

Tru64 UNIX

Network Administration

Part Number: AA-RH9CB-TE

August 2000

Product Version: Tru64 UNIX Version 5.1 or higher

This manual is intended for experienced system or network administrators. It describes the tasks for configuring your system to operate in a network, for configuring the network services, and for day-to-day management of the network, network interfaces, and network services. This manual also includes information for solving problems that might arise while using the network and network services.

Contents

About This Manual

Part 1 Management Information

1 Overview to Network Administration

1.1	Administrative Methods	1-2
1.1.1	SysMan Menu	1-2
1.1.1.1	Quick Setup	1-3
1.1.1.2	Network Wizard	1-5
1.1.1.3	Command-Line Integration	1-6
1.1.2	Compaq Insight Manager	1-7
1.1.3	Other Interfaces	1-8
1.1.4	Manually Editing Configuration Files	1-9
1.1.5	Installation and Configuration Cloning	1-9

2 Basic Network Connections

2.1	Network Environment	2-1
2.2	Preparing for the Configuration	2-2
2.2.1	Information for Interfaces and Daemons	2-2
2.2.1.1	All Network Interfaces	2-3
2.2.1.2	Token Ring Interface	2-6
2.2.1.3	NetRAIN Interface	2-6
2.2.1.4	rwhod Daemon	2-6
2.2.1.5	routed Daemon	2-7
2.2.1.6	Gateways File	2-8
2.2.1.7	gated Daemon	2-8
2.2.1.8	IP Router	2-9
2.2.2	Information for Network Files	2-9
2.2.2.1	Static Routes File (/etc/routes)	2-10
2.2.2.2	Hosts File (/etc/hosts)	2-11
2.2.2.3	Hosts Equivalencies File (/etc/hosts.equiv)	2-12
2.2.2.4	Networks File (/etc/networks)	2-12
2.3	Configuring the Network Components	2-12
2.3.1	Configuring Network Interfaces	2-13

2.3.2	Configuring the rwhod Daemon	2-15
2.3.3	Configuring the routed Daemon	2-16
2.3.4	Configuring the gated Daemon	2-17
2.3.5	Configuring the System as an IP Router	2-18
2.3.6	Configuring the Static Routes File	2-19
2.3.7	Configuring the hosts File	2-19
2.3.8	Configuring the hosts.equiv File	2-20
2.3.9	Configuring the networks File	2-21
2.3.10	Configuring IP Aliases	2-21
2.4	NetRAIN Interfaces	2-22
2.4.1	Configuring NetRAIN	2-22
2.4.1.1	Hardware Restrictions, Configuration, and Licensing	2-22
2.4.1.2	Configuring the NetRAIN Interface	2-24
2.4.2	Monitoring NetRAIN Activity	2-27
2.5	Configuring Multiple Network Interfaces in the Same Subnet	2-27
2.6	Enabling Access Filtering on an Interface	2-29
2.7	Monitoring the Local Host's Status	2-29
2.8	Displaying and Modifying the FDDI Parameters	2-30
2.9	Managing Token Ring Source Routing	2-32
2.10	Displaying and Modifying the Token Ring IP MTU Size	2-35
2.11	Managing Network Quality of Service	2-35
2.11.1	Managing the Traffic Control Subsystem	2-36
2.11.2	Managing RSVP	2-36
2.11.2.1	Starting and Stopping rsvpd	2-37
2.11.2.2	Adding and Deleting Network Interfaces	2-37
2.11.2.3	Displaying RSVP Session Information	2-37

3 Internet Protocol Version 6

3.1	Terms	3-2
3.2	IPv6 Addressing	3-2
3.2.1	Address Text Representation	3-2
3.2.2	Types of Addresses	3-3
3.2.2.1	Unicast Address	3-4
3.2.2.2	Multicast Address	3-7
3.2.3	Address Prefixes	3-8
3.2.4	Address Autoconfiguration	3-8
3.2.5	Address Resolution	3-9
3.2.6	Address Assignment	3-10
3.2.6.1	Aggregatable Global Unicast Address Format	3-10
3.2.6.2	Aggregatable Testing Address Format	3-11
3.3	IPv6 Environment	3-12

3.4	Planning IPv6	3-16
3.4.1	Verifying IPv6 Support in the Kernel	3-16
3.4.2	Preparing for the Configuration	3-17
3.4.2.1	DNS/BIND	3-20
3.4.2.2	Configured Tunnel	3-20
3.4.2.3	Router	3-21
3.4.2.4	Manual Routes	3-21
3.4.3	Configuring Systems in Sample IPv6 Configurations	3-22
3.4.3.1	Simple Host-to-Host Configuration	3-22
3.4.3.2	Host-to-Host with Router Configuration	3-22
3.4.3.3	IPv6 Network-to-IPv6 Network with Router Configuration	3-23
3.4.3.4	Multiple IPv6 Networks and Multiple Routers Configuration	3-24
3.4.3.5	Host-to-Host over Tunnel Configuration	3-25
3.4.3.6	Host-to-Router over Tunnel Configuration	3-25
3.4.3.7	IPv6 Network-to-IPv6 Network over Tunnel Configuration	3-27
3.5	Configuring IPv6 on Your System	3-28
3.5.1	Configuring an IPv6 Host	3-29
3.5.2	Configuring an IPv6 Router	3-30
3.6	Postconfiguration Tasks	3-33
3.6.1	Connecting to the 6bone Network	3-33
3.6.2	Initializing a New Interface for IPv6	3-34
3.6.2.1	Setting the IPv6 Interface Identifier	3-34
3.6.3	Removing IPv6 from an Interface	3-35
3.6.4	Creating a Configured Tunnel	3-35
3.6.5	Adding an Address to an Interface	3-35
3.6.6	Deleting an Address from an Interface	3-36
3.6.7	Adding or Deleting a Default Router	3-36
3.6.8	Manually Adding a Route for an Onlink Prefix	3-36
3.6.9	Configuring Routing Support in the Kernel	3-37
3.6.10	Editing the Run-time Configuration File	3-37
3.6.11	Editing the Router Configuration File	3-39
3.6.12	Tuning the Kernel Subsystems	3-40
3.7	IPv6 Daemon Log Files	3-40

4 Asynchronous Transfer Mode

4.1	ATM Environment	4-1
4.1.1	Classical IP Environment	4-2
4.1.2	LAN Emulation Environment	4-3

4.1.3	IP Switching	4-4
4.2	Planning ATM	4-6
4.2.1	Verifying That the ATM Subsets Are Installed	4-6
4.2.2	Configuring ATM into the Kernel	4-6
4.2.3	Preparing for the Configuration	4-7
4.2.3.1	Adapter Information	4-7
4.2.3.2	Classical IP Information	4-9
4.2.3.3	LAN Emulation Information	4-11
4.2.3.4	IP Switching Information	4-13
4.3	Configuring ATM	4-15
4.3.1	Configuring an ATM Adapter	4-16
4.3.2	Configuring Classical IP	4-17
4.3.2.1	Creating PVC Mappings on Your ATM Switch	4-17
4.3.2.2	Adding Servers to the atmhosts File	4-17
4.3.2.3	Adding Hosts to the hosts Database	4-18
4.3.2.4	Running the ATM Configuration Application	4-19
4.3.2.5	Configuring the Classical IP Logical Interface	4-20
4.3.2.6	Adding Static Routes (SVC only)	4-20
4.3.2.7	Verifying the PVC Configuration (PVCs only)	4-20
4.3.3	Configuring LAN Emulation	4-20
4.3.3.1	Adding Servers to the atmhosts File	4-21
4.3.3.2	Adding Hosts to the hosts Database	4-21
4.3.3.3	Running the ATM Configuration Application	4-21
4.3.3.4	Configuring the LAN Emulation Logical Interfaces ...	4-22
4.3.4	Configuring IP Switching	4-22
4.3.4.1	Adding IP Addresses to the hosts File	4-23
4.3.4.2	Running the ATM Configuration Application	4-23
4.3.4.3	Configuring the IP Switching Logical Interfaces	4-25
4.3.4.4	Adding Routes	4-25
4.4	Managing the ATM Environment	4-25
4.4.1	ATM Networking and Displaying Information About ATM Networks	4-26
4.4.2	The Signaling Module	4-26
4.4.3	The Classical IP Environment	4-26
4.4.4	The LAN Emulation Environment	4-27
4.4.4.1	Managing LAN Emulation Clients	4-27
4.4.4.2	Displaying the LE-ARP Table	4-27
4.4.5	IP Switching	4-27
4.4.6	ATM Subsystem Messages	4-28

5 Dynamic Host Configuration Protocol

5.1	DHCP Environment	5-2
-----	------------------------	-----

5.1.1	DHCP Parameter Assignment	5-2
5.1.2	DHCP and Security	5-3
5.2	Planning DHCP	5-4
5.2.1	Verifying Installation of the DHCP Software	5-4
5.2.2	Preparing for the Configuration	5-4
5.2.2.1	Server/Security Parameters	5-4
5.2.2.2	Information for Basic DHCP Parameters	5-8
5.3	Configuring a DHCP Server	5-12
5.3.1	Configuring Server/Security Parameters	5-13
5.3.2	Configuring IP Ranges	5-13
5.3.3	Configuring Host Name Lists	5-13
5.3.4	Configuring a Subnetwork	5-14
5.3.5	Configuring a DHCP Client Node	5-14
5.3.6	Setting Group Parameters	5-16
5.4	Starting the DHCP Server (joind)	5-16
5.5	Starting the DHCP Client	5-17
5.6	Monitoring DHCP Client Configuration	5-18
5.7	Mapping Client IP Addresses Permanently	5-18
5.8	Restricting Access to the DHCP Server	5-19
5.9	Configuring a BOOTP Client	5-19
5.10	Disabling DHCP Address Assignment	5-20

6 Point-to-Point Connections

6.1	Serial Line Internet Protocol (SLIP)	6-1
6.1.1	SLIP Environment	6-1
6.1.2	Planning SLIP	6-2
6.1.2.1	Verifying the Hardware	6-3
6.1.2.2	Preparing for the Configuration	6-4
6.1.3	Configuring SLIP	6-7
6.1.3.1	Configuring a Dial-In System	6-8
6.1.3.2	Configuring a Dial-Out System	6-9
6.1.4	Terminating a SLIP Dial-Out Connection	6-10
6.2	Point-to-Point Protocol (PPP)	6-11
6.2.1	PPP Environment	6-11
6.2.1.1	Chat Scripts	6-12
6.2.1.2	PPP Options	6-13
6.2.1.3	Authentication	6-14
6.2.2	Planning PPP	6-15
6.2.2.1	Verifying the Hardware	6-15
6.2.2.2	Verifying PPP Support in the Kernel	6-16
6.2.2.3	Preparing for Configuration	6-16

6.2.3	Configuring a Dial-Out System with PPP	6-19
6.2.3.1	Setting Up Initial Communications for a Dial-Out System	6-19
6.2.3.2	Creating Options Files for a Dial-Out System	6-20
6.2.3.3	Setting Up Authentication for a Dial-Out System	6-21
6.2.3.3.1	Creating Entries in the PAP Secrets File	6-21
6.2.3.3.2	Creating Entries in the CHAP Secrets File	6-22
6.2.3.4	Setting Up Message Logging	6-22
6.2.3.5	Initiating and Monitoring a PPP Connection	6-23
6.2.3.6	Connecting to a Microsoft NT Remote Access Server ..	6-23
6.2.3.6.1	Configuring an NT RAS Server	6-24
6.2.3.6.2	Solving Microsoft CHAP Authentication Problems	6-25
6.2.4	Configuring a Dial-In System with PPP	6-25
6.2.4.1	Setting Up Initial Communications for a Dial-In System	6-25
6.2.4.2	Creating Options Files for a Dial-In System	6-26
6.2.5	Terminating PPP Connections	6-27
6.3	Guidelines for Using Modems	6-27
6.3.1	Using the Correct Modem Cables	6-27
6.3.2	Configuring a System for Dial-In Access	6-28
6.3.2.1	Setting Up a Modem for Dial-In Access	6-29
6.3.3	Configuring Your System for Dial-Out Access	6-31
6.3.3.1	Creating Entries in the /etc/remote File	6-32

7 Local Area Transport Connections

7.1	LAT Environment	7-1
7.1.1	Types of LAT Connections	7-2
7.1.2	Controlling Access in a LAT Network	7-3
7.1.3	Specifying Passwords for Remote Services	7-4
7.1.4	Load Balancing	7-4
7.2	Planning LAT	7-4
7.2.1	Verifying That the LAT Subset Is Installed	7-4
7.2.2	Verifying DLB Support in the Kernel	7-4
7.2.3	Preparing for the Configuration	7-5
7.3	Configuring LAT	7-6
7.4	Starting and Stopping LAT	7-7
7.5	Creating a LAT Startup File	7-7
7.6	Customizing the inittab File	7-9
7.7	Running LAT Over Specific Network Adapters	7-10
7.8	Setting Up Printers	7-10
7.8.1	Setting Up the Printer on a Terminal Server	7-11

7.8.2	Testing the Port Configuration	7-12
7.8.3	Setting Up a Service Node for the Printer	7-12
7.8.4	Setting Up the Print Spooler on the Service Node	7-12
7.8.5	Testing the Printer	7-13
7.9	Setting Up Host-Initiated Connections	7-13
7.9.1	Setting Up the System for Host-Initiated Connections	7-13
7.9.2	Program Interface	7-14
7.10	Setting Up Outgoing Connections	7-14
7.10.1	Setting Up the System for Outgoing Connections	7-15
7.10.2	Program Interface	7-15
7.11	Setting Up the LAT/Telnet Gateway	7-15
7.12	Creating Dedicated or Optional Services	7-17
7.13	Providing a Dedicated tty Device on a Terminal	7-18
7.13.1	Setting Up a Dedicated tty Device	7-18
7.13.2	Removing a Dedicated tty Device	7-19

8 Domain Name System

8.1	DNS Environment	8-1
8.2	Dynamic Updates	8-5
8.3	Authentication of Dynamic Updates and Zone Transfers	8-6
8.4	Planning DNS	8-6
8.4.1	Server	8-7
8.4.2	Client	8-9
8.5	Configuring DNS	8-9
8.5.1	Configuring a Master Server	8-9
8.5.1.1	Configuring an IPv6 Master Server	8-11
8.5.1.1.1	DNS Configuration Files	8-11
8.5.1.1.2	Server Guidelines	8-11
8.5.1.2	Enabling Dynamic Updates to the DNS Database	8-12
8.5.2	Configuring a Slave Server	8-13
8.5.3	Configuring a Caching-Only Server	8-15
8.5.4	Configuring a Forward-Only Server	8-16
8.5.5	Configuring a Stub Server	8-18
8.5.6	Configuring a DNS Client	8-20
8.6	Configuring Authentication	8-21
8.6.1	Configuring Secure Dynamic Updates	8-22
8.6.2	Configuring Secure Zone Transfers	8-24
8.6.3	Authentication Example	8-26
8.7	Deconfiguring DNS	8-29
8.8	Modifying the svc.conf File with svcsetup	8-30
8.9	Updating DNS Data Files on the Master Server	8-30

