part of the INTERACTIVE UNIX System directory structure. This might seem a bit complicated, but it is a very convenient way to create a portable file system.

Simpler methods involve using the cpio command with other commands, such as find or ls, or using the tar command.

10.2.1 Copying Files Using cpio

The cpio command copies files to and from diskettes by taking a list of files from standard input and creating a file archive that can be redirected to a diskette. Several commands can be used to supply the file names to be archived by using the INTERACTIVE UNIX System shell pipe facilities. For example, to copy all the files in the current directory to a 1.2 MB diskette:

- 1. Insert a formatted 1.2 MB diskette into the drive.
- 2. Change directory to the directory containing the files to be copied.
- 3. Type:

\$ ls ¦ cpio -oc > /dev/dsk/f0q15dt

In this example, 1s lists the files in the current directory and pipes the list to cpio. Then cpio archives them and redirects the output to the diskette drive.

Similarly, any files copied onto a diskette using the cpio command can be copied back to the fixed disk using different cpio options. The following example copies the files that were copied to a diskette in the previous cpio example back to the fixed disk into the current directory.

- 1. Insert the diskette containing the cpio archive into the drive.
- 2. Type:

```
$ cpio -ic < /dev/dsk/f0q15dt</pre>
```

Refer to cpio(1) for a complete description of the cpio command.

10.2.2 Copying Files Using the tar Command

As an alternative to cpio, you can use the tar command to transfer files to and from diskettes. The following example copies files from the fixed disk onto a 1.2 MB diskette:

- 1. Insert a formatted 1.2 MB diskette into the drive.
- 2. Change directories to the directory containing the files to be copied.
- 3. Type:

tar -cf /dev/dsk/f0q15dt

These files can then be copied back to the fixed disk using the x option to tar, as follows:

- 1. Insert the diskette containing the tar archive into the drive.
- 2. Change directories to the destination directory where you want to copy the files.
- 3. Type:

\$ tar -xf /dev/dsk/f0q15dt

.

Refer to tar(1) for a complete description of the tar command.

11. FILE SYSTEM MAINTENANCE

When the INTERACTIVE UNIX Operating System is first installed and initialized, a root (/) file system is automatically created. Depending on the size of your fixed disk, you may also have chosen to create one or more user file systems, typically named /usr /usr2,/usr3, and so on. Refer to section 4, "CREATING AND USING INTERACTIVE UNIX SYSTEM FILE SYSTEMS," in the "INTERACTIVE UNIX Operating System Maintenance Procedures" for more information on manipulating file systems on fixed disks.

If you plan to store data on diskettes or to add a second fixed disk to your system, you will need to create and initialize additional file systems. You will use the sysadm Disk menu to facilitate file system management on your system. In this section you will learn how to:

- Create a file system
- Mount a file system
- Unmount a file system
- Check the amount of disk space available for a file system
- Check and repair a file system

11.1 Creating a File System on a Diskette

Before you can create a new file system on a diskette, you must format the diskette. To create a file system on a formatted diskette (a removable file system), use the sysadm command to access the Disk menu. Your file system will use the entire diskette.

If you plan to use the diskette solely to store data using the sysadm backup utilities, you do not need to create a file system on it. Any files or file systems found on the diskette are automatically destroyed by the backup procedures.

To create a file system on a formatted diskette, follow these steps:

 From the Disk menu, select Diskette Management. Then from the File System Management menu, select Create a Diskette File System. Your screen will look similar to this:

- 2. In the first field, select the option that corresponds to the type of diskette in the drive you want to use (remember that disk0 is drive A and disk1, if available, is drive B). Check your manufacturer's documentation to determine this if you are unsure. The first option selects a high density diskette in the first (5 ¼ inch) diskette drive; the second option selects a low density diskette in the first (5 ¼ inch) diskette drive. (Note that other options may appear on your screen depending on what type and how many diskette drives you have installed on your system.)
- 3. The next two fields indicate the number of sectors on the entire diskette and the number of inodes available. The system provides reasonable defaults based on the type of diskette you have chosen. Select the default values to accept them.

If you want to change the defaults, you can type new values over them. For more information about changing a default, press F1 in the appropriate field.

- 4. The FS Type: field is an information field only. You cannot modify this field. S51K indicates that this is a System V 1K file system.
- 5. Select the OK button at the bottom of the form when you have finished.

- 6. When the file system has been created, you will be asked whether you want to make another file system. If you do, select the YES button and follow the procedures given above. If you do not want to make another file system, select the NO button.
- To access the files in the file system you have just mounted (/mnt), exit sysadm and then log in to the system with your ordinary user login. Use cd to access the /mnt file system.

11.2 Mounting a File System

There can be many file systems on an INTERACTIVE UNIX System. The file systems may be located on a number of devices, such as diskettes and fixed disk partitions. To use a file system, the INTERACTIVE UNIX System kernel must have information about the device where the file system is located and must know how to access the device. In addition, users must be able to access the file system with an INTERACTIVE UNIX System path name.