8.10	Obtaining Host Name and IP Address Information	8-31
8.10.1	The nslookup Command	8-31
8.10.2	NIC whois Service	8-32

9 Network Information Service

9.1	NIS Environment	9-1
9.2	Planning NIS	9-3
9.2.1	Verifying That the Additional Networking Services Subset is Installed	9-3
9.2.2	Preparing for the Configuration	9-3
9.2.2.1	Master Server	9-5
9.2.2.2	Slave Server	9-7
9.2.2.3	Client	9-9
9.3	Configuring NIS	9-10
9.3.1	Configuring an NIS Master Server	9-11
9.3.2	Configuring a Slave Server	9-15
9.3.3	Configuring an NIS Client	9-17
9.3.4	Modifying the svc.conf File with svcsetup	9-19
9.3.5	Modifying or Removing an NIS Configuration	9-20
9.4	Managing an NIS Server	9-20
9.4.1	Adding an NIS Slave Server to a Domain	9-20
9.4.2	Removing an NIS Slave Server from the Domain	9-22
9.4.3	Adding a New User to an NIS Domain	9-23
9.4.4	Adding a New Group to an NIS Domain	9-25
9.4.5	Updating an NIS Map	9-25
9.4.6	Adding an NIS Map to a Domain	9-26
9.4.7	Removing an NIS Map from a Domain	9-27
9.4.8	Modifying the /var/yp/Makefile File	9-28
9.4.8.1	Adding an Entry	9-28
9.4.8.2	Deleting an Entry	9-29
9.4.9	Restricting Access to NIS Data	9-29
9.5	Managing an NIS Client	9-31
9.5.1	Changing an NIS Password	9-31
9.5.2	Obtaining NIS Map Information	9-31

10 Network File System

10.1	NFS Environment	10-1
10.1.1	Distributing the hosts Database	10-1
10.1.2	Automatic Mounting Daemons	10-2
10.1.2.1	Serving Automount and AutoFS Maps with NIS	10-2
10.1.2.2	Local Automount and AutoFS Maps	10-2

10.1.2.3	WebNFS	10-3
10.2	Planning NFS	10-3
10.2.1	Server	10-4
10.2.1.1	Exported Directories	10-5
10.2.2	Client	10-6
10.2.2.1	Imported Directories	10-7
10.3	Configuring NFS	10-8
10.3.1	Configuring an NFS Server	10-8
10.3.2	Configuring an NFS Client	10-9
10.4	Deconfiguring NFS	10-10
10.5	Managing an NFS Server	10-11
10.5.1	Export Guidelines	10-11
10.5.2	Exporting a File System or Directory	10-12
10.5.3	Halting Export of a Directory or File System	10-13
10.5.4	Enabling Client Superuser Access to Files	10-13
10.5.5	Sending Mail to Superuser (root) Across NFS	10-14
10.5.6	Enabling Port Monitoring	10-16
10.5.7	Monitoring the NFS Load	10-16
10.6	Managing an NFS Client	10-17
10.6.1	Mounting a Remote File System or Directory	10-17
10.6.2	Automatically Mounting a Remote File System	10-19
10.6.2.1	Using Automount to Mount a Remote File System	10-19
10.6.2.2	Using AutoFS to Mount a Remote File System	10-20
10.6.2.3	Specifying automount and autofsmount Arguments ...	10-22
10.6.3	Unmounting a Remote File System or Directory	10-24

11 UNIX-to-UNIX Copy Program

11.1	UUCP Environment	11-1
11.2	Planning UUCP	11-2
11.2.1	Verifying the Correct Hardware	11-2
11.2.2	Preparing for the Configuration	11-3
11.2.2.1	Information for Connections	11-3
11.2.2.2	Information for Outgoing Systems	11-6
11.2.2.3	Information for Incoming Systems	11-9
11.3	Configuring UUCP	11-12
11.3.1	Configuring Connections	11-12
11.3.2	Configuring Outgoing Systems	11-13
11.3.3	Configuring Incoming Systems	11-14
11.3.4	Configuring the Poll File	11-15
11.3.5	Configuring the uucico Daemon	11-15
11.4	Monitoring the File Transfer Queue	11-16

11.4.1	Getting Queue Status Manually	11-17
11.4.2	Getting Queue Status Automatically	11-17
11.4.3	Guidelines for Checking Queue Status	11-18
11.5	Cleaning Up the Spooling Directories	11-18
11.5.1	Cleaning Up Directories Manually	11-19
11.5.2	Cleaning Up Directories Automatically	11-20
11.5.3	Guidelines for Removing Files	11-21
11.6	Viewing Log Files	11-21
11.7	Cleaning Up sulog and cron/log Files	11-22
11.8	Limiting the Number of Remote Executions	11-23
11.9	Scheduling Work in the Spooling Directory	11-23
11.9.1	Starting uusched Manually	11-23
11.9.2	Starting uusched Automatically	11-23
11.10	Calling File Transfer Programs (uudemon.hour)	11-24
11.11	Polling Remote Systems (uudemon.poll)	11-25

12 Network Time Protocol

12.1	NTP Environment	12-2
12.2	Planning NTP	12-3
12.2.1	Server Information	12-4
12.2.2	Client Information	12-5
12.3	Configuring NTP	12-6
12.4	Enabling the High-Resolution Clock	12-8
12.5	Monitoring Hosts Running the xntpd Daemon	12-8
12.6	Querying Servers Running NTP	12-10

13 Mail System

13.1	Mail Environment	13-1
13.1.1	Directing Outgoing Mail to Servers	13-5
13.1.2	Handling Incoming Mail to the Domain	13-5
13.1.3	Delivering Mail to Clients	13-5
13.1.4	Distributing the aliases File	13-6
13.1.5	Distributing the passwd File	13-6
13.1.6	Handling DECnet Mail	13-6
13.2	Planning Mail	13-8
13.2.1	Verifying that Required Protocols are Installed	13-8
13.2.2	Verifying that Required Services are Configured	13-8
13.2.3	Preparing for the Configuration	13-9
13.2.3.1	General System Information	13-9
13.2.3.2	Protocol Information	13-10
13.3	Configuring Mail	13-13

13.3.1	Configuring a Standalone Mail System	13-14
13.3.2	Configuring a Mail Client	13-15
13.3.3	Configuring a Mail Server	13-16
13.3.4	Adding a New Mail Host	13-18
13.4	Post Office Protocol	13-18
13.4.1	Installing POP	13-18
13.4.2	Migrating to the New POP3 Implementation	13-19
13.4.2.1	Migrating from MH POP3	13-19
13.4.2.2	Migrating from Qualcomm POP3	13-20
13.4.3	Configuring a POP Mail Account	13-20
13.4.4	Changing Login Authentication	13-21
13.4.5	Administrative Tools	13-22
13.4.6	Directory Structure	13-23
13.5	Internet Message Access Protocol	13-24
13.5.1	Installing IMAP	13-24
13.5.2	Upgrading IMAP	13-25
13.5.3	Configuring IMAP Mail Accounts	13-25
13.5.4	Migrating Users from UNIX and POP3 Mail	13-27
13.5.5	Administrative Tools	13-28
13.5.6	Directory Structure	13-29
13.5.7	Mailbox Namespace	13-32
13.5.8	Access Control Lists	13-33
13.5.9	Quotas	13-35

About This Manual

This manual describes how to configure and manage the network interfaces and network services, and solve problems that might arise on systems running the Tru64™ UNIX (formerly DIGITAL UNIX) operating system software.

This manual assumes that the operating system software and the appropriate networking subsets are installed.

Audience

This manual is intended for system and network administrators responsible for configuring and managing network services. Administrators are expected to have knowledge of operating system concepts, commands, and configuration. It is also helpful to have knowledge of Transmission Control Protocol/Internet Protocol (TCP/IP) networking concepts and network configuration; this manual is not a TCP/IP networking tutorial.

New and Changed Features

This manual has been revised to include the following:

- An expanded overview of administrative methods
- A new chapter on Internet Protocol Version 6 (IPv6), originally part of the *Guide to Tru64 UNIX IPv6*, a new section on configuring an IPv6 Domain Name System (DNS) master server, and updated sections throughout the manual to discuss where IPv6 is supported
- New sections on configuring authentication of DNS dynamic updates and zone transfers
- New and updated sections about automatically and transparently mounting remote file systems with the AutoFS daemon
- An updated section on IMAP mail to discuss changes related to its directory structure
- An updated section on administering and distributing alias information that describes new Sendmail support for LDAP servers
- Updated sections throughout the manual on how to use the SysMan Menu to configure network components
- Updated sections on problem solving tools

- Information that was previously included in the *Release Notes*

Organization

This manual is divided into two parts and several appendices. Part 1, Chapters 1–14, contains management information and Part 2, Chapters 15–18, contains problem solving information. The appendices contain supplemental information.

The following list describes the contents of each chapter and appendix in more detail:

<i>Chapter 1</i>	Describes the meaning of network administration and the components covered in this manual
<i>Chapter 2</i>	Describes the tasks to administer the basic network connections
<i>Chapter 3</i>	Describes the tasks to administer Internet Protocol Version 6 (IPv6) networks
<i>Chapter 4</i>	Describes the tasks to administer an Asynchronous Transfer Mode (ATM) network adapter
<i>Chapter 5</i>	Describes the tasks to administer the Dynamic Host Configuration Protocol (DHCP)
<i>Chapter 6</i>	Describes the tasks to administer point-to-point connections
<i>Chapter 7</i>	Describes the tasks to administer Local Area Transport (LAT)
<i>Chapter 8</i>	Describes the tasks to administer the Domain Name System (DNS)
<i>Chapter 9</i>	Describes the tasks to administer the Network Information Service (NIS)
<i>Chapter 10</i>	Describes the tasks to administer the Network File System (NFS)
<i>Chapter 11</i>	Describes the tasks to administer the UNIX-to-UNIX Copy Program (UUCP)
<i>Chapter 12</i>	Describes the tasks to administer the Network Time Protocol (NTP)
<i>Chapter 13</i>	Describes the tasks to administer the mail environment
<i>Chapter 14</i>	Describes the Simple Network Management Protocol (SNMP)
<i>Chapter 15</i>	Describes how to diagnose network and network service problems
<i>Chapter 16</i>	Describes the various diagnostic tests available to help solve problems
<i>Chapter 17</i>	Describes how to test DNS servers and resolve DNS server problems

<i>Chapter 18</i>	Describes how to report your problem to Compaq and the information you need to provide
<i>Appendix A</i>	Describes how to monitor the Ethernet, Fiber Distributed Data Interface (FDDI), and token ring network interfaces by using the <code>netstat</code> command
<i>Appendix B</i>	Describes how to write Automount and AutoFS maps
<i>Appendix C</i>	Contains two scripts you can copy for adding NIS slave servers to and removing NIS slave servers from an NIS domain
<i>Appendix D</i>	Contains NFS error messages and describes possible solutions
<i>Appendix E</i>	Contains <code>uucp</code> error messages and describes possible solutions
<i>Appendix F</i>	Contains <code>sendmail</code> error messages and describes possible solutions
<i>Appendix G</i>	Describes the Tru64 UNIX host MIB implementation, including sample data
<i>Appendix H</i>	Describes the format of DNS file entries

Related Documents

For more information about Tru64 UNIX networking and communications, see the following books:

- *BIND Configuration File Guide*
Provides information about how to manually create and edit the `named.conf` configuration file on systems that use the DNS/BIND for address resolution. This document is available in HTML format on the Tru64 UNIX Documentation CD-ROM.
- *Command and Shell User's Guide*
Introduces users to the basic uses of commands and shells in the operating system.
- *JOIN Server Administrator's Guide* by Join Systems, Inc.
Provides more detailed information about implementing the Dynamic Host Configuration Protocol in your network. This document can be accessed by opening the following file with a web browser:
`/usr/doc/join/TOC.html`
- *Sendmail Installation and Operation Guide*
Provides additional information about using the `sendmail` command. This document is available in PDF format on the Tru64 UNIX Documentation CD-ROM.
- The *sendmail* guide by O'Reilly & Associates

Provides additional information about using the `sendmail` command.

- Request for Comments (RFC)

Many sections of this book refer to RFCs (for example, RFC 1577) for more information about certain networking topics. These documents publicize Internet Standards, new research concepts, and status memos about the internet. You can access the full range of RFC documents and more information about the Internet Engineering Task Force (IETF) at the following URL:

<http://www.ietf.org>

- Best Practices

Compaq Tru64 UNIX Best Practices describe additional concepts and tasks, for networking as well as other topics. You can find these documents at the following URL:

http://www.tru64unix.compaq.com/faqs/publications/best_practices

Icons on Tru64 UNIX Printed Books

The printed version of the Tru64 UNIX documentation uses letter icons on the spines of the books to help specific audiences quickly find the books that meet their needs. (You can order the printed documentation from Compaq.) The following list describes this convention:

- G Books for general users
- S Books for system and network administrators
- P Books for programmers
- D Books for device driver writers
- R Books for reference page users

Some books in the documentation help meet the needs of several audiences. For example, the information in some system books is also used by programmers. Keep this in mind when searching for information on specific topics.

The *Documentation Overview* provides information on all of the books in the Tru64 UNIX documentation set.

Reader's Comments

Compaq welcomes any comments and suggestions you have on this and other Tru64 UNIX manuals.

You can send your comments in the following ways:

- **Fax:** 603-884-0120 Attn: UBPG Publications, ZKO3-3/Y32
- **Internet electronic mail:** readers_comment@zk3.dec.com

A Reader's Comment form is located on your system in the following location:

`/usr/doc/readers_comment.txt`

- **Mail:**

Compaq Computer Corporation
UBPG Publications Manager
ZKO3-3/Y32
110 Spit Brook Road
Nashua, NH 03062-2698

A Reader's Comment form is located in the back of each printed manual. The form is postage paid if you mail it in the United States.

Please include the following information along with your comments:

- The full title of the book and the order number. (The order number is printed on the title page of this book and on its back cover.)
- The section numbers and page numbers of the information on which you are commenting.
- The version of Tru64 UNIX that you are using.
- If known, the type of processor that is running the Tru64 UNIX software.

The Tru64 UNIX Publications group cannot respond to system problems or technical support inquiries. Please address technical questions to your local system vendor or to the appropriate Compaq technical support office. Information provided with the software media explains how to send problem reports to Compaq.

Conventions

This document uses the following typographic conventions:

%

\$

A percent sign represents the C shell system prompt.
A dollar sign represents the system prompt for the Bourne, Korn, and POSIX shells.

#

A number sign represents the superuser prompt.

% **cat**

Boldface type in interactive examples indicates typed user input.

file

Italic (slanted) type indicates variable values, placeholders, and function argument names.

[|]

{ | }

In syntax definitions, brackets indicate items that are optional and braces indicate items that are required. Vertical bars separating items inside brackets or braces indicate that you choose one item from among those listed.

...

In syntax definitions, a horizontal ellipsis indicates that the preceding item can be repeated one or more times.

cat(1)

A cross-reference to a reference page includes the appropriate section number in parentheses. For example, `cat(1)` indicates that you can find information on the `cat` command in Section 1 of the reference pages.

Return

In an example, a key name enclosed in a box indicates that you press that key.

Ctrl/*x*

This symbol indicates that you hold down the first named key while pressing the key or mouse button that follows the slash. In examples, this key combination is enclosed in a box (for example, Ctrl/C).