A file system cannot be used unless it is mounted on another file system, usually the root file system. File systems are mounted under the root (/) directory with the mount command or through the sysadm Disk menu. To mount a diskette-based file system, access the File System Management menu of the Diskette Management menu under Disk and select Mount a Diskette File System. Fixed disk file systems are mounted automatically each time you boot the system and are unmounted when you run the shutdown command. You may also use the sysadm option, Mount a Fixed Disk File System, located on the Fixed Disk Management menu under Disk, to mount a fixed disk file system.

It is strongly recommended that you use sysadm chkfdfs and sysadm chkhdfs to perform a file system check before attempting to mount file systems.

11.2.1 Mounting a Diskette-Based File System

sysadm automatically mounts a diskette-based file system when it is first created. Any time you use the diskette after that, you will need to explicitly mount the file system that is on it. Follow these steps to mount a diskette-based file system: From the Disk menu select Diskette Management. Then select Mount a Diskette File System from the File System Management menu. Alternatively, you may type sysadm mntfdfs from the command line. Your screen will look similar to this:

Disk Make a file	File Machine system on a diskette	Software User e accessible to users	Help	Quit
Current D Diskette Fi Qu Cop Era For Ver Fil	isk Usage Management -> Diskette Types disk0_1.2M disk0_360k	a Diskette File Syste File System Mount point: /m	em Dunt Options	
Qu	OK	Access allowed: <	HELP	
		·]

- 2. In the first field, select the drive and type of diskette you want to use. The first option selects a high density diskette in the first (5 ¼ inch) diskette drive; the second option selects a double density diskette in the first (5 ¼ inch) diskette drive. The choices displayed on your screen will depend on what is available on your system.
- 3. In the next field, select the directory in which you want to mount the file system. The default directory is /mnt, but you can specify a different directory by typing the name in this field.
- 4. In the third field, specify the type of access you want to allow on the file system by toggling the space bar and selecting read/write or read-only.
- 5. Select the OK button at the bottom of the form. (If you want to cancel the operation, select the CANCEL button.)

6. When the system is mounted, you will be asked whether you want to mount another file system. If you do not want to mount another file system, select the NO button. If you do, select the YES button and another form will appear.

Now that the file system is mounted, you may access it on the diskette using an ordinary INTERACTIVE UNIX System path name.

Remember that you should always unmount the file system before removing the diskette from the drive. Refer to section 11.3.1 for information on how to do this.

11.2.2 Mounting a File System on the Second Fixed Disk

Although fixed disk file systems are automatically mounted when the system is booted, at times you may need to mount one explicitly, for example, if you unmounted a file system to check or repair it. (Refer to sections 11.3.2 and 11.5.4 for information about unmounting and checking file systems on fixed disks.) A file system on a fixed disk can be mounted using the sysadm command. Before you can mount a file system, you must know two things:

- The name of the device that contains the file system
- The directory name of the file system "mount point"

Refer to section 9.4 for device file naming conventions. You will use the same device file name the system used when it created the file system at the time of system installation or when adding a second fixed disk as described in section 4.8 of the "INTERACTIVE UNIX Operating System Installation Instructions."

 To mount a new fixed disk file system, access the Fixed Disk Management menu of the Disk menu and select Mount a Fixed Disk File System. Your screen will look similar to this:

- 2. The first field asks for the name of the device the file system resides on. Type the name of the device that contains the file system, for example, /dev/dsk/0s4.
- 3. The next field asks for the point where you want to mount the file system. Type the name of the mount point in this field.
- 4. The third field allows you to specify read/write or read-only access for the file system. Select the appropriate option, then press **ENTER**.
- 5. Select the OK button when you have completed the form. You will be asked whether you want to mount another file system. If you do not want to mount another system, select the NO button. If you do, select the YES button and another form will appear.

11.3 Unmounting a File System

Before you can remove a diskette from the drive, you must *unmount* or deactivate it. You must also unmount a fixed disk partition that you do not want to be a part of the active file system.

11.3.1 Unmounting a Diskette-Based File System

You can unmount a diskette file system using the sysadm umntfdfs command. If there are system users or programs using any directory under the mount point of this file system, the unmount will fail.

- 1. Change to any directory not on the diskette, for example, the root directory:
 - \$ cd /
- Access the File System Management option of the Diskette Management menu under Disk, then select Unmount a Diskette File System. Your screen will look similar to this:

3. This form shows the diskette file systems that are mounted. Select the file system you want to unmount, then press the OK button. The system will display another form that gives you the option of unmounting another diskette file system, if you wish. Select YES to unmount another diskette file system, and another form will appear. Select NO if you do not want to unmount another file system.

11.3.2 Unmounting a File System on a Fixed Disk

You can unmount a file system on a fixed disk using the sysadm umnthdfs command. If any system users or programs are using any directory under the mount point of this file system, the unmount will fail.

 Access the Fixed Disk Management menu of the Disk menu and select Unmount a Fixed Disk File System. Your screen will look similar to this:

2. This form shows the file systems that are currently mounted. Select the file system you want to unmount, then press the OK button. The system will display another form that gives you the option of unmounting another fixed disk file system, if you wish. If you do not want to unmount another file system, select the NO button at the bottom of the form. If you do, select YES and another form will appear.

11.4 Checking the Space Available on a File System

You can find the disk space available for each file system on your computer with the df command. To use the df command, type the following at the system prompt:
df

The file system mount point, special device, available space, and available inodes (which determine the number of new files that can be created) will be displayed for each mounted file system. You can also use the df command with a file system argument and display the used and available disk space for that file system. Refer to df(1M) for additional information.

11.5 Checking and Repairing a File System

The INTERACTIVE UNIX Operating System has several reliability features built in. Every time a file is modified, the system performs a series of file system updates. These updates, when written to the disk, produce a consistent file system.

Every time the INTERACTIVE UNIX Operating System is booted, your computer checks the status of each file system. If the system was not shut down cleanly, the fsck program is run. The fsck program is a file system check-and-repair program that uses information that is stored in the file system to check for inconsistencies. If the information it checks does not match, it detects the inconsistency and attempts to repair it. Because fsck runs automatically on any file system with inconsistencies when the system is booted, you should typically not have to run fsck manually.

The fsck program can also be run manually to check diskettes that have INTERACTIVE UNIX System file systems on them; or if you suspect something is wrong with your file system, you may want to check it. This should only be attempted by expert users. For more information about fsck, refer to fsck(1M) and to section 5 of the "INTERACTIVE UNIX Operating System Maintenance Procedures."

11.5.1 File System Corruption and Increasing Reliability

A file system can become corrupt in a variety of ways. Three of the most common ways are:

- Improper system shutdown and startup
- Removing media before unmounting its file system
- Hardware failure

- To help keep your file systems reliable:
 - Never remove a diskette while the disk drive is on (the red light on the disk drive is lit).
 - Never remove a mounted diskette; always unmount it *before* you remove the diskette.
 - Always use the shutdown command to bring the system down. This will unmount all file systems and ensure file system consistency.

11.5.2 Checking a File System

Use the File System Management chkfdfs option under Diskette Management under the Disk menu to run fsck on damaged diskettes. Use the chkhdfs option on the Fixed Disk Management menu under Disk to run fsck on a damaged file system on a fixed disk.

If an inconsistency in the file system is found, $f \in ck$ displays a message describing the problem. If the system experiences a power failure, it is usually possible to recover from it without suffering extensive file system damage. However, if the system experiences a hardware failure, the file system may be damaged beyond repair.

If file system damage is relatively minor, fsck will automatically repair many of the problems it encounters without assistance from you. In some cases the system asks you to confirm the action it plans to take. Let fsck repair as much of the file system as possible. Type y when fsck asks if it should proceed with a repair, or press **ENTER** to accept the defaults. If fsck cannot repair the problem, you may have to reinstall a backup version of the file system.

You may find that badly damaged file systems that cannot be repaired can sometimes be mounted read-only, by using the -r flag from the command line or filling in the appropriate sysadm form with the read-only field set.

11.5.3 Checking a Diskette File System

To check the integrity of a diskette file system, use sysadm.

1. Access the Disk menu, then select the Diskette Management option. Access the File

System Management option, then select Checka Diskette File System. The system displays a form similar to this:

- 2. In the first field, select the option that corresponds to the type of diskette in the drive you want to use. The first option selects a high density diskette in the first (5 ¼ inch) diskette drive; the second option selects a low density diskette in the first (5 ¼ inch) diskette drive. (Note that other options may appear on your screen depending on what type and how many diskette drives you have installed on your system.)
- 3. The FS Type: field is an information field only. You cannot modify this field. It is filled in by the system and tells you what kind of file system you have. In the example above, the file system type is System V 1K.
- 4. In the Check mode: field, you can instruct the system to repair any errors that it detects or, alternatively, to simply report any errors.
- 5. Select the OK button when you have completed the form. The system will display another form that gives you the option of checking another diskette file system. If you do not want to

check another file system, select the NO button. If you do, select the YES button and another form will appear.

11.5.4 Checking a Fixed Disk File System

- 1. To check the integrity of a fixed disk file system, use sysadm harddisk to access the Fixed Disk Management menu under the Disk menu.
 - Before checking the integrity of a fixed disk file system, it is important to make sure all other users are off the system. The checking process starts immediately after you select the appropriate option, so you must warn users before you start this sysadm process.
- 2. Select Checka Fixed Disk File System. The system displays a screen similar to this:

Disk File Run the fsck progr Current Disk Usa Diskette Managem Fixed Disk Mana Qu Remap Disk Add a Fixed Check a Fix Display Fix	Machine Software User Help Quit am to check and, optionally, repair the fixed disk ge ent -> Check a Fixed Disk File System Current File System Parameters Device Name:
Display Fix Mount a Fix Unmount a F Quit	FS Type: Check mode: <report errors="" only=""></report>

- 3. In the first field, type the device name of the file system to be checked, for example, /dev/dsk/0s4.
- 4. The next field is an information field filled in by the system. You cannot modify this field.

- 5. In the next field, instruct the system to repair any errors it detects or, alternatively, to simply report any errors.
- 6. Select the OK button. The system will display a form that gives you the option of checking another file system, if you wish. If you do not want to check another file system, select the NO button. If you do, select the YES button and another form will appear.