Part 1

Management Information

Overview to Network Administration

Network administration comprises those tasks that deal with setting up and configuring network interfaces, software, and daemons, and those tasks that deal with the day-to-day management of those interfaces, software, and daemons, including solving problems that might arise.

This manual describes the administration of the following:

- Basic network connections, including Ethernet, Token Ring, and Fiber Distributed Data Interface (FDDI) interfaces, automatic network adapter failover (NetRAIN), and network daemons
- Internet Protocol Version 6 (IPv6)
- Asynchronous Transfer Mode (ATM)
- Dynamic Host Configuration Protocol (DHCP)
- Point-to-point connections, including Serial Line Internet Protocol (SLIP) and Point-to-Point Protocol (PPP)
- Local Area Transport (LAT)
- Domain Name System (DNS)
- Network Information Service (NIS), formerly named Yellow Pages
- Network File System (NFS)
- UNIX-to-UNIX Copy Program (UUCP)
- Network Time Protocol (NTP)
- Mail environment
- Simple Network Management Protocol (SNMP)

Day-to-day management varies with each network service, as each one provides different capabilities. Typically, management involves making small changes and adjustments, such as adding user accounts, mounting remote file systems or directories, obtaining status information, and setting up automatic maintenance scripts. Each chapter in Part 1 of this book describes a specific task, presenting the generic steps required to perform the task followed by examples and additional information.

In addition to the day-to-day management of the network and network services, this manual contains information to help you solve problems that

might occur. Problem solving is handled as a separate part of administration because it is not something that you have to do every day.

Unlike the administration chapters, problem-solving chapters are structured according to specific problems. Within each problem section are the steps to resolve the problem.

The key to successful problem solving is in isolating the source of the problem. Frequently, complex networks and interactions between network services make this difficult to do. If you encounter a problem, whether by error message or event (for example, slow response), do the following:

1. Check your system, its network interface, and connections to the network.
2. Check the network and your system's ability to reach a remote system.

Most problems can be solved after you perform these two steps. If not, go to the appropriate problem-solving section and follow the steps.

1.1 Administrative Methods

The following sections provide a brief overview of the methods for administering networking components in the operating system. As explained in Section 1.1.4, it is best to not to edit configuration files manually for network configuration tasks. Instead, it is highly recommended that you use the SysMan Menu utility whenever possible.

1.1.1 SysMan Menu

The SysMan Menu utility enables you to administer your system locally via a graphical user interface or command-line interface, or even remotely via the World Wide Web. It provides a single, hierarchical menu interface that allows you to quickly find and invoke suitlets (integrated utilities) to perform the most common management tasks.

In this manual, wherever the SysMan Menu utility is mentioned in relation to configuration tasks, it is presumed that you know how to invoke it. To invoke the SysMan Menu utility from CDE, do the following:

1. Select the Application Manager icon on the CDE front panel.
2. Select the System_Admin application group icon.
3. Select the SysMan Menu. The SysMan Menu is displayed and lists various system management tasks.

If you are not using CDE, you can invoke the SysMan Menu in one of the following ways:

```
# /usr/sbin/sysman
```

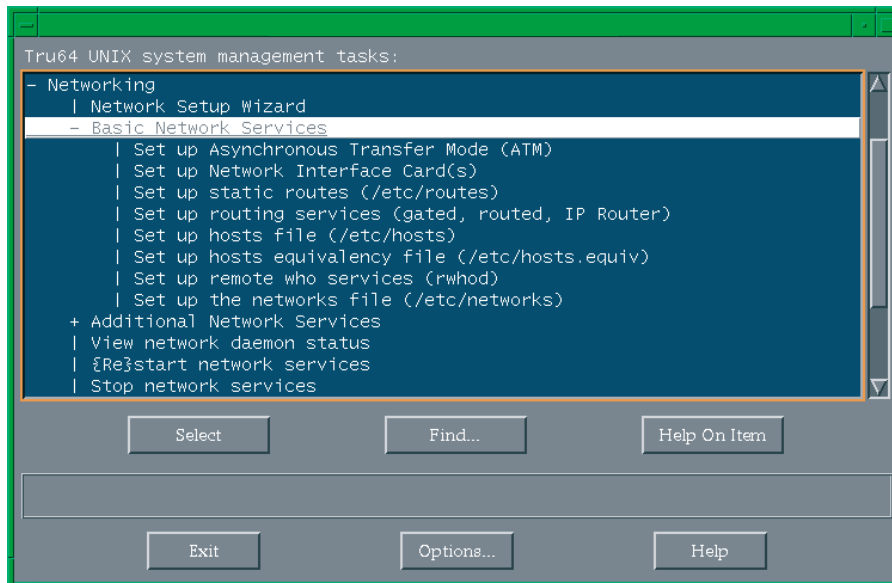

From a character-cell terminal or terminal window, for curses mode, enter:

```
# sysman -ui cui
```

Once you invoke the SysMan Menu, double-click on menu items to select them. Or, on a system without graphics capabilities, use the arrow keys and the Enter key to select items. Many menu items will expand to offer more choices. Navigate the menu until you find the desired suitlet.

In Figure 1–1, the user selects the Basic Network Services menu item, which expands to reveal the suitlets for configuring network adapters and other basic networking components.

Figure 1–1: SysMan Menu

To exit the SysMan Menu, select Exit. On a system without graphics capabilities, use the Tab key to move the cursor to Exit, then press the Enter key.

For more information about the SysMan Menu, see the *System Administration* manual, `sysman(8)`, and the online help.

1.1.1.1 Quick Setup

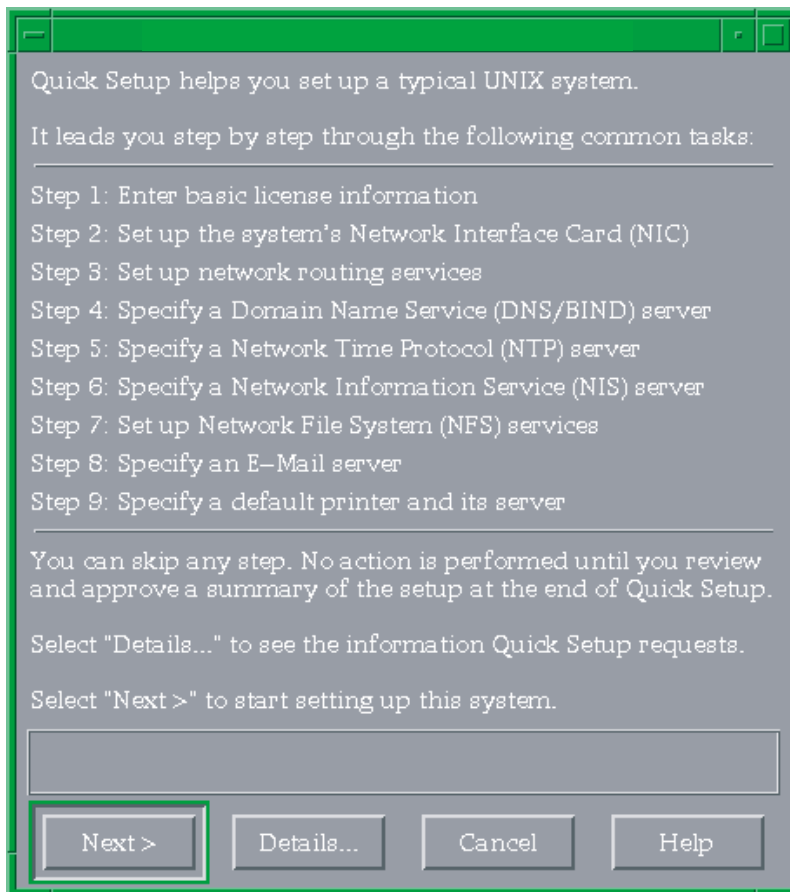

The SysMan Menu includes a Quick Setup utility that you can use to configure basic components and services on a client system. The Quick Setup utility starts automatically when the system boots following a full

installation of the operating system. However, to use the utility at any time, invoke the SysMan Menu and select General Tasks→Quick Setup, or enter the following command on a command line:

```
# /usr/bin/sysman quicksetup
```

The Quick Setup utility, as shown in Figure 1–2, is displayed.

Figure 1–2: Quick Setup

The utility leads you through the displayed configuration steps, many of which prepare your system for operation on a network. Enter the information for each step of the process and select Next to display the subsequent step. You can move back and forth through the steps if you have missed something. No information is saved until you confirm the configuration by selecting Finish in the last step.

If necessary, you can configure additional components or modify your configuration after you use the utility. For more information about the Quick Setup utility, see the online help.

1.1.1.2 Network Wizard

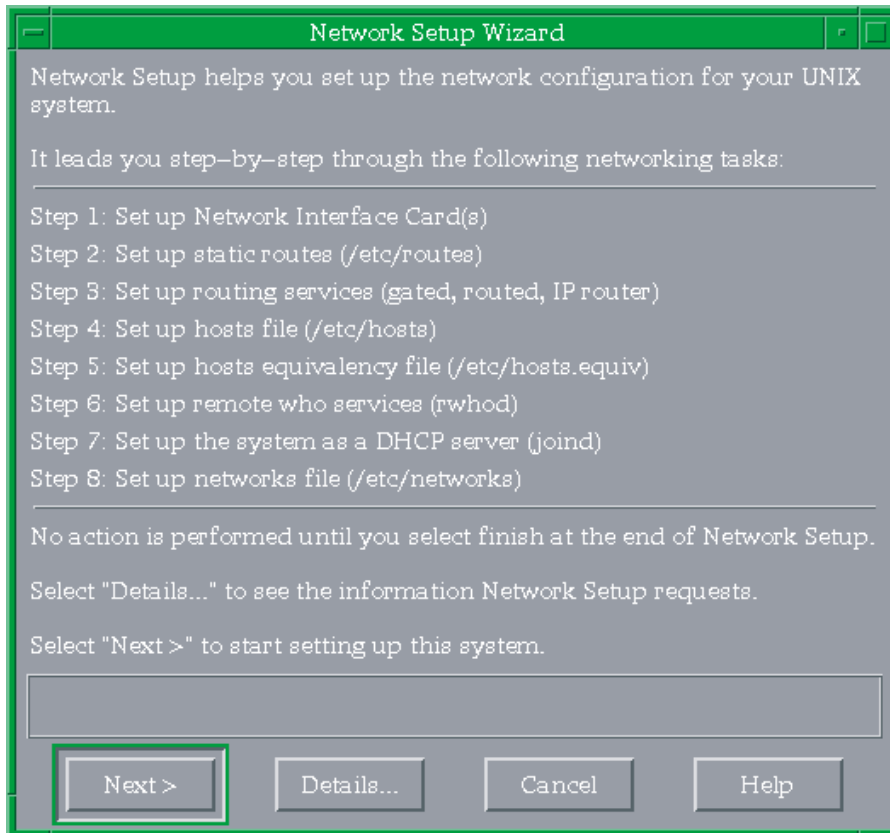

The SysMan Menu also includes a Network Wizard utility that you can use to configure network components on your system. As discussed in Section 2.3, you can invoke the configuration suitlets through the SysMan Menu to configure basic network services on an individual basis, or you can use the Network Setup Wizard, which leads you step-by-step through the setup process for all of the basic network services.

To use the Network Wizard, invoke the SysMan Menu and select Networking→Network Setup Wizard, or enter the following command on a command line:

```
# /usr/bin/sysman net_wizard
```

The Network Wizard utility, as shown in Figure 1–3, is displayed.

Figure 1–3: Network Wizard

The utility leads you through the displayed configuration steps. Enter the information for each step of the process and select Next to display the subsequent step. You can move back and forth through the steps if you have missed something. No information is saved until you confirm the configuration by selecting Finish in the last step.

If necessary, you can configure additional components or modify your configuration after you use the utility. For more information about the Network Wizard utility, see the online help.

1.1.1.3 Command-Line Integration

The SysMan Menu allows you to access and manipulate many configuration options directly from the command line. This feature is particularly useful for administrators who want to create site-specific shell scripts to perform configuration tasks.

To use the command-line interface, invoke the `sysman -cli` command. For the command's arguments, specify the component and group on which you want to operate and the action you want to perform.

For example, suppose you want to list all of the entries in the `/etc/hosts` file. You would enter the following command:

```
# sysman -cli -list val -comp networkedSystems \  
-group hostMappings
```

You could also add a host to the file by entering this command:

```
# sysman -cli -add row -comp networkedSystems \  
-group hostMappings -data "{queen} \  
{DNS server} {18.240.32.40} {queen.abc.xyz.com}"
```

You can even change an existing value in the file, like an IP address, as follows:

```
# sysman -cli -set val -comp networkedSystems \  
-group hostMappings -attr networkAddress="18.240.32.45" \  
-key1 queen.abc.xyz.com -key2 18.240.32.40
```

For more information about this command line interface for the SysMan Menu, see the *System Administration* guide and `sysman_cli(8)`.

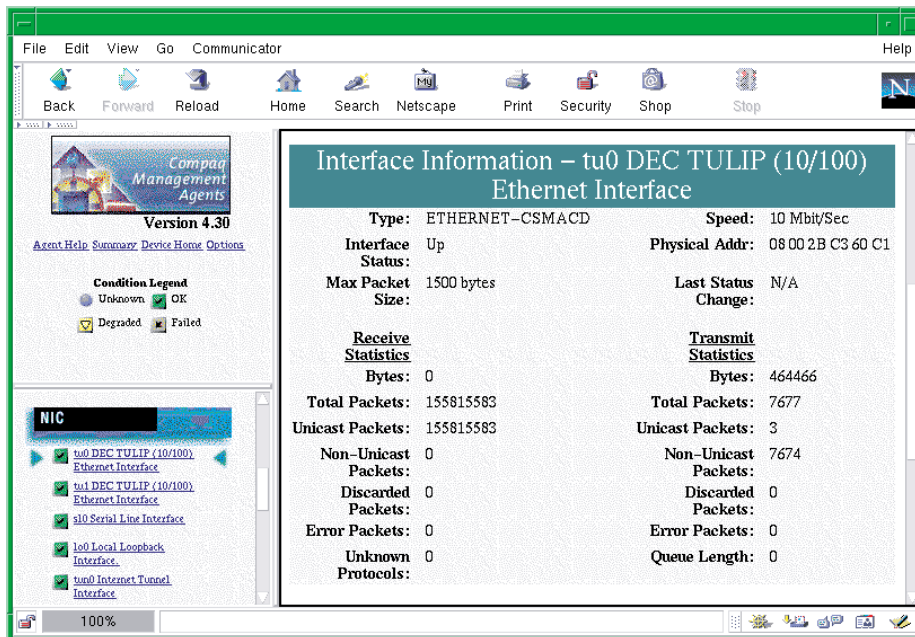

1.1.2 Compaq Insight Manager

Compaq Insight Manager is a Web-based system management utility. It consists of two different components: the Management Agents, which run on many different operating systems (including Tru64 UNIX), and the Management Console, which runs exclusively on Microsoft Windows NT.