12. BACKING UP FILES

Once you have started to use your system, you will need to *back up* the files on your fixed disk (or disks) on a regular basis. The copying of files to removable media (such as a diskette or cartridge tape) is called a *backup*. This minimizes the possibility of lost data caused by hardware failures or operator error. It is important to perform backups on a regular basis because these copies are your only protection in the event of a file system crash.

There are two kinds of backups. An *archival* backup is used to back up all the files and directories on a particular file system. An *incremental* backup is used to back up only those files and directories that have changed since the last complete backup.

You should plan a backup strategy for your system that includes a regular complete backup, supplemented by more frequent incremental backups. You may also transfer a file, a set of files, or the contents of a directory onto a diskette, tape, or other medium for storage.

After performing a backup, keep the removable media in a secure place so that there are always up-to-date duplicates of the files on your fixed disk. If the system should become corrupted or a file is mistakenly removed from the fixed disk, the corrupted or missing files can be copied from the removable media to the fixed disk. The procedure of copying the backup files from the removable media to the fixed disk is called a *restore*.

Use the sysadm File menu to transfer data from your fixed disk to another storage medium, usually a diskette. This section explains how to back up file systems, individual files, or directories onto diskettes.

12.1 Before You Begin to Back Up Your System

When you back up a file system, you must have available either a supply of formatted diskettes, or if your system is capable of backing up onto tape, a supply of cartridge tapes. (Note that you do not need to format tapes for backup.) Depending upon the size of your file systems, a single backup can require many diskettes or tapes. Be sure you have enough formatted diskettes or tapes available to complete the backup procedure before you run the backup procedure. To format a diskette, use the Format a Diskette option of the Diskette Management menu under Disk. You will be guided through the procedure step-by-step.

12.2 Backing Up a File System

1. Access the sysadm File menu. Select Back Up or Restore Files, and then select the option Archival/Incremental Backup. Your screen will look similar to this:

Disk Perform	File complete or	Machine incremental	Software backups	User	Help	Quit
		-Archival/Inc	remental F	ile System	Backup	
		File S	ystem Back	up Options		
s	elect file s	ystems for ba	ckup:			
/ /	/usr /sccs	/usr/spool/sn	L			
		Backup mod	le:	<archival< td=""><td>></td><td></td></archival<>	>	
		Verbose mo	ode:	<yes></yes>		
		Output dev	vice:	<tape< td=""><td>></td><td></td></tape<>	>	
		Update tim	e stamp?	< >		
OR CANCEL HELP						
			_			

2. This form contains the following fields:

Select file systems for backup:

The first field in this form shows the file systems available for backup. You can edit this field to show only the file system(s) you want to back up at this time.

Backup mode:

This field allows you to specify whether you want to perform an archival backup or an incremental backup. An archival backup is a complete backup of the file system. An incremental backup is a partial backup of all files that have changed since the date of the last time stamp. You should perform an archival backup the first time you use the backup option. Remember, when you do an archival backup of a file system, all the files on the specified file system are transferred to diskettes or tape. This may take some time to complete.

Verbose mode:

This field allows you to specify whether you want verbose mode enabled or not. If you select yes, the system will list files as they are backed up. If you select no, the system will not list the files.

- Output device:
 - This field asks you to specify the output device to be used. Press the spacebar to pop up the list of output devices available on your system, and select the appropriate one. If the device you want is not listed, select the other option. A new form will appear that prompts you for the name of the output device on which you want to back up your files. Note that if you have a high-density diskette drive, you can back up onto either low- or highdensity diskettes.
- Update time stamp?

This field allows you to specify how far back incremental backups will go. Each time you perform a backup, you can either update the time stamp to reflect the time of the current backup or leave the time stamp unchanged. When an incremental backup is performed, the system compares the current time stamp with each file's date of modification and backs up all files that have been modified since that time.

- 3. When you have selected the backup options, select the OK button at the bottom of the form.
- 4. Next the system asks you to insert your first backup volume (a diskette or tape) in the drive and press **ENTER**. The system copies all of the files on the named file system onto the backup volume. If more than one volume is required, you are prompted to insert additional volumes.

5. When the backup procedure is finished, label the backup volumes with the date of the backup and the name of the file system (and disk, if you are backing up multiple fixed disks).

The first file the system creates is an archive file, which lists all of the files to be backed up. This provides a convenient way to identify the files included in the backup.

12.3 Backing Up Individual Files and Directories

There may be occasions when you do not want to transfer a complete file system to a diskette. The Back Up Selected Files option may be used to transfer a file, a group of files, or the contents of a directory to a diskette.

1. Access the sysadm File menu and select the Back Up or Restore Files option. Select the option Back Up Selected Files. Your screen will look similar to this:

Disk Select o	File Machine Software User Help Quit certain files, directories, and/or subtrees for backup Back Up Selected Files
	Select Files for Backup
	Starting directory: /
	Include Exclude these EDIT LIST files: EDIT LIST
	Additional (Optional) Selection Criteria Select files larger than: bytes
	Older than: days Newer than: days
	Owner: < > Group: < >
	OR CANCEL HELP

The form includes a number of fields that allow you to tailor your backup to include only the files and directories that you specify.

```
Starting directory:
This field allows you to specify a starting directory
```

for the backup procedure. If you specify a starting directory, you can then use relative path names in the EDIT LIST fields described below.

Include these files:

This field allows you to specify the names of files, directories, and subtrees that you want included in your backup. If you have specified a starting directory, you can use either relative or full path names in this field. Access the EDIT LIST in this field by pressing **ENTER**. Your screen will look similar to this:

Disk Select	File Machine Software User Help Quit certain files, directories, and/or subtrees for backup
	Edit List of Files/Directories to be Backed Up
	Files to be Included in Backup
	Enter list of files/directories, one entry per line: <s> /</s>
	<>
	<>
	<>
	<>
	OK CANCEL HELP
l .	

The first part of each line in this display allows you to specify whether the entry is a file, a directory, or a subtree. Use the spacebar to toggle through the choices (F, D, S, -). A *subtree* is a hierarchical arrangement of files and directories. If you select F, it indicates a single file. If you select D, only the files within the named directory will be included. If you select S, both files and directories within the named directory will be included in the backup procedure. The - symbol allows you to delete an entry. To delete an entry, select the – symbol and the field will be cleared.

Make your selection, then type in the name of the file or directory you want to include. Enter as many file or directory names as you want, one per line, then select the OK button at the bottom of the form to return to the previous form (Select Files for Backup).

```
Exclude these files:
```

This field allows you to exclude particular files, directories, or subtrees from the backup procedure. Access the EDIT LIST in this field and follow the same procedure you used to include files. Select the appropriate code (F, D, or S), and enter the file or directory names, one per line. Select the OK button when you have completed the list.

```
Select files larger than: bytes
Older than:
Newer than:
Owner:
Group:
```

These fields in the backup display allow you to specify additional selection criteria for files. You can instruct the system to back up files that are of a certain size or age, or files that belong to a particular owner or group. For example, you might specify a range of files between 30 and 60 days old by specifying 30 in the Older than field and 60 in the Newer than field. When you have entered all pertinent specifications, select the OK button at the bottom of the form. Your screen will look similar to this:

Disk Select cer	File Mac tain files, dire	hine S ctories, Back U	oftware and/or sub p Selected	User i otrees for ba	Help ackup	Quit	
		Select	Backup Opt	ions			
Outp	ut buffer size:	<	>	Verbose mo	de:	<yes></yes>	
Usea	ascii headers:	<yes></yes>		Verify bac	kup:	<no></no>	
	Specify Dest	ination -	Device/F	ile/(Remote)	Command		-
Arch	Archive destination type: <device></device>						
Outp	ut to: <tape< td=""><td></td><td></td><td></td><td></td><td>></td><td></td></tape<>					>	
	OK		CANCEL		HELP]	

- 2. This form provides a number of options for backing up specific files that you select. You can specify the output buffer size, whether you want the backup procedure to report during the process, whether you want ASCII headers on your files, whether you want the system to check that the archive media is readable, what type of backup is to be performed, and what the output device is to be. Toggle the spacebar to pop up the choices in each field and select the appropriate one for your backup. For help with a particular field, press F1 in the field. When you have completed the form, select the OK button.
- 3. The system first creates an archive file, which lists all of the files to be backed up. When the backup process is finished, label the backup medium with the date of the backup and the name of the directories and files.

12.4 Restoring Files

You will need to restore files in the event of hardware or user errors. Your users should be aware that some data may be lost, because any modifications made to the files since the time of the last backup will not be reflected in the restored files.

1. Access the sysadm File menu. Select the Back Up or Restore Files option, then select Restore Files. Your screen will look similar to this:

oisk estore file	File Machine Software User Help es, directories, and subtrees to a fixed disk	Quit
 -	Back Up or Restore Files ->	
	Specify Source - Device/File/(Remote) Command Archive source type: <device></device>	
Input Destin	from: <tape nation directory: /</tape 	>
	OK	

This form includes these fields:

Archive source type:

In this field specify the archive source. Pop up the list of choices in this field and select the appropriate type of archive source. Select device if you are restoring from a tape or a diskette, file if you are restoring from an archive file, and command if, for example, you are restoring across a network.

Input from:

In this field specify the input source you are restoring from. Pop up the list of choices and select the appropriate input source. If you are restoring from diskettes, select the disk drive and type of diskette you are using. If you are restoring from an archive file or using a command, select other and a new form will appear.

Destination directory:

This field allows you to specify where you want your files restored. If you do not specify a path name for the restore procedure, the root directory (/) is used.

2. If you are restoring from a device, make sure the diskette or tape containing the first volume of the backup is in the drive, then select the OK button at the bottom of the form. Your screen will look similar to this:

Disk	File Machine Software User Help Quit					
lestore	files, directories, and subtrees to a fixed disk					
	Restore Files from a Backup	1				
	Solast Pilos for Postora					
	Select Files for Rescore					
	Include Free Exclude					
1	these EDIT LIST these EDIT LIST					
	files: files:					
	Output buffer size: <5120 > Verbose mode: <yes></yes>					
1 1	Use ascii headers: <ves></ves>					
	···· ····· ····· ······ ······· ·······					
1	Create directories if necessary? <yes></yes>					
	keep the original date/time? <yes></yes>					
	Restore only if newer? <ves></ves>					
│						
	OK CANCEL HELP					

3. This form allows you to specify which files you want to have restored. The first five fields are similar to those used in the backup procedure. Enter the names of files you want to include, the names of files you want to exclude, specify an output buffer size, enable or disable verbose mode, and indicate whether you want ASCII headers. (Refer to section 12.3 if you need more information on these fields.)