By enabling the Compaq Management Agents on your Tru64 UNIX systems, you can provide a conduit for communication between these systems and the Web. Once enabled, this conduit allows you to access information about the configuration of your systems and their peripherals from a web browser on any system. In some Java-enabled web browsers, you can also invoke the SysMan Menu through this interface to manage these systems.

Figure 1-4 shows an example of using the Management Agents to obtain statistics for an Ethernet network adapter.

Figure 1–4: Compaq Management Agents

Using the Compaq Insight Manager XE Management Console, you can view and manage your systems as well as many standalone devices (such as printers, routers, and more) on your network. The Management Console is especially useful for managing heterogeneous environments, as it can communicate with the Management Agents for all of the supported operating systems and environments.

For more information about Compaq Insight Manager, see `insight_manager(5)` and the *System Administration* guide.

1.1.3 Other Interfaces

The operating system includes alternative system administration applications, some that require graphics capabilities and others that allow you to configure your system from the command line. This book mentions these optional utilities, when available, in relation to specific configuration tasks.

See Chapter 2 of the *System Administration* guide for a comprehensive list of the utilities that are available. See the reference pages and online help for more information about each utility.

1.1.4 Manually Editing Configuration Files

Some sections of this book describe the system files that are updated or modified when you perform an administrative task. Experienced UNIX administrators might prefer to administer their systems by manually editing these files, as opposed to invoking the documented utility; however, it is strongly recommended that you use the appropriate utilities to update the system files so that the structure of these files is preserved.

Important considerations are:

- **Context-Dependent Symbolic Links (CDSLs)**
Many system files now exist as special symbolic links (CDSLs) created to facilitate TruCluster Server clusters. The links are transparent to most users, but if the links are broken, the system cannot join a cluster in the future without recreating them. This manual mentions a few of the CDSLs, especially when you must create them manually. See the `hier(5)` reference page for a complete list of the CDSLs in the file system. See the *System Administration* guide for more information.
- **Binary databases, configuration definitions**
Many system components write data to both text and binary files, and their administrative utilities often recreate the binary files. Other system information is often preserved so that when you update your system, it can be recovered and reused, saving you time and effort.
- **Latent support for clusters**
Individual systems are capable of joining TruCluster Server clusters, and many system files have been modified to provide latent support for clusters. For example, the `rc.config` file now has two related files, `rc.config.common` and `rc.config.site`, which can store run-time configuration variables. Altering these files with the `rcmgr` utility ensures the integrity and consistency of these files.
- **Update installation**
During the update installation process, changed information is merged into existing system files. The `.new.*` and `.proto.*` files might be important in this process. Refer to the *Installation Guide* for more information.

In many cases, the SysMan Menu utility is the best alternative to manually editing system files, thus it is the utility that is most frequently covered in this manual.

1.1.5 Installation and Configuration Cloning

The operating system includes two features, Installation Cloning and Configuration Cloning, that allow you to minimize the amount of manual

intervention that is necessary to install and configure systems. These features are particularly useful if you need to set up many identical systems in the same way, because they allow you to capture the configuration of a working system in configuration description files (CDFs) and use those files to install and configure subsequent systems.

See the *Installation Guide — Advanced Topics* guide for more information.

2

Basic Network Connections

This chapter describes the basic Tru64 UNIX network environment, including how to configure:

- Ethernet
- Token Ring
- Fiber Distributed Data Interfaces (FDDI)
- Automatic network adapter failover (NetRAIN)
- Various network daemons in order to operate in a TCP/IP network environment

Note

This chapter discusses the configuration of network interfaces in an IPv4 environment. All references to IP and TCP/IP are IPv4-specific. For information about configuring IPv6 in a network environment, see Chapter 3.

In addition, this chapter describes some of the commands you can use to monitor the network environment.

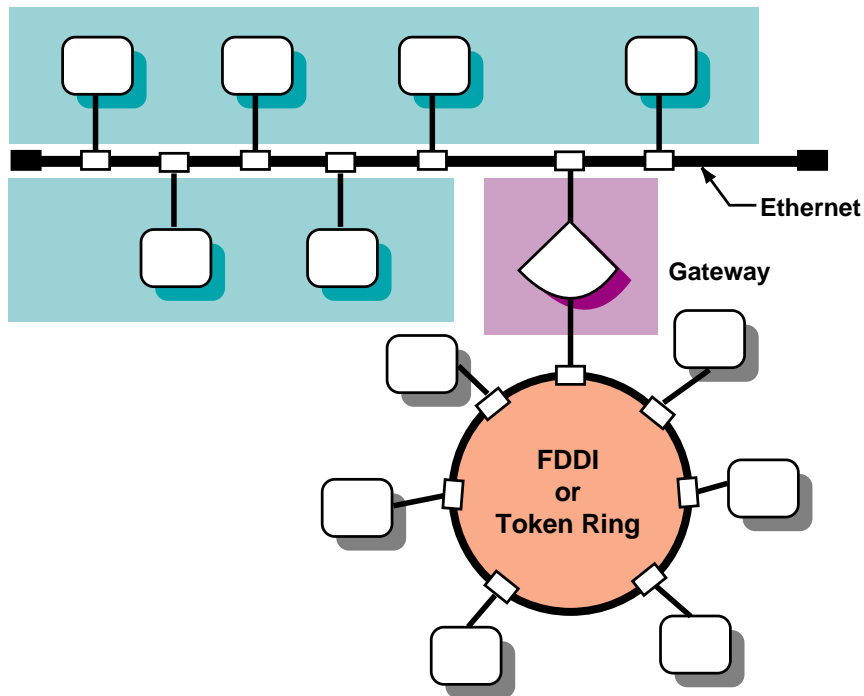

For information about ATM and point-to-point connections, see Chapter 4 and Chapter 6, respectively.

For troubleshooting information, see Section 15.3.

2.1 Network Environment

Figure 2-1 shows a sample corporate network in which there is an Ethernet backbone and an FDDI or Token Ring network connected to it through a gateway.

Figure 2–1: Sample Network Configuration

ZK-1147U-AI

2.2 Preparing for the Configuration

You configure the network components by using the Network Configuration application. The following sections contain worksheets that you can use to record the information required to configure the network components.

2.2.1 Information for Interfaces and Daemons

Figure 2–2 shows the Interface and Daemon Worksheet. The following sections explain the information you need to record on this worksheet. If you are viewing this manual online, you can use the print feature to print a copy of the worksheet.

Figure 2–2: Interface and Daemon Worksheet

Interface and Daemon Worksheet

All Network Interfaces
Adapter name: _____
Host name: _____
Internet address source: DHCP server User supplied
Internet address: _____
Network mask: _____

Token Ring interface
Adapter speed: _____

NetRAIN interface
Set members: _____

rwhod Daemon
rwhod: Yes No
Flags: Broadcast only Listen only Both

routed Daemon
routed: Yes No
Flags: Run routed on gateway host
 Write all packets to standard output
 Log additional information
RIP data: Supply Run quietly

Gateways File
Destination type: Net Host
Destination: _____
Gateway: _____
Hop count: _____
Route type: External Passive Active

gated Daemon
gated: Yes No
Configuration file: _____

IP Router
IP router: Yes No

2.2.1.1 All Network Interfaces

Adapter name

The device names of the network interfaces. The following table contains a list of selected network interfaces that the operating system supports:

Interface	Device Name
Ethernet	le
	ln
	tu
	xna
Fiber Distributed Data Interface (FDDI)	faa
	fta
	fza
Gigabit Ethernet	alt
Token Ring	tra

Note that if you configuring a NetRAIN interface, as documented in Section 2.4, the adapter name is the virtual device name of your NetRAIN set (nr).

Host name

The fully qualified host name assigned to your system. A fully qualified host name contains the host name and the domain name, with host name and each level of the domain name separated by a period (.). Ask the network administrator for a unique host name.

Internet address source

The source of your system's network address for Ethernet, FDDI, and NetRAIN interfaces only. If your network uses a Dynamic Host Configuration Protocol (DHCP) server to assign IP addresses to systems at boot time, check the DHCP server box. If you plan to assign an IP address and network mask as part of system configuration, check the User supplied box.

Internet address

The Internet Protocol (IP) address of your system. If you are going to supply your own IP address, write it in this space. If you will be using DHCP to assign IP addresses on a temporary basis, leave this space blank.

If you do not have a designated IP address for your network, you need to obtain one from one of the following services. Then, after you receive your network's address, assign a unique IP address and host name to each system on your network.

To obtain an Internet address for your network, contact:

American Registry for Internet Numbers
 4506 Daly Drive, Suite 200
 Chantilly, VA 20151

Voice: (703) 227-0660
FAX: (703) 227-0676
Email: reg-services@arin.net (for general information)
hostmaster@arin.net (for IP address registrations)
WWW: <http://www.arin.net>

In Europe, you can contact:

RIPE Network Coordination Center
Singel 258
1016 AB Amsterdam
The Netherlands

Voice: +31 20 535 4444
FAX: +31 20 535 4445

E-mail: ncc@ripe.net (for general information)
hostmaster@ripe.net (for IP address registrations)
WWW: <http://www.ripe.net>

In Asia and the Pacific region, you can contact:

Asia Pacific Network Information Center
Level 1, 33 Park Road
P.O. Box 2131
Milton, QLD 4064
Australia

Voice: +61 7 3367 0490
FAX: +61 7 3367 0482

E-mail: info@apnic.net (for general information)
hostmaster@apnic.net (for IP address registrations)
WWW: <http://www.apnic.net>

Note

It is a good idea to register your network even if you do not intend to connect to the Internet network. Then, if you decide to connect to the Internet network later, you will not have to change all the host addresses on your network.

Network mask

Your network's subnet mask. Subnetworks allow the systems on a local area network (LAN) to be known by one address to the Internet network, while being known locally by a set of addresses. Subnetworks can represent logical groupings of hosts, or different physical networks. If your network uses subnet network routing, each system on the network must have the same subnet mask defined. Use the following table to help identify your subnet mask. If you are not using subnetworks,

the *n* is zero (0); otherwise, the *n* is greater than zero and less than or equal to 255.

Class	IP Address Range	Subnet Mask
A	0.0.0.0 to 127.0.0.0	255. <i>n.n.n</i>
B	128.0.0.0 to 191.0.0.0	255.255. <i>n.n</i>
C	192.0.0.0 to 223.0.0.0	255.255.255. <i>n</i>

If you are connecting your system to an existing network that is using subnetwork routing, ask the network administrator for the correct subnet mask.

2.2.1.2 Token Ring Interface

Adapter speed

If your system supports token ring, the speed of your system's token ring adapter. Two speeds are supported: 4Mb/s and 16Mb/s. The default speed is 16Mb/s.

2.2.1.3 NetRAIN Interface

NetRAIN interfaces provide higher availability on systems that contain multiple network adapters. See Section 2.4 for more information.

Set members

The device names of the network interfaces that are part of the NetRAIN set. When one interface in the set ceases to function, NetRAIN will fail over to another interface on this list.

2.2.1.4 rwhod Daemon

The `rwhod` daemon maintains the database that is used by the `rwho` and `ruptime` programs. These programs provide basic information about the system and its current users to users on remote systems.

rwhod

If you want to run the `rwhod` daemon, check Yes; otherwise, check No.

Running the `rwhod` daemon allows you to use the `rwho` and `ruptime` commands.

Flags

If the `rwhod` daemon is to send `rwho` packets and ignore incoming packets, check Broadcast Only. If the daemon is to collect incoming

packets, but not broadcast `rwho` packets, check Listen Only. If the daemon is to do both, check Both.

See `rwhod(8)` for additional information.

2.2.1.5 routed Daemon

The `routed` daemon allows your system's internal routing tables for the Routing Information Protocol (RIP) to be updated automatically.

routed

If you want to run the `routed` daemon, check Yes; otherwise, check No. Use the `routed` daemon to manage your routes dynamically only if your network and system requirements match the criteria in the following table:

Criterion	Type or Value
Size of network	Medium to large Local Area Network or Wide Area Network, with multiple subnets
Network Topology	Variable
Number of routes required	Loopback, network interface route, and many others
Routers advertising routes	Yes
Configuration complexity	Low
System overhead	Low

You can choose to run the `routed` daemon or `gated` daemon, but not both. For more information about these daemons and static routing, see the *Best Practice for Network Routing* at the following URL:

http://www.tru64unix.compaq.com/faqs/publications/best_practices

Flags

Specifies how you want the `routed` daemon to run. You can run the `routed` daemon on a gateway host, write all packets to standard output, or log debugging information. Check the options you want. See `routed(8)` for more information.

RIP data

If the `routed` daemon is to supply RIP information, check Supply; otherwise, check Run Quietly.

2.2.1.6 Gateways File

The `gateways` file contains Internet routing information for the `routed` daemon. Specify the following parameters for the file:

Destination Type

If the route is to a network, check `Net`. If the route is to a specific host, check `Host`.

Destination

The destination name or IP address (in dotted-decimal format).

Gateway

The name or IP address of the gateway host to which messages will be forwarded.

Hop count

The hop count, or number of gateways, from the local network to the destination network.

Route type

If the gateway is expected to exchange RIP routing information, check `Active`. If the gateway is not expected to exchange routing information, check `Passive`. If the gateway is to notify `routed` that another routing process will install the route (it is not advertised through RIP), check `External`.

See `gateways(4)` for additional information.

2.2.1.7 gated Daemon

The `gated` daemon allows your system's internal routing tables for various routing protocols to be updated automatically.

gated

If you want to run the `gated` daemon, check `Yes`; otherwise, check `No`. Use the `gated` daemon to manage your routes dynamically only if your network and system requirements match the criteria in the following table:

Criterion	Type or Value
Size of network	Medium to large, with multiple subnets
Network Topology	Variable

Criterion	Type or Value
Number of routes required	Loopback, network interface route, and many others
Routers advertising routes	Yes
Configuration complexity	Moderate to high
System overhead	Low
System role	Host, router, or cluster member

You can choose to run the `gated` daemon or `routed` daemon, but not both. For more information about these daemons and static routing, see the *Best Practice for Network Routing* at the following URL:

http://www.tru64unix.compaq.com/faqs/publications/best_practices

Configuration file

The name of an alternate configuration file. By default, the `gated` daemon uses the `/etc/gated.conf` file.

2.2.1.8 IP Router

An IP router is a gateway host connected to more than one TCP/IP network that receives and forwards packets between the networks.

You can configure your system as an IP router if you have more than one network interface installed and configured. In addition, you must have configured either the `routed` or the `gated` daemon.

IP router

If you want the system to run as an IP router, check Yes; otherwise, check No.

2.2.2 Information for Network Files

Figure 2-3 shows the Network Files Worksheet. The following sections explain the information you need to record on this worksheet. If you are viewing this manual online, you can use the print feature to print a copy of the worksheet.

Figure 2–3: Network Files Worksheet

Network Files Worksheet		
Static Routes File (/etc/routes)		
Destination type:	Default gateway <input type="checkbox"/>	Host <input type="checkbox"/> Network <input type="checkbox"/>
Destination:	_____	
Route via:	Gateway <input type="checkbox"/>	Interface <input type="checkbox"/>
Gateway:	_____	
Hosts File (/etc/hosts)		
Host name:	_____	_____
Internet address:	_____	_____
Alias:	_____	_____
Hosts Equivalencies File (/etc/hosts.equiv)		
Host name:	_____	_____
User name:	_____	_____
Networks File (/etc/networks)		
Network name:	_____	_____
Network address:	_____	_____
Alias:	_____	_____

2.2.2.1 Static Routes File (/etc/routes)

The `routes` file specifies static routes that will be added to your system's internal routing tables when the system boots.