Create directories if necessary?

In this field, specify whether you want the system to create directories if necessary. Select yes if you want the system to create directories that are not on the fixed disk, if necessary for the restore procedure. Keep the original date/time?

In this field, specify whether you want the files restored with the same date and time stamps they had when they were backed up. If you specify no, the files will have the current date and time stamp.

Restore only if newer?

In this field, select yes to specify that you want to restore only files that have a more recent date and time stamp than the equivalent files on the fixed disk. If you select no, the system will restore all specified files, regardless of the date and time stamp.

- 4. Select the OK button at the bottom of the form. The system will now proceed with the restore operation.
- 5. When the files are copied, the system will display another form that gives you the option restoring more files, if you wish. If you do not want to restore more files, select the NO button. If you do, select the YES button.

12.5 Restoring XENIX Files

The INTERACTIVE UNIX Operating System includes the **xrestore** command, which restores backups that were made under the XENIX Operating System. See *xrestore*(1) for information on restoring XENIX file system backups.

13. MANAGING DEVICES

13.1 What Are Devices and Device Drivers?

In the context of your computer system, a *device* is generally defined as a piece of hardware. For example, a diskette drive, a printer, or an on-board modem are all considered devices. For each device that you use with your computer system, you must have an associated software program called a *device driver*. The device driver is responsible for communicating between the hardware and the application program or operating system. It ensures that the device receives and carries out the instructions given by the user. Drivers for your devices can be supplied with the operating system, with the application program, or by the manufacturer of the device.

The INTERACTIVE UNIX Operating System is delivered with device drivers that support a wide variety of devices, such as commonly used terminals and printers. These drivers support your hardware in its standard configuration and allow you to easily add new devices. Some of these device drivers, such as the line printer driver, are configured into the kernel by default. If you plan to add a device that is already *supported* in this way by the INTERACTIVE UNIX System, it is not necessary to install a new device driver. Section 8 of the "INTERACTIVE UNIX Operating System Maintenance Procedures" details which drivers are already configured into the kernel. To add a printer to your system, refer to section 7 of this document; to add a terminal, refer to section 10 of the **"INTERACTIVE** UNIX Operating System Maintenance Procedures."

Several device drivers that are available with your operating system are not configured into the kernel but are in the *Additional Drivers* optional subset.

13.2 The Kernel

The kernel is the core of the INTERACTIVE UNIX Operating System and all UNIX-based operating systems. It is the program that is responsible for managing the hardware and software resources of the computer. It manages user logins, runs programs, and keeps track of input to and output from devices. The kernel is stored in an ordinary file (/unix) and is tailored to a specific hardware and software configuration. You loaded the standard INTERACTIVE

UNIX System kernel when you installed your INTERACTIVE UNIX Operating System.

If you plan to add new pieces of hardware to your system, in most cases you will have to reconfigure your system to support the new devices. If the type of device you plan to add is not already supported in your standard hardware configuration, then you must also reconfigure the system kernel. This process builds a new kernel that includes the driver for the new device.

INTERACTIVE has attempted to make this process as easy for you as possible by providing two system enhancements. First, a friendly, menu-driven interface called kconfig is provided to help you configure your kernel. kconfig is used to configure, build, and install new kernels. (For additional information about kconfig. refer to section 7 of the "INTERACTIVE UNIX Operating System Maintenance Procedures" and the kconfig(1) manual entry.) Like sysadm, kconfig provides step-by-step procedures that are designed to make it easy to perform a common set of system administration tasks. Second, the High Performance Device Driver is provided to increase the range of supported devices. It is discussed in the following section and in sections 7 and 8 of the **"INTERACTIVE** UNIX Operating System Maintenance Procedures "

13.3 The High Performance Device Driver

The INTERACTIVE UNIX System kernel contains a set of integrated software packages called the High Performance Device Driver (HPDD, for short.) The HPDD allows several controllers to share a single driver, making it easier for you to add and use different types of controllers. It also significantly improves the speed of your system during most operations.

The HPDD supports most AT*-compatible fixed disk controllers, many popular SCSI host adapters (including cartridge tape and CD-ROM support), and a RAM disk. (A RAM disk is created by reserving a portion of the computer's available memory, which is then treated as if it were a disk storage device. Refer to section 8.2 of the "INTERACTIVE UNIX Operating System Maintenance Procedures" for more information about RAM disks. Refer to section 8.2.2 of the "INTERACTIVE UNIX Operating System Maintenance Procedures" for a list of controllers supported by the HPDD.) Each time you add, remove, or change any of *these* devices, you must change your system configuration by:

- configuring the HPDD to support the new configuration,
- rebuilding and installing the kernel, and
- physically installing the hardware (except in the case of the RAM disk).