Use static routes only if your network and system requirements match the criteria in the following table:

Criterion	Type or Value
Size of network	Small LAN (hosts and one gateway/router)
Network Topology	Stable
Number of routes required	Loopback, network interface route, and a few others
Routers advertising routes	No
Configuration complexity	Low
System overhead	None

For more information about static routing, as well as the `gated` and `routed` daemons, see the *Best Practice for Network Routing* at the following URL:

http://www.tru64unix.compaq.com/faqs/publications/best_practices

If you choose to use static routes, specify the following parameters for the `routes` file:

Destination type

The specific path, as stored in the `/etc/routes` file, from your system to another host or network. A static route is not updated by network software. If you want to route to a default gateway, check Default Gateway; to a host, check Host; or to a network, check Network.

Destination

The name or IP address of the route destination. For default gateway, the default destination is `default`.

Route via

If you are routing through a gateway, check Gateway. If you are routing through an interface, check Interface.

Gateway

The name or IP address of the gateway or interface.

See `routes(4)` for additional information.

2.2.2.2 Hosts File (/etc/hosts)

The `hosts` file contains critical address information for the known hosts on the network. Specify the following parameters for the file:

Host name

The names of other hosts on the network to be added to the `/etc/hosts` file.

If your network is running a distributed database lookup service (DNS/BIND or NIS), you do not need to list each host on your network in your `/etc/hosts` file. However, it is a good idea to list four or five systems on the network designated as DNS/BIND or NIS servers in your `/etc/hosts` file.

Internet address

The IP addresses of other hosts on the network to be added to the `/etc/hosts` file.

Alias

The aliases, if any, of other hosts on the network to be added to the `/etc/hosts` file.

See `hosts(4)` for additional information.

2.2.2.3 Hosts Equivalencies File (/etc/hosts.equiv)

The `hosts.equiv` file contains the names of remote systems and users that can execute commands on the local system. Specify the following parameters for the file:

Host name

The name of the trusted hosts to be put in the `/etc/hosts.equiv` file. Systems listed in the `/etc/hosts.equiv` file are logically equivalent to, and therefore treated exactly the same as, the local system.

Setting up an `/etc/hosts.equiv` file is optional but, if you choose to have one on your system, you need to create it and add the names of any trusted hosts.

User name

The name of a user on a trusted host.

See `hosts.equiv(4)` for additional information.

2.2.2.4 Networks File (/etc/networks)

The `networks` file contains information about the known networks that your system needs to access. Specify the following parameters for the file:

Network name

The official Internet name of the network.

Network address

The IP address of the network.

Alias

The unofficial names used for the network to be added to the `/etc/networks` file.

See `networks(4)` for additional information.

2.3 Configuring the Network Components

Use the SysMan Menu application of the Common Desktop Environment (CDE) Application Manager to configure the following network components on your system:

- Network interfaces (Ethernet, FDDI, and Token Ring)
- Remote who service (`rwhod` daemon)

- Routing services (`routed daemon`, `gated daemon`, IP router)
- Static routes file (`/etc/routes`)
- Hosts file (`/etc/hosts`)
- Host equivalent file (`/etc/hosts.equiv`)
- Networks file (`/etc/networks`)

To invoke the SysMan Menu application, follow the instructions in Section 1.1.1. See the same section for information about time-saving alternatives for configuration tasks.

2.3.1 Configuring Network Interfaces

Use the following procedure to configure Ethernet, FDDI, or Token Ring network interfaces. For information about how to configure NetRAIN, see Section 2.4.

Note

If you are configuring a system that is new to this environment, verify that the network adapter mode is set correctly at the console level before continuing. For example, if you have a 10base2 Ethernet network and your system is configured to use 10baseT Ethernet, your system fails to see the network until you set the appropriate console variable. See the prerequisite tasks for a full installation in the *Installation Guide* for more information.

1. From the SysMan Menu, select Networking→Basic Network Services→Set up Network Interface Card(s) to display the Network Interface Card (NIC) dialog box.
Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman interface
```

All network adapters that are installed on the system are listed in the dialog box.
2. Select the network adapter that you would like to configure. The dialog box for the selected interface is displayed.
3. Enter the name for the interface in the Host Name field.
4. To configure an Ethernet interface, do the following:
 - a. To obtain the IP address data from the DHCP server, select the Use DHCP radio button. Otherwise, select the User Supplied Value radio button and enter the IP address and network mask data in the appropriate fields.

- b. Select the Additional Flags button to display the Additional Flags dialog box, which shows advanced configuration parameters for the selected interface.
 - c. Select the check boxes and radio buttons for the other interface options that you want to enable and enter values where necessary for optional `ifconfig` arguments.
 - d. Go to step 7.
 5. To configure an FDDI interface, do the following:
 - a. If you are to obtain the IP address data from the DHCP server, select the Use DHCP radio button. Otherwise, select the User Supplied Value radio button and enter the IP address and network mask data in the appropriate fields.
 - b. Select the Additional Flags button to display the Additional Flags dialog box, which shows advanced configuration parameters for the selected interface.
 - c. Select the check boxes and radio buttons for the interface options that you want to enable and enter values where necessary for optional `ifconfig` arguments.
 - d. Go to step 7.
 6. To configure a Token Ring interface, do the following:
 - a. Enter the IP address for the host device in the IP Address field.
 - b. Enter the mask variable for the interface in the Network Mask field.
 - c. Select the Additional Flags button to display the Additional Flags dialog box, which shows advanced configuration parameters for the selected interface.
 - d. Select the check boxes and radio buttons for the interface options that you want to enable and enter values where necessary for optional `ifconfig` arguments. Select the appropriate adapter speed: 4 or 16.
 - e. Go to step 7.
 7. Select OK to validate the parameters you entered and to close the Additional Flags dialog box. The dialog box for the adapter you are configuring is displayed.
 8. Select OK to validate the configuration for network interface and close the dialog box for the adapter. The NIC dialog box is displayed.

9. Repeat steps 2 through 8, if necessary, to configure additional adapters; otherwise, select OK start network services and apply your changes now. The system applies the changes and closes the NIC dialog box.

You can also use the NIC dialog box to modify and deconfigure network interfaces. See the online help for more information.

Note

Once a system is configured to use the network for the first time, CDE becomes network-dependent, and it might function inconsistently if network services become unavailable. Therefore, if you modify or deconfigure the network interface on a system with only one interface, your system might be left in a unpredictable state. For this reason, it is best to reboot immediately after modifying the network interface to prevent problems. Furthermore, if you deconfigure the network interface, you must configure a new network interface to replace it before rebooting.

2.3.2 Configuring the rwhod Daemon

To configure the `rwhod` daemon, do the following:

1. From the SysMan Menu, select Networking→Basic Network Services→Set up remote who services (`rwhod`) to display the Remote Who dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman rwhod
```

The utility asks if you want to run the remote who service on your system.

2. Select the Yes radio button to enable the remote who service.
3. Select the appropriate `rwhod` flag radio button.
4. Select OK to save the changes. The utility notifies you that the changes are saved and asks if you want to apply the changes now.
5. Select Yes to apply your changes now, or select No to close the Routing Services dialog box and apply the changes the next time you reboot your system.
6. Select OK to dismiss the informational message and to close the Remote Who dialog box.

You can also use the Remote Who dialog box to disable the `rwhod` daemon. See the online help for more information.

2.3.3 Configuring the routed Daemon

To configure the `routed` daemon, do the following:

1. From the SysMan Menu, select Networking→Basic Network Services→Set up routing services (gated, routed, IP Router) to display the Routing Services dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman routing
```

The utility displays a list of options you can use to configure the `gated` and `routed` daemons and to set up your system as an IP router.

2. Select Yes (use `routed`) radio button to enable the `routed` daemon.
3. Select the appropriate checkbox if you want to run your system as an IP router.
4. Select the appropriate check box if you want to run the `routed` daemon on a gateway.
5. Select the Supply RIP Data radio button if you want the `routed` daemon to run on a gateway host and supply Routing Information Protocol (RIP) data. Select the Run Quietly radio button if you do not want the `routed` daemon to supply RIP information.
6. Select the Configure Gateways button to display the Gateways dialog box. Do the following:
 - a. Select Add to add a new gateway. The Add/Modify dialog box is displayed.
 - b. In the Destination Type field, select the Network radio button if the destination is a network. Select the Specific Host radio button if the destination is a host.
 - c. Enter the destination name, IP address, or “default” in the Destination field.
 - d. Enter the name or IP address of the gateway host in the Gateways field.
 - e. Enter the hop count in the Hop Count field.
 - f. Select one of the Gateway Type radio buttons.
 - g. Select OK to validate the information you entered and close the Add/Modify dialog box. Repeat steps a through g for additional gateways.
 - h. Select OK to save the changes and close the Gateways dialog box.

7. Select OK in the Routing Services dialog box to save the changes. The utility displays a dialog box to confirm the changes and to ask if you want to start the daemon now.
8. Select Yes to start the daemon and apply your changes now, or select No to close the Routing Services dialog box and apply the changes the next time you reboot your system.

If you choose Yes, you are informed that the daemon is running. Select OK to dismiss the message and to close the Routing Services dialog box.

You can also use the Routing Services dialog box to disable the `routed` daemon. See the online help for more information.

See the `routed(8)` and `gateways(4)` reference pages for more information about the `routed` daemon and the `gateways` file.

2.3.4 Configuring the `gated` Daemon

To configure the `gated` daemon, do the following:

1. From the SysMan Menu, select Networking→Basic Network Services→Set up routing services (`gated`, `routed`, IP Router) to display the Routing Services dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman routing
```

The utility displays a list of options you can use to configure the `gated` and `routed` daemons and to set up your system as an IP router.

2. Select the Yes (use `gated`) radio button to enable the `gated` daemon.
3. Select the appropriate check box if you want to run your system as an IP router.
4. Enter the file name of the `gated` configuration file in the Configuration File field.

Note

To configure the `gated` daemon, you must set up the `/etc/gated.conf` file in the format specified in `gated.conf(4)`. A default `/etc/gated.conf` file is provided when you install the software.

5. Select OK in the Routing Services dialog box to save the changes. A dialog box is displayed to confirm the changes and to ask if you want to start the daemon now.

6. Select **Yes** to start the daemon and apply your changes now, or select **No** to close the Routing Services dialog box and apply the changes the next time you reboot your system.

If you choose **Yes**, you are informed that the daemon is running. Select **OK** to dismiss the message and to close the Routing Services dialog box.

You can also use the Routing Services dialog box to disable the `gated` daemon. See the online help for more information.

See the `gated(8)` and `gated.conf(4)` reference pages for more information about the `gated` daemon and the `gated.conf` file.

2.3.5 Configuring the System as an IP Router

In order to function as an IP router, your system must have two network interfaces installed and configured and must have the `routed` or `gated` daemon configured. To configure the system as an IP router, do the following:

1. From the SysMan Menu, select **Networking**→**Basic Network Services**→**Set up routing services (gated, routed, IP Router)** to display the Routing Services dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman routing
```

The utility displays a list of options you can use to configure the `gated` and `routed` daemons and to set up your system as an IP router.

2. Select the appropriate check box to run your system as an IP router.
3. Select **OK** to save the changes. A dialog box is displayed to confirm the changes and to ask if you want to start or restart the `routed` or `gated` daemon.
4. Select **Yes** to start the daemon and apply your changes now, or select **No** to close the Routing Services dialog box and apply the changes the next time you reboot your system.

If you choose **Yes**, you are informed that the daemon is running. Select **OK** to dismiss the message and to close the Routing Services dialog box.

You can also use the Routing Services dialog box to deconfigure the system as an IP router. See the online help for more information.

2.3.6 Configuring the Static Routes File

To configure the `routes` file, you add entries (static routes) to the `routes` file. Do the following:

1. From the SysMan Menu, select **Networking→Basic Network Services→Set up static routes (/etc/routes)** to display the Static Routes dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman route
```

2. Select **Add** to add a static route. The Add/Modify dialog box is displayed.
3. Select one of the Destination Type radio buttons.
4. For host and net destinations:
 - a. Enter the full name or IP address of the destination network or host in the Destination field.
 - b. Select one of the Route Via radio buttons. Select the Gateway button if the route is through a gateway. Select the Interface button and skip to step 6 if the route is through an interface.
5. For a gateway, enter the full name or IP address of the gateway host to which messages will be forwarded in the Gateway field.
6. Select **OK** to validate the entry and add it to the list. Repeat steps 2 through 6 for additional static routes.
7. Select **OK** to save the current changes. A dialog box is displayed to confirm the changes and to ask if you want to start the static routes service.
8. Select **Yes** to start the service and apply your changes now. Or, select **No** to close the Static Routes dialog box and apply the changes the next time you reboot your system.

If you choose **Yes**, select **OK** to close the Static Routes dialog box.

You can also use the Static Routes dialog box to modify and delete entries in the `routes` file. See the online help for more information.

See the `routes(4)` reference page for more information about the `routes` file.

2.3.7 Configuring the hosts File

To configure the `hosts` file, do the following:

1. From the SysMan Menu, select **Networking→Basic Network Services→Set up hosts file (/etc/hosts)** to display the Hosts dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman host
```

2. Select Add to add a host. The Add/Modify dialog box is displayed.
3. Enter an official host name in the Host Name field.
4. Enter the IP address of the new host in the Host Address field.
5. Optionally, enter any unofficial name or names for this host in the Aliases field. Also, provide pertinent information, for example, the location of the host, in the Comment field.
6. Select OK to validate the entry and add it to the list. Repeat steps 2 through 6 for additional hosts.
7. Select OK to update the `/etc/hosts` file and to close the Hosts dialog box.

You can also use the Hosts dialog box to modify and delete entries in the `hosts` file. See the online help for more information.

See the `hosts(4)` reference page for more information about the `hosts` file.

2.3.8 Configuring the `hosts.equiv` File

To configure the `hosts.equiv` file, do the following:

1. From the SysMan Menu, select Networking→Basic Network Services→Set up host equivalency file (`/etc/hosts.equiv`) to display the Hosts Equivalency dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman hosteq
```

2. Select Add to add a host. The Add/Modify dialog box is displayed.
3. Enter the remote host name in the Host field.

Note

If the host is not on the network, you cannot add the host.

4. Enter the name of a user on the remote host in the User field.
5. Select OK to validate the entry and add it to the list. Repeat steps 2 through 5 for additional remote hosts.
6. Select OK to update the `/etc/hosts.equiv` file and to close the Hosts Equivalency dialog box.

The Hosts Equivalency dialog box also enables you to modify and delete entries in the `hosts.equiv` file. See the online help for additional information.

See the `hosts.equiv(4)` reference page for more information about the `hosts.equiv` file.