Note that there are two exceptions to this. If you are replacing a standard AT controller of one type with a different standard AT controller, you do not need to reconfigure the HPDD. (Note that the hardware configuration of the two controllers must be the same.) Also, if you are simply adding a fixed disk drive to a controller that you have already configured, you may not need to reconfigure the HPDD.

You will use the kconfig program to reconfigure the HPDD.

These procedures are discussed in sections 7 and 8 of the "INTERACTIVE UNIX Operating System Maintenance Procedures."

13.4 Tailoring Your System Kernel

Your system kernel is initially configured to support a basic hardware and software configuration. The default kernel includes drivers for the following configuration:

Hardware:

- A keyboard
- A fixed disk and diskette controller
- A monochrome, color, EGA, or VGA display adapter
- Two serial communications ports (COM1, COM2)
- Up to three parallel ports
- A real time clock
- CMOS RAM

UNIX System V Release 3 Software, including:

- MS-DOS* file system service
- UNIX System V file system service
- Common interprocess communication routines, including:
 - -Interprocess communication message facility
 - -Interprocess communication semaphore facility
 - -Shared memory
- Intel* 80387 floating point co-processor (80287 supported on COMPAQ 386*)
- 287 or 387* floating point co-processor emulator

Your vendor may deliver a different default configuration. Check the documentation supplied with your system to determine its default configuration.

You will need to reconfigure and rebuild your system kernel to:

- Add a new device and its driver
- Reconfigure the High Performance Device Driver
- Remove a device and its driver
- Add or remove certain software packages
- Change the system memory size
- Add or change tunable parameters

You will use the kconfig utility to configure, build, and install a new kernel after you make any of the changes listed above. Refer to section 7 in the "INTERACTIVE UNIX Operating System Maintenance Procedures" to learn how to reconfigure and rebuild your system kernel.

14. ADMINISTERING SYSTEM SECURITY

Security deserves special consideration on a multi-user system. The information you have stored on your computer belongs to you and no one else. It is a valuable resource that requires protection. Three security features provided for your computer are:

- System backups
- Access permissions
- Passwords

14.1 Sources of Potential Damage

To provide adequate security for your system, you first need to consider the kinds of problems that might arise. It is important to consider every possible contingency: theft of the hardware, breakdowns in the hardware or software, tampering with data in the computer by unauthorized people, theft of data, and simple human error. To determine the types of problems to which your system may be vulnerable, ask yourself the following questions:

- Are you using your computer in a large or a small office? Is it possible for someone to steal your computer? Prevent theft by setting up your computer in a secure place.
- How many people have ready access to your system?
 Restrict the number of people with access to your computer by
 - Restrict the number of people with access to your computer by using passwords.

• How sensitive or valuable is the information you are storing? Restrict the number of people who have access to sensitive data using the access permissions.

• Do you transmit data over telephone lines? Limit access to your computer telephone numbers.

How you answer these questions will help you decide the measures you want to take to safeguard your data.

14.2 Basic Precautions

The following safeguards are recommended to everyone for ensuring the security of their computer and data:

- Set up your computer in an area that can be secured when you are not using it.
- Never leave your computer terminal logged in and unattended.
- If you are using your computer in an office environment, restrict the number of people who have access to the computer.

14.3 System Backups

If a breakdown occurs in the system, you may lose information that you had stored in the computer. You can avoid this type of loss if you have copies of your files stored on removable storage devices. Copy your data periodically onto diskettes or cartridge tapes and store them in a safe place, away from the computer site. Refer to section 12 for more information about the backup procedure.

14.4 Access Permissions

If you are sharing your computer with other users, you may want to share some information while keeping other information private. The INTERACTIVE UNIX Operating System allows you to satisfy both of these needs by letting you define:

- The users that have permission to access data
- The types of permission they have (that is, how they are allowed to use the data)

The INTERACTIVE UNIX System recognizes three categories of users of stored data: the owner of the data, the group to which the owner belongs, and all other people who use the system. Users can be given permission to use data in any or all of three ways: to read, write, and/or execute it. Refer to the "INTERACTIVE UNIX Operating System Primer" for more information about access permissions.

Whenever you create a file or directory, the system automatically identifies the users who will be allowed to read, write, and/or execute the file and the users who will be allowed to access the directory. As the owner of the file, only you and the superuser (usually the system administrator) can change the access permission after it has been created.

One way to restrict access to your files is to change the permission modes. Refer to the "INTERACTIVE UNIX Operating System

Primer," chmod(1), and ls(1) for more information about changing access permissions.

To keep people from looking at the contents of a directory, you can deny execute permission to that directory. Others will be prevented from listing or looking at the contents of your directory.

Whenever a file or directory is created, the permission modes are automatically set for everyone to have access, unless the umask command is set in your system profile or personal .profile. You can use the chmod command to change the permissions each time you create a file, or you can use the umask command to change the default permission modes of a file that you will be creating. Individual users can place the umask command in their .profile, or you can alter the system default profile, /etc/profile. Type:

umask *nnn*

nnn represents three octal digits that refer to read, write, and execute permission for owner, group, and other, respectively. The value of each permission digit is subtracted from the corresponding permissions digit. For example, if you add umask 022 to /etc/profile, all files normally created with 777 permission will now be created with 755 permissions. (umask 022 is set by default in /etc/profile in the INTERACTIVE UNIX Operating System.) A file created with 666 permissions will be created with 644 permissions. See umask(1) for additional information.

14.5 Password Administration

If you are at all worried about security, it is a good idea to force users to maintain passwords. When a login is first established, a password can be assigned, or one can be assigned later. The superuser can assign or change a password for any login. For more information about the password files and their management, refer to section 6, "MANAGING USER ACCOUNTS."

GLOSSARY

This glossary defines terms and acronyms used in this document that may not be familiar to you.

administrative login account

A login account used to give ordinary users restricted access to system management functions that must be performed frequently.

archival backup

A backup procedure that is used to back up all of the files and directories on a particular file system.

back up To copy files to removable media (such as a diskette or cartridge tape). A backup is the spare copy of data or software that you keep in case the original is damaged or lost. A backup may be incremental or archival. See incremental backup and archival backup.

baud rate

The speed at which a device that is connected to a tty line operates.

block files

Files that reside in /dev/dsk, which reference block devices, such as fixed disks, that access hardware one block (sector or record) at a time.

character files

Files that reside in /dev/rdsk, which reference character devices, such as terminals, which generally process data one character at a time.

configuration files

Files that store information that affects the environment of an individual user or affects the system on a global basis. Many INTERACTIVE UNIX System configuration files are shell command scripts or contain shell variable assignments.

console terminal

The console terminal is comprised of the screen and keyboard directly attached to the Central Processing Unit (CPU). It is important for the system administrator to use the console terminal since most error messages generated by the system are displayed on the console terminal screen.

- daemon A program that runs as a background process to handle UNIX System activities, for example, file transfers, command executions, and cleanup routines.
- *device* In the context of a computer system, a device is generally defined as a piece of hardware. For example, a diskette drive, a printer, or an on-board modem are all considered devices.

device driver

A software program associated with each specific device that is responsible for communicating between the hardware and the application program or operating system. It ensures that the device receives and carries out the instructions given by the user. Drivers for devices can be supplied with the operating system, with the application program, or by the manufacturer of the device.

environment variable

A word relating to the user's shell environment that is assigned a value and has a special meaning to the INTERACTIVE UNIX Operating System. For example, the default terminal type is a variable that is usually assigned a value for each user.

file system

A complete directory structure that is contained on a diskette or a fixed disk.

High Performance Device Driver

A set of integrated software packages that are part of the INTERACTIVE UNIX System kernel (also called the HPDD, for short). The HPDD allows several controllers to share a single driver, making it easier to add and use different types of controllers and significantly improves the speed of the system during most operations.

home directory

An area of the file system assigned to a user.

incremental backup

A backup procedure used to back up only those files and directories that have changed since the last complete backup.

mount point

The directory where a file system will be installed.

ordinary login account

Every user on the system uses an ordinary login account to perform most tasks. Ordinary logins include a login ID, a password, and an area of the file system assigned to the user, called a home directory.

partitions

The fixed disk is divided into sections called partitions. You may have only one partition that takes up the entire fixed disk, or you may have several partitions, each containing its own operating system, such as the UNIX System or DOS.

- reboot The procedure of bringing up the system.
- *restore* The procedure of copying the backup files from the removable media to the fixed disk.

root directory

The main (top level) directory in the root file system, which is automatically created and given the unique name of \prime (slash) when your system is installed and initialized.

root file system

The permanent file system established on the first subpartition of the INTERACTIVE UNIX System partition on the first fixed disk. It contains all of the important files and subdirectories that are required to run the INTERACTIVE UNIX Operating System.

root user

See superuser.

special files

Files that do not contain data. For example, device files are called special files because they are references to the actual programs that run the peripheral devices attached to your computer.

- spooler The term "spool" is an acronym for simultaneous peripheral operations on-line. The line printer spooling system allows you to send a file to be printed while you continue with other work.
- subtree A hierarchical arrangement of files and directories.
- string A word, file name, command, or other sequence of characters or letters.

superuser

The most privileged user on the system (also called the root user). There are no restrictions imposed upon root, which means that the person logged in to the system with the root ID can access, modify, and delete every file and process on the system.

swap area

An area of the disk used to store portions of programs or data that have been temporarily swapped out of main memory.

system administrator

The individual responsible for installing, administering, and maintaining your INTERACTIVE UNIX Operating System.

system dump

A procedure used by experienced system administrators to obtain detailed information about the state of the system when it crashed. (A system crash refers to the unexpected halting of the system due to hardware or software failure.)

system login account

Accounts used to perform system administration tasks that require privileged access to the restricted files and directories on the system. The two most important system logins are root and bin.

unmount

To deactivate (make inaccessible) the file system on a diskette or fixed disk.

utility A program. Related utilities can be combined into a package that represents a specific application available with your computer.

116

variable

This term usually refers to a shell environment variable. A variable is a word that is assigned a value and has a special meaning to the INTERACTIVE UNIX Operating System. For example, the default terminal type is a variable that is usually set for each user.