2.3.9 Configuring the networks File

To configure the `networks` file, do the following:

1. From the SysMan Menu, select Networking→Basic Network Services→Set up the networks file (/etc/networks) to display the Networks dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman networks
```

2. Select Add to add a network. The Add/Modify dialog box is displayed.
3. Enter the official network name in the Network Name field.
4. Enter the IP address of the network in the Network Address field.
5. If an unofficial name (alias) is assigned to the new network, enter the aliases in the Aliases field.
6. Select OK to validate the entry and add it to the list. Repeat steps 2 through 6 for additional networks.
7. Select OK to update the `/etc/networks` file and to close the Networks dialog box.

You can also use the Networks dialog box to modify and delete entries in the `networks` file. See the online help for more information.

See the `networks(4)` reference page for more information about the `networks` file.

2.3.10 Configuring IP Aliases

An IP alias is an additional network address for an interface. The alias is usually an address in the same subnet as the primary IP address on the interface.

To configure an IP alias, you need the following information:

- IP alias address
- Netmask value associated with the IP alias address
- Host name associated with the IP alias address

To configure an IP alias, do the following:

1. Add the IP address and host name to the `/etc/hosts` file (see Section 2.3.7).
2. Edit the `/etc/inet.local` file and add the command to configure the alias. Use the following syntax:

```
ifconfig interface alias IP_alias_address netmask IP_alias_netmask
```

For example:

```
ifconfig tu0 alias 18.54.76.129 netmask 255.255.255.0
```

See the `ifconfig(8)` reference page for more information on `ifconfig` parameters.

3. Restart network services by entering the following command:

```
# rcinet restart
```

2.4 NetRAIN Interfaces

The Redundant Array of Network Adaptors (NetRAIN) interface provides a mechanism to protect against certain kinds of network connectivity failures.

NetRAIN integrates multiple network interfaces on the same LAN segment into a single virtual interface called a NetRAIN set. One network interface in the set is always active while the others remain idle. If the active interface fails, one of the idle set members comes online with the same IP address within an adjustable failover time period.

NetRAIN monitors the status of its network interfaces with the Network Interface Failure Finder (NIFF), a tool used to detect and report possible network failures. These tools can be used independently of NetRAIN. For more information about NIFF, see the `niff(7)` reference page.

2.4.1 Configuring NetRAIN

The following sections describe how to configure the hardware and the network interfaces for a NetRAIN set.

2.4.1.1 Hardware Restrictions, Configuration, and Licensing

Before you set up the NetRAIN virtual interface, note the following hardware restrictions and configuration tips:

- You must construct a NetRAIN set out of interfaces that are currently idle. This means the interfaces cannot be marked as "up" in the Set up Network Interface Card(s) dialog box of the SysMan Menu and they cannot have IP addresses assigned to them.

- You must use two or more of the same type of network interface (FDDI, ATM LAN Emulation, or Ethernet) dedicated to a single LAN segment. If you use Ethernet adaptors, they must all be of the same speed.
- You cannot run LAT over a NetRAIN virtual interface (`nr`) or any of the interfaces that compose a NetRAIN set.
- It is best to run separate cables from each network adapter to the appropriate hub or concentrator to provide physically redundant paths back to the network. This reduces the chance of network failure due to cables being accidentally unplugged.
- If necessary, you can adjust the timeout values to ensure that NetRAIN will successfully detect and respond to network failure. You can tune these parameters with the `sysconfig` command, `ifconfig` command, and the `ioctl` system call. See the `nr(7)`, `ifconfig(8)`, `sysconfig(8)`, `dxkerneltuner(8)`, and `sys_attrs_netrain(5)` reference pages for details.

By default, these parameters are tuned for operation over Ethernet, but it is possible that the default values and other suggested timeout values will not work in your environment. For example, if you are connected to a switch, failover time will depend on the switch and its configuration.

- You must use UNI Version 3.1 when running NetRAIN over LANE to obtain acceptable failover times with some ATM switches, including the Gigaswitch. If you use UNI Version 3.0, the failover time might be long because the T309 timer is set to 90 seconds by default on some switches. If the T309 timer is adjustable on your switch, you can set the T309 timer to 10 seconds as in UNI Version 3.1 to try to achieve acceptable failover times.

NetRAIN and MAC Address Licensing Schemes

Licensing schemes that use a network adapter's Media Access Control (MAC) address to uniquely identify a machine can be affected by how NetRAIN changes the MAC address.

All network drivers support the `SIOCRPHYSADDR` `ioctl` that fetches MAC addresses from the interface. This `ioctl` returns two addresses in an array:

- Default hardware address
The permanent address that is taken from the small PROM that each LAN adapter contains.
- Current physical address
The address that the network responds to on the wire.

Licensing schemes based on MAC addresses must use the default hardware address returned by the `SIOCRPHYSADDR` `ioctl`; do not use the current

physical address because NetRAIN modifies this address for its own use. See the reference page for your network adapter (for example `ln(7)` and `tu(7)`) for a sample program that uses the `SIOCRPHYSADDR` ioctl.

2.4.1.2 Configuring the NetRAIN Interface

NetRAIN configuration parameters are stored in the `/etc/rc.config` file along with the parameters for other network interfaces. Use the `rcmgr` utility to change the values of the variables. For more information about the `rcmgr` utility, see the `rcmgr(8)` reference page.

Note

The NetRAIN parameters in the following steps are case sensitive and must be typed in uppercase as shown.

To configure NetRAIN, do the following:

1. Log in as root.
2. Construct the NetRAIN set or sets, as follows:
 - a. Set the NetRAIN interface name or names:

```
# rcmgr set NRDEV_n netrain-interface-id
```

The `netrain-interface-id` must have the form `nrn`.

Specify the same integer `n` for the `NRDEV_n` variable and the `nrn` interface. For example, if no NetRAIN interfaces are configured on your system, you can specify `NRDEV_0` and `nr0`, respectively.

- b. Indicate which network interfaces will be part of the NetRAIN set or sets and, if necessary, provide failover timeout values:

```
# rcmgr set NRCONFIG_n interface-id,interface-id [nrtimers integer,integer]
```

Note

When specifying the interfaces, do not leave any spaces between the `interface-id` parameters and the commas. For example, for two Ethernet interfaces, you can specify `tu0,tu1` but not `tu0, tu1`.

The `nrtimers` values dictate how long the system is to wait before switching between interfaces. For more information about `nrtimers` values, see Section 2.4.1.1 and the `ifconfig(8)` reference page.

- c. Indicate to the system that you have configured a NetRAIN set:

```
# rcmgr set NR_DEVICES integer
```

Increment *integer* by the number of NetRAIN sets you have created. For example, if you create one NetRAIN set, *integer* is 1.

3. Configure the network parameters for the NetRAIN set or sets that you created, as follows:

- a. Set the interface name:

```
# rcmgr set NETDEV_n netrain-interface-id
```

For *netrain-interface-id*, use the same *nrn* ID you specified in step 2a.

If you configured other network interfaces in the `rc.config` file, you need to find and use the next available `NETDEV_n` variable. For example, if you used `NETDEV_0` to configure an Ethernet card that is not part of the NetRAIN set, the next available variable is `NETDEV_1`.

- b. Set the `ifconfig` parameters that will be used to initialize the NetRAIN interface:

```
# rcmgr set IFCONFIG_n IP-address netmask network-mask
```

As in step 3a, if you configured other network interfaces in the `rc.config` file, you need to use the next available `IFCONFIG_n` variable.

- c. Indicate to the system that you have configured an additional network interface:

```
# rcmgr set NUM_NETCONFIG integer
```

Increment *integer* by the number of NetRAIN interfaces you have created. If you configured other network interfaces in the `rc.config` file, you need to add the number of NetRAIN interfaces to the current `NUM_NETCONFIG` value from that file.

4. Restart network services to apply the changes.

After you configure a NetRAIN set, the NetRAIN interface is available each time you restart your system.

Optionally, you can configure NetRAIN interfaces from the command line by using the `ifconfig` command, but the changes are not preserved when you reboot. For more information, see the `ifconfig(8)` reference page.

Example 2–1 and Example 2–2 show the commands you would enter to establish two different NetRAIN configurations.

To create one NetRAIN set with two Ethernet interfaces, `tu0` and `tu1`, on a system where no other network interfaces have been configured, you would enter the commands in Example 2–1.

Example 2–1: Creating One NetRAIN Set

```
# rcmgr set NRDEV_0 nr01
# rcmgr set NRCONFIG_0 tu0,tu12
# rcmgr set NR_DEVICES 13
# rcmgr set NETDEV_0 nr04
# rcmgr set IFCONFIG_0 18.240.32.40 netmask 255.255.255.05
# rcmgr set NUM_NETCONFIG 16
```

- ¹ Creates a NetRAIN set called `nr0`.
- ² Indicates that the `nr0` set consists of the `tu0` and `tu1` interfaces.
- ³ Indicates to the system that there is one NetRAIN set.
- ⁴ Creates a network interface called `nr0` for the NetRAIN virtual interface.
- ⁵ Defines the IP address and network mask for the NetRAIN virtual interface.
- ⁶ Indicates to the system that there is one network interface.

To create two NetRAIN sets, one with two FDDI interfaces called `fta0` and `fta1` and the other with two ATM LANE interfaces called `elan0` and `elan1`, on a system where one other network interface has been configured (suppose `NETDEV_0` is `tu0`), you would enter the commands in Example 2–2.

Example 2–2: Creating Two NetRAIN Sets

```
# rcmgr set NRDEV_0 nr01
# rcmgr set NRDEV_1 nr1
# rcmgr set NRCONFIG_0 fta0,fta12
# rcmgr set NRCONFIG_1 elan0,elan1 nrtimers 4,163
# rcmgr set NR_DEVICES 24
# rcmgr set NETDEV_1 nr15
# rcmgr set NETDEV_2 nr2
# rcmgr set IFCONFIG_1 18.240.31.40 netmask 255.255.255.06
# rcmgr set IFCONFIG_2 18.240.31.42 netmask 255.255.255.0
# rcmgr set NUM_NETCONFIG 37
```

- ¹ Creates two NetRAIN sets called `nr0` and `nr1`.
- ² Indicates that the `nr0` set consists of the `tu0` and `tu1` interfaces.
- ³ Indicates that the `nr1` set consists of the `elan0` and `elan1` interfaces. Also provides `nrtimers` failover values for the set. The values in this example are suggested starting values for ATM LANE. They might not work for your configuration, as described in Section 2.4.1.1. For more information about `nrtimers` values, see the `ifconfig(8)` reference page.
- ⁴ Indicates to the system that there are two NetRAIN sets.

- 5 Creates network interfaces called `nr0` and `nr1` for the two NetRAIN virtual interfaces.
- 6 Defines the IP address and network mask for each NetRAIN virtual interface.
- 7 Indicates to the system that there are three network interfaces, the two NetRAIN virtual interfaces and the preexisting Ethernet interface.

2.4.2 Monitoring NetRAIN Activity

To check which member of a NetRAIN set is the active interface, use the `ifconfig` command. For example:

```
#ifconfig nr0
nr0: flags=8c63      NetRAIN Attached Interfaces: ( fta0 fta1 ) Active Interface:
( fta0 )inet 18.240.32.40 netmask ffffffff broadcast 18.240.32.255 ipmtu 4352
```

This example shows that:

- The virtual interface `nr0` is running; its IP address is `18.240.32.40`.
- The NetRAIN set consists of two physical interfaces, `fta0` and `fta1`.
- NetRAIN is using `fta0` for communication. If NetRAIN determines that `fta0` is not active, it switches to the next interface in the set, `fta1`.

To see the status of all set members while the NetRAIN interface is running, use the `niffconfig` command. For example:

```
#niffconfig -u
Interface:  tu1, state: DEAD, t1: 4, dt: 2, t2: 10, time to dead: 0,
current_interval: 2, next time: 2
Interface:  nr0, state: GREEN, t1: 4, dt: 2, t2: 10, time to dead: 0,
current_interval: 4, next time: 4
Interface:  tu0, state: GREEN, t1: 4, dt: 2, t2: 10, time to dead: 0,
current_interval: 4, next time: 4
```

In this example, you can see that the virtual interface `nr0` is running and NetRAIN is using `tu0` for communication. This example also shows the `nrtimers` values for each member of the set. See the `ifconfig(8)` reference page for more information on these values.

2.5 Configuring Multiple Network Interfaces in the Same Subnet

You can configure multiple active network adapters in one system, even if they operate on the same subnetwork. For example, you can configure a `tu0` interface at `192.24.156.20` and a `tu1` interface at `192.24.156.21`, both with the same netmask.

When you establish a connection, the kernel routes the connection through the interface that has the fewest number of connections. This

connection-balancing effect can lead to greater throughput than on a system with just one network adapter per subnetwork.

This feature differs from NetRAIN because it does not give you increased reliability or failover, it simply gives a system multiple paths to access the network.

Network administrators might choose to configure a system with multiple interfaces in the same subnetwork for various reasons. For example:

- The current environment has only a single subnet, but additional bandwidth is needed to certain systems.
- The site cannot upgrade its network infrastructure to newer, faster technologies, such as Gigabit Ethernet, which would improve network throughput.
- The source of a bottleneck is a particular system's network connection, but the switch to which it is connected is under-utilized and has additional ports and bandwidth available. Another connection to this system would reduce resource contention.
- There are no additional IP subnetworks assigned or available for configuration, and the host requires more bandwidth to access the current subnetwork than one network interface card allows.

For the system to function properly when configured in this manner, it must meet all of these conditions:

- It must be part of one of the following physical network layouts:
 - Switched Ethernet (10/100/Gigabit)
 - Switched Fiber Distributed Data Interface (FDDI)
 - ATM Classical IP (CLIP)
 - ATM LAN Emulation (LANE)
 - Point-to-Point (PPP)
- It must not be running a routing daemon (either `gated` or `routed`).
- It must have access to all remote systems through each interface that is configured in the same subnet. For example, you must be able to successfully issue a `ping` command to the same remote system when each network interface is configured by itself. This implies that all interfaces in the system are connected to the same physical network switch.

This feature might affect the operation of network software or commands that rely on the network interface staying constant for the life of a connection. For example:

- Multicast transmission might not work properly.

- Utilities such as `traceroute` might give inconsistent output, since the interface used might change from packet to packet.

No special settings are required to use this feature. Configure the network interfaces as directed in Section 2.3.1 and assign the interfaces IP addresses in the same subnet.

By default, configuring an interface adds an additional interface route into the routing table. If you wish to add routes using the `route` command or the `/etc/routes` file, see the `route(8)` reference page for details on adding routes on multiple interfaces. For example, you might want to add a default route on multiple interfaces. See `netstat(1)` for information on how to view the kernel routing table.

2.6 Enabling Access Filtering on an Interface

Interface access filtering helps you detect and prevent IP spoofing attacks. To enable interface access filtering on an interface, do the following:

1. Create an `/etc/ifaccess.conf` file and add entries against which the source address of input packets are checked.
2. Use the `ifconfig` command with the `+filter` parameter to enable access filtering on the network interface.

See `ifaccess.conf(4)` and `ifconfig(8)` for more information.

2.7 Monitoring the Local Host's Status

You can use the `netstat` command to monitor the status of the local host by viewing the contents of network-related data structures. You can select several forms of display; each allows you to specify the type of information you want to emphasize.

Table 2-1 shows the `netstat` command options.

Table 2-1: Options to the `netstat` Command

Option	Function
<code>-A</code>	Displays the address of any associated protocol control blocks.
<code>-a</code>	Includes information for all sockets.
<code>-f address_family</code>	Includes statistics or address control block reports for the specified address family.
<code>-I interface</code>	Displays information about the specified interface.
<code>-i</code>	Provides status information for autoconfigured interfaces.

Table 2–1: Options to the netstat Command (cont.)

Option	Function
-m	Displays information about memory management usage.
-n	Lists network addresses in number form rather than symbolic form.
-r	Lists routing tables.
-s	Provides statistics per protocol.
-t	Displays the time until the interface watchdog routine starts (for use with the -i option).

The `-I` option provides statistics for a specific interface. See Appendix A for an example of using the `-I` option to monitor Ethernet, Fiber Distributed Data Interface (FDDI), and token ring interfaces, and a description of the counters, status, and characteristics.

The `-i` option provides statistics on each configured network interface. Outgoing packet errors (Oerrs) indicate a potential problem with the local host. Incoming errors (Ierrs) indicate a potential problem with the network connected to the interface.

See `netstat(1)` for more information on this command and its options.

The following example shows normal output (no Ierrs or Oerrs) from the `netstat` command with the `-i` option:

```
% netstat -i
Name Mtu Network Address Ipkts Ierrs Opkts Oerrs Coll
ln0 1500 <Link> 8324125 0 8347463 0 237706
ln0 1500 16.31.16 host1 8324125 0 8347463 0 237706
fza0* 4352 <Link> 0 0 0 0 0
sl0* 296 <Link> 0 0 0 0 0
sl1* 296 <Link> 0 0 0 0 0
tra0 4092 <Link> 34 0 20 0 0
tra0 4092 16.40.15 host21 34 0 20 0 0
lo0 1536 <Link> 909234 0 909234 0 0
lo0 1536 loop localhost 909234 0 909234 0 0
```

2.8 Displaying and Modifying the FDDI Parameters

You use the `fddi_config` command to display and modify the FDDI adapter parameters.

To display the FDDI adapter parameters, use the `fddi_config` command with the following syntax:

```
fddi_config -i interface_name -d
```

To modify the FDDI adapter parameters, log in as root and use the `fddi_config` command with one or more of the options in Table 2–2.

Table 2–2: Options to the fddi_config Command

Option	Function
-i <i>interface_name</i>	Changes or displays the FDDI characteristics for <i>interface_name</i> . You must provide the interface name.
-c <i>counter_update_interval</i>	Determines how often the driver counters are updated by the DEFTA adapter. The default is 1 second. Setting the interval time to zero (0) disables counter updates. (For the DEFTA (fta) FDDI interface only.)
-d	Displays the FDDI interface parameters you can set.
-l <i>lem_threshold</i>	Sets the error rate threshold of Link Error Monitor (LEM). The LEM error rate threshold is 1×10^{-n} , where <i>n</i> ranges from 5 to 8, inclusively. The default LEM threshold is 1×10^{-8} .
-p [1 0]	Sets the ring purger state for the specified FDDI interface. A value of 1 enables the ring purger ability; a value of 0 disables it.
-r <i>restricted_token_timeout</i>	Sets the Restricted Token Timeout parameter, defining how long a single restricted mode dialog can last before being terminated. The range for this parameter is from 0 to 10000 milliseconds. The default value is 1000 milliseconds.
-t <i>token_request_time</i>	Sets the Request Token Rotation Time (T_req) for <i>interface_name</i> . T_req is used during the ring initialization process to negotiate a Target Token Rotation Time (TTRT) for the ring. The range for this parameter is from 4.0 milliseconds to 167.77208 milliseconds. The default value is 8.0 milliseconds.
-v <i>valid_transmit_time</i>	Sets the Valid Transmission Time (TVX) timer for a specific FDDI interface. The range for the TVX timer is from 2.35 milliseconds to 5.2224 milliseconds. The default is 2.6214 milliseconds.
-x [1 0]	Enables (1) or disables (0) full-duplex operation for the interface. If the full-duplex operation is enabled, the interface is in one of the following states: Idle, Request, Confirm, or Operational. (For the DEFTA (fta) FDDI interface only.)

See `fddi_config(8)` for more information on this command and its options.

The following example shows how to display the FDDI interface parameters you can set:

```
% /usr/sbin/fddi_config -i fza0 -d
fza0 ANSI FDDI settable parameters

Token Request Time:          0.0000 ms
Valid Transmission Time:    0.0000 ms
LEM Threshold:              0
Restricted Token Timeout:    15.8314 ms
Ring Purger State:          (null)

fza0 Full Duplex Mode: Disabled

fza0 Counter Update Interval: 10 sec
```

The following example shows how to change the Token Request Time (TRT) value for the fza0 interface to 10.2:

```
# fddi_config -t10.2 -i fza0
```

The following example shows how to turn the ring purger off:

```
# fddi_config -p 0 -i mfa0
```

2.9 Managing Token Ring Source Routing

Source routing is a bridging mechanism that systems on a token ring LAN use to send messages to a system on another interconnected token ring LAN. Under this mechanism, the system that is the source of a message uses a route discovery process to determine the optimum route over token ring LANs and bridges to a destination system. The source system stores the optimum routes in its source routing table.

When the system is booted with the DETRA adapter installed and configured, token ring source routing is initialized by default. To manage token ring source routing, use the `srconfig` command.

Table 2-3 shows the `srconfig` command options. All `srconfig` command options are case insensitive; type them in uppercase, lowercase, or mixed case. The short form for each flag is indicated by uppercase letters.

Table 2-3: Options to the `srconfig` Command

Option	Function
-DElentry <i>mac_address</i> ^a	Deletes a source routing table entry.
-DISEntry <i>mac_address</i> ^a	Disables a source routing table entry. This marks the entry as Stale.
-RAttr	Displays the source routing attributes.

Table 2–3: Options to the srconfig Command (cont.)

Option	Function
-RCounter	Displays the source routing counters.
-REntry <i>mac_address</i>	Displays a specific source routing table entry.
-RTable	Displays the source routing table.
-SETAgetimer <i>timer</i> ^a	Sets the value of the Source Routing Aging Timer, specifying the length of time a source routing table entry remains valid until being marked as invalid or Stale. If not set, the system default is 120 seconds.
-SETDsctimer <i>timer</i> ^a	Sets the Source Routing Discovery Timer, specifying the amount of time a route discovery process can take before it terminates. If not set, the system default is 5 seconds.
-SETMaxentry <i>value</i> ^a	Sets the maximum number of entries allowed in the source routing table. The range for this entry is a multiple of 256 from 1024 to 2048. This parameter can be increased, but not decreased. If not set, the system default is 1024.
-u	Specifies that the MAC addresses are in uncanonical form. This option can be used with the <code>-DElEntry mac_address</code> , <code>-DISEntry mac_address</code> , and <code>-RTable</code> options only.
-Zcounter	Sets the source routing counters to zero.

^a Requires superuser privileges.

See `srconfig(8)` for more information on this command and its options.

The following example increases the number of routing table entries from 1024 to 1280 by using the shortened form of the `-SetMaxEntry` option:

```
# srconfig -setm 1280
Current SR Table size is : 1024
New SR Table size is : 1280
```

The following example displays the source routing attributes by using the shortened form of the `-RAAttr` option:

```
# srconfig -ra
Source Routing is enabled
Current SR Aging Timer      : 120
Current SR Discovery Timer  : 10
Current SR Table size is   : 1024
```

The following example displays the source routing counters by using the shortened form of the `-RCounter` option:

```
# srconfig -rc
ARE Frames Sent      : 00000001
ARE Frames received  : 00000000
Route Discovery Failures : 00000001
```

The following example displays all entries, with MAC addresses in canonical form, in the source routing table, by using the shortened form of the `-RTable` option. The backslash (`\`) character indicates line continuation and does not appear in the actual output.

```
# srconfig -rt
Target Node MAC Address 00-00-0C-01-08-E9 (ip = 130.180.4.3) \
Have Route 1
Routing Information: SRF, length 8, direction 0,largest frame \
4472 octets 2
Route Descriptors: 021C 7FFC 0220 0000 0000 0000 0000 0000 3

Target Node MAC Address 00-00-C9-10-1B-F5 On Ring 4

Target Node MAC Address 08-00-2B-2C-F1-F9 (ip = 130.180.4.2) \
Stale (Have Route) 5
Routing Information: SRF, length 8, direction 0,largest frame 4472 octets
Route Descriptors: 021C 7FFC 0220 0000 0000 0000 0000 0000

Target Node MAC Address 00-00-C9-0B-33-80 Stale (On Ring)
```

- 1 Have Route indicates the source system has a valid path to the destination system.
- 2 Information returned by the destination system in response to the route discovery process.
- 3 The LAN segments and bridges that constitute the path to the destination system.
- 4 On Ring indicates the destination system is on the same ring as the source system and does not need source routing.
- 5 Stale indicates the entry is invalid and needs to be updated by the route discovery process.

The following example shows all entries, with MAC addresses in noncanonical form, in the source routing table by using the shortened form of the `-RTable` option. The backslash (`\`) character indicates line continuation and does not appear in the actual output.

```
# srconfig -rt -u
Target Node MAC Address 00:00:30:80:10:97 (ip = 130.180.4.3) Have Route
Routing Information: SRF, length 8, direction 0,largest frame 4472 octets

```

2.10 Displaying and Modifying the Token Ring IP MTU Size

By default, the DETRA adapter uses an IP maximum transfer unit (MTU) size of 4092 bytes. In a multivendor environment with different adapters using different IP MTU sizes, the bridges connecting different networks can be set up to forward smaller packet sizes. As a result, bridges might drop packets or remote hosts might reject packets. If either occurs on your network, reduce the IP MTU size for all hosts on the network and ensure that all hosts use the same size.

The following command displays the DETRA interface IP MTU size as 4092 bytes:

```
% ifconfig tra0
tra0: flags=9863<UP,BROADCAST,NOTRAILERS,RUNNING>
      inet 16.141.208.3 netmask ffffffff broadcast 16.141.208.255 ipmtu 4092
```

The following example sets the IP MTU size of DETRA interface to 2044 bytes:

```
% ifconfig tra0 ipmtu 2044
```

2.11 Managing Network Quality of Service

As applications place increasing demands for bandwidth on the Internet network, increasing the network bandwidth is only a temporary solution. Newer real-time applications demand both increased bandwidth and low latency. Clearly, the importance of bandwidth management is increasing.

An IP network with its Best Effort delivery service performs a form of passive bandwidth management. If an outgoing queue is full, indicating high network traffic and congestion, the packets are quietly dropped. Some upper-level protocols can detect data loss, others cannot.

Quality of service (QoS) is the phrase commonly associated with the concept of actively managing network bandwidth. In this scenario, all network elements (for example, hosts, applications, and routers) and all network protocol layers cooperate to ensure consistent traffic and service end-to-end in a network. Network bandwidth for real-time applications is reserved, while sufficient bandwidth remains for best-effort traffic.

The major network QoS components in this operating system are as follows:

- Traffic Control subsystem — Provides an application data flow with a QoS that approximates Best Effort delivery through unloaded network interfaces.

Traffic control is supported on the Ethernet and FDDI interfaces.

- Resource ReSerVation Protocol (RSVP) — Provides a mechanism to reserve bandwidth on the local system and through the network. On this operating system, RSVP is implemented in the form of the `rsvpd` daemon. The `rsvpd` daemon uses the Traffic Control subsystem to install and modify flows and filters for a specific network interface.
- RSVP Application Programming Interface (RAPI) — Enables a local application that requires enhanced QoS to communicate with the `rsvpd` daemon. Using the RAPI routines, an application can make resource (bandwidth) reservations on the local system or advertise services to other nodes in the network, or both. See the *Network Programmer's Guide* for a description of the RAPI routines.

2.11.1 Managing the Traffic Control Subsystem

The Traffic Control subsystem performs the following tasks:

- Implements an admission control mechanism that maintains interface parameters, such as the device's peak output rate, the percentage of bandwidth that can be reserved, and the maximum number of concurrent flows.
- Ensures that applications do not pace data at a rate faster than allowed.
- Interfaces with the `rsvpd` daemon and the `iftcntl` command to install and remove flows and filters.
- Matches all outgoing packet headers with any existing filter specifications to determine on which output queue to place the packets.

See `iftcntl(8)` for more information.

The `rsvpd` daemon requires that traffic control be enabled on the local system in order to install and modify flows and filters for a specific network interface. To enable traffic control on your local system, check that the `ether_cl_scheduler` system attribute is enabled (set to 1). If it is not enabled, enable it by using the `sysconfig` command or `dxkerneltuner`. Then, reboot the system.

2.11.2 Managing RSVP

RSVP assigns QoS to specific IP data flows or sessions, which can be either multipoint-to-multipoint or point-to-point. In order to receive data packets for a particular multicast session, a host must have joined the corresponding IP multicast group. A given session may have multiple senders and if the destination is a multicast address, multiple receivers.

The `rsvpd` daemon performs the following functions:

- Listens for incoming RSVP messages

- Communicates with RSVP-enabled applications on the local host through RAPI
- Interfaces with the operating system's Traffic Control subsystem

See `rsvpd(8)` for more information.

2.11.2.1 Starting and Stopping rsvpd

To start the `rsvpd` daemon, enter the following command:

```
# /usr/sbin/rsvpd
```

If you want to start the daemon automatically at system boot time, include the command in the `/etc/inet.local` file. See `rsvpd(8)` for more information on the daemon and its options.

To stop the `rsvpd` daemon, enter the following command:

```
# kill -9 `cat /var/run/rsvdpd.pid`
```

The `rsvdpd` daemon does not start or stop any applications during its startup or shutdown procedures. It also does not maintain any on-disk configuration information about applications. Whenever the `rsvdpd` daemon starts, it has no information about previous reservations.

Typically all daemons on the operating system are started or stopped together, as the system changes run levels. But applications must correctly handle situations where they start before the `rsvdpd` daemon, or are running while the `rsvdpd` daemon is restarted. In these situations, local applications need to reinitiate communications with the `rsvdpd` daemon.

2.11.2.2 Adding and Deleting Network Interfaces

When you add or delete a network interface on your system, you must stop and restart the `rsvdpd` daemon in order for it to update its table of available interfaces. Enter the following commands:

```
# kill -9 `cat /var/run/rsvdpd.pid`
# /usr/sbin/rsvpd
```

2.11.2.3 Displaying RSVP Session Information

You can display RSVP session information on routing systems or end systems to determine if RSVP is working correctly on your system. RSVP session information will show you if connections are being set up and if reservations are being honored.

To monitor active RSVP sessions on the local system, enter the following command:

```
# /usr/sbin/rsvpsstat
```

By default, the `rsvpstat` command displays a list of all RSVP sessions, sender and receiver, active on this system. Information includes the session number, destination address, IP protocol, port number, and the number of PATH and RESV states for the session.

To display sender information, including the contents of the actual PATH message from the sender, enter the following command:

```
# /usr/sbin/rsvpstat -Sv
```

To display receiver information, including the contents of the actual RESV message from the receiver, enter the following command:

```
# /usr/sbin/rsvpstat -Rv
```

See `rsvpstat(8)` for more information.

Internet Protocol Version 6

In the early 1990s the members of the Internet community realized that the address space and certain aspects of the current TCP/IP architecture were not capable of sustaining the explosive growth of the Internet. The problems included the exhaustion of the Internet address space, the size of routing tables, and requirements for new technology features.

The Internet Engineering Task Force (IETF) made several efforts to both study and improve the use of the 32-bit Internet Protocol (IPv4) addresses. They also tackled the longer-term goal of identifying and replacing protocols and services that would limit growth.

These efforts identified the 32-bit addressing architecture of IPv4 as the principal problem, in terms of router overhead and of network administration. In addition, IPv4 addresses were often unevenly allocated in blocks that were too large or too small, and therefore difficult to change within any existing network.

In July 1994, the Internet Protocol Next Generation (IPng) directorate announced the Internet Protocol Version 6 (IPv6) as the replacement network layer protocol, and IETF working groups began to build specifications. See RFC 1752, “The Recommendation for the IP Next Generation Protocol,” for additional information on the IPv6 protocol selection process.

IPv6 is both a completely new network layer protocol and a major revision of the Internet architecture. As such, it builds upon and incorporates experiences gained with IPv4. This chapter describes the following:

- Terms
- IPv6 addressing
- IPv6 environment
- IPv6 configuration
- Post-configuration tasks
- IPv6 logging

For troubleshooting information, see Section 15.4.

3.1 Terms

The following terms are used in this chapter:

node

Any system that uses the IPv6 protocol to communicate.

router

A node that forwards IPv6 packets addressed to other nodes. These systems typically have more than one network interface card (NIC) installed and configured.

host

Any node that is not a router.

link

A medium or facility over which nodes communicate with each other at the link layer. Examples include Ethernet, FDDI, PPP links, or internet layer tunnels.

interface

A node's attachment to a link, which is usually assigned an IPv6 address or addresses. This can be a physical NIC (for example, `tu0` or `le0`) or virtual network interface (for example, `ppp0`).

3.2 IPv6 Addressing

This section is intended for those administrators who need an introduction to IPv6 addressing. If you already know this information, you may skip to Section 3.3.

The most noticeable feature of IPv6 is the IPv6 address itself. The address size is increased from 32 bits to 128 bits. This section describes the following:

- Address text representation
- Address autoconfiguration
- Address resolution
- Address assignment

3.2.1 Address Text Representation

You can use the following syntax to represent IPv6 addresses as text strings:

`x:x:x:x:x:x`

The `x` is a hexadecimal value of a 16-bit piece of the address. For example, the following addresses are IPv6 addresses:

```
FEDC:BA98:7654:3210:FEDC:BA98:7654:3210
```

```
1070:0:0:0:0:800:200C:417B
```

IPv6 addresses can contain long strings of zero (0) bits. To make it easier to write these addresses, you can use the double colon characters (: :) one time in an address to represent 1 or more 16-bit groups of zeros. For example, you can compress the second IPv6 address example as follows:

```
1070::800:200C:417B
```

Alternatively, you can use the following syntax to represent IPv6 addresses in an environment of both IPv4 and IPv6 nodes:

x:x:x:x:d.d.d.d

In this case, *x* is a hexadecimal value of a 16-bit piece of the address (six high-order pieces) and *d* is a decimal value of an 8-bit piece of address (four low-order pieces) in standard, dotted-quad IPv4 form. For example, the following addresses are IPv6 addresses:

```
0:0:0:0:0:0:13.1.68.3
```

```
0:0:0:0:0:FFFF:129.144.52.38
```

When compressed, these addresses are as follows:

```
::13.1.68.3
```

```
::FFFF:129.144.52.38
```

Like IPv4 address prefixes, IPv6 address prefixes are represented using the Classless Inter-Domain Routing (CIDR) notation. This notation has the following format:

ipv6-address/prefix-length

For example, you can represent the 60-bit hexadecimal prefix 12AB00000000CD3 in any of the following ways:

```
12AB:0000:0000:CD30:0000:0000:0000/60
```

```
12AB::CD30:0:0:0:0/60
```

```
12AB:0:0:CD30::/60
```

3.2.2 Types of Addresses

There are three types of IPv6 addresses:

- Unicast
- Anycast
- Multicast

Note

Unlike IPv4, IPv6 does not define a broadcast address. To get the function of a broadcast address, use a multicast address with link-local scope (see Section 3.2.2.2).

The following sections describe only the unicast and multicast address types and provide examples.

3.2.2.1 Unicast Address

A unicast address is an identifier for a physical network interface. Packets sent to a unicast address are delivered to the node containing the interface identified by the address.

Unicast addresses typically have the following format:

ZK-1291U-AI

This address typically consists of a 64-bit prefix followed by a 64-bit interface ID as follows:

ZK-1292U-AI

An interface ID identifies an interface on a link. The interface ID is required to be unique on a link, but may also be unique over a broader scope. In many cases, an interface's ID is derived from its link-layer address. The same interface ID may be used on multiple interfaces on a single node.

The following list describes commonly used unicast addresses and their values:

Unspecified address

Indicates the absence of an address, and is never assigned to an interface. The unspecified address has the value `0:0:0:0:0:0:0:0` in the normal form or `::` in the compressed form.

Loopback address

Used by a node to send IP datagrams to itself, and is typically assigned to the loopback interface. The IPv6 loopback address has the value `0:0:0:0:0:0:0:1` in the normal form or `::1` in the compressed form.

IPv6 addresses with embedded IPv4 addresses

Used in mixed IPv4 and IPv6 environments, and can be either of the following:

- IPv4-compatible IPv6 address

Used by IPv6 nodes to tunnel IPv6 packets across an IPv4 routing infrastructure. The IPv4 address is carried in the low-order 32-bits. The format of this address is as follows:

ZK-1293U-AI

Note

Do not use IPv4-compatible IPv6 addresses in DNS or the local `/etc/ipnodes` file.

- IPv4-mapped IPv6 address

Used to represent an IPv4 address and to identify nodes that do not support IPv6 (IPv4-only nodes). It is not used in an IPv6 packet. The format of this address is as follows:

ZK-1294U-AI

Local-use IPv6 unicast addresses

Can be either of the following:

- Link-local

Used for addressing on a single link when performing address autoconfiguration, neighbor discovery, or when no routers are present. The format of this address is as follows:

ZK-1295U-AI

- Site-local

Used for sites or organizations that are not connected to the global Internet. The format of this address is as follows:

ZK-1296U-AI

If you plan on using site-local addresses, be aware of the following guidelines:

- Do not connect a single node to multiple sites.

- Do not use site-local addresses in the global DNS (the addresses cannot be visible outside the site).
- Dynamic DNS updates for site-local addresses are not supported.
- Do not advertise or propagate routes containing site-local prefixes outside the site.

3.2.2.2 Multicast Address

A multicast address is an identifier for a group of nodes, similar to an IPv4 multicast address. Multicast addresses have the following format:

ZK-1303U-AI

In the preceding address format, the fields have the following definition:

11111111 Identifies the address as multicast.

Flags Can be either of the following values: 0000, which indicates a permanently-assigned (well-known) multicast address, or 0001, which indicates a nonpermanently-assigned (transient) multicast address.

Scope Indicates the scope of the multicast group. The following table lists the scope values:

Value (Hex)	Scope
1	Node-local
2	Link-local
5	Site-local

	8	Organization-local
	E	Global
<hr/>		
Group ID	Identifies the multicast group within the specified scope.	

Table 3–1 lists some well-known multicast addresses.

Table 3–1: Well-known Multicast Addresses

Multicast Address	Meaning
FF02::1	All nodes (link-local)
FF02::2	All routers (link-local)
FF02::9	All RIPng routers (link-local)

3.2.3 Address Prefixes

Each IPv6 address has a unique pattern of leading bits that indicates its address type. These leading bits are named the **Format Prefix**. Table 3–2 lists some of the IPv6 address types and their prefixes.

Table 3–2: IPv6 Address Types and Prefixes

Address Type	Prefix
Aggregatable Global Unicast	2000::/3
Link-local	FE80::/10
Site-local	FEC0::/10
Multicast	FF00::/8

3.2.4 Address Autoconfiguration

The IPv6 address changes have lead to the following definitions for configuring addresses:

- Stateless Address Autoconfiguration
- Dynamic Host Configuration Protocol Version 6 (DHCPv6), which is stateful address autoconfiguration

In the stateless model, nodes learn address prefixes by listening for Router Advertisement packets. Addresses are formed by combining the prefix with a datalink-specific interface identifier, which is typically derived from the datalink address of the interface. This model is favored by administrators

who do not need tight control over address configuration. See RFC 2462 for more information.

In DHCPv6, hosts may request addresses, configuration information and services from dedicated configuration servers. This model is favored by administrators who want to delegate addresses based on a client/server model. The DHCPv6 Internet Drafts are currently undergoing revision. See the Dynamic Host Configuration charter web page at <http://www.ietf.org/html.charter/dhc-charters.html> for more information.

Note

This version of Tru64 UNIX does not currently support DHCPv6.

In both cases, the resulting addresses have associated lifetimes, and systems must be able to acquire new addresses and release expired addresses. Combined with the ability to register updated address information with Domain Name Service (DNS) servers, these mechanisms provide a path towards network renumbering and provide network administrators with control over the use of network addresses without manual intervention on each host on the network.

3.2.5 Address Resolution

The Domain Name System (DNS) provides support for mapping names to IP addresses and mapping IP addresses back to their corresponding names. Because of the increase in size of the IPv6 address, the DNS has the following new features:

- AAAA resource record type. This holds IPv6 addresses, encoded in network byte order. The version of BIND shipped with operating system supports AAAA records. (BIND is the implementation of DNS shipped with Tru64 UNIX.)
- AAAA query. A query for a specified domain name in the Internet class returns all associated AAAA resource records in the response.
- IP6.INT domain for looking up a name for a specified address (address-to-name mapping). An IPv6 address is represented in reverse order as a sequence of 4-bit nibbles separated by dots with the suffix `.IP6.INT` appended. For example, the IPv6 address `4321:0:1:2:3:4:567:89ab` has the following inverse lookup domain name:

`b.a.9.8.7.6.5.0.4.0.0.0.3.0.0.0.2.0.0.0.1.0.0.0.0.0.0.0.1.2.3.4.IP6.INT`

See Section 8.5.1.1 for guidelines on configuring BIND in an IPv6 environment.

3.2.6 Address Assignment

IPv6 addresses are now being deployed by the regional registries. See the IANA web page at <http://www.ipv6.org/iana-ann.html> for more information. In addition, you can contact your Internet Service Provider (ISP) for an IPv6 address.

Because of the need to test various implementations of the IPv6 RFCs, the IETF has defined a temporary IPv6 address allocation scheme. You can assign the addresses in this scheme to hosts and routers for testing IPv6 on the 6bone. See the 6bone home page at the following location for more information on 6bone address allocation and assignment:

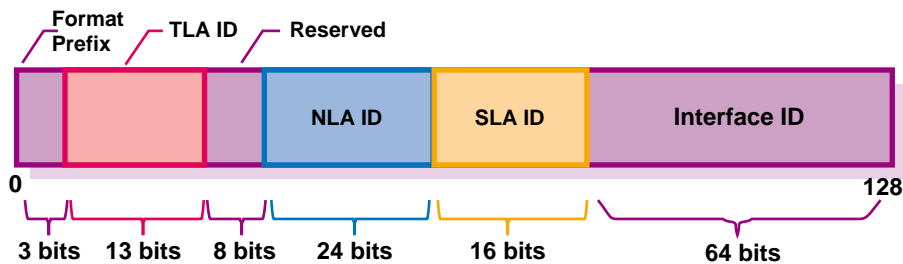

<http://www.6bone.net>

At the present time, the 6bone test addresses are aggregatable global unicast addresses. Contact your 6bone service provider (for example, `gw-6bone@pa.dec.com`) for a 6bone address delegation.

The following sections describe the aggregatable global unicast addresses and the aggregatable testing addresses.

3.2.6.1 Aggregatable Global Unicast Address Format

The aggregatable global unicast address format for IPv6 is designed to support current provider-based aggregation and new exchange-based aggregation. Whether a site connects to a provider or to an exchange, the address format enables efficient route aggregation for either type. Aggregatable global unicast addresses have the following form. See RFC 2374 for additional information.

ZK-1301U-AI

In the preceding address format, the fields have the following definition:

Format Prefix

The Format Prefix. For aggregatable global unicast addresses, the value for this field is 001.

TLA ID

The Top-level Aggregation Identifier.

Reserved

Reserved for future use. At present, set to all zeros (0).

NLA ID

The Next-level Aggregation Identifier. These are assigned by the TLA ID administrator to create an addressing hierarchy and to identify end user sites. Each organization assigned a TLA ID is also assigned 24-bits of NLA ID space whose layout and use is the responsibility of the organization.

SLA ID

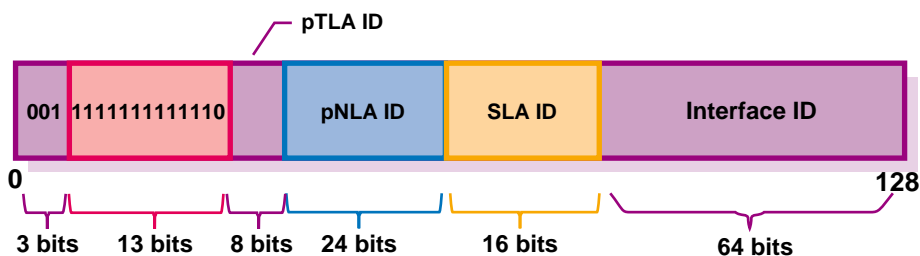

The Site-level Aggregation Identifier. These are used by an end user site to create its own local addressing hierarchy and to identify subnets.

Interface ID

The 64-bit interface identifier of the interface that is connected to the link.

3.2.6.2 Aggregatable Testing Address Format

Aggregatable global unicast addresses for IPv6 testing have the following form. See RFC 2471 for more information on the proposed testing address allocation plan.

ZK-1341U-AI

In the preceding address format, the fields have the following definition:

001

The Format Prefix for aggregatable global unicast addresses.

11111111111110

The 6bone Top-level Aggregation (TLA) Identifier, 0x1FFE, reserved by the Internet Assigned Numbers Naming Authority (IANA), and used temporarily for IPv6 testing.

pseudo Top-Level Aggregation (pTLA) Identifier

The ID assigned by the pTLA ID administrator to define the top level of aggregation (backbone sites) for the 6bone.

pseudo Next-level Aggregation (pNLA) Identifier

The ID assigned by the pTLA ID administrator to create an addressing hierarchy and to identify end user sites on the 6bone network.

Site-level Aggregation (SLA) Identifier

The ID assigned by an end user site to create its own local addressing hierarchy and to identify subnets.

Interface ID

The 64-bit interface identifier of the interface that is connected to the link.

For the most recent information about pTLA and pNLA assignments, see the 6bone home page at the following location:

<http://www.6bone.net>

3.3 IPv6 Environment

This section shows some sample IPv6 configurations. Select a configuration that most closely matches the environment into which you want to configure IPv6 on your system. These configurations are used again in Section 3.4 to describe how to configure selected systems in each configuration.

See the *Technical Overview* for a list of commands and daemons that are supported in an IPv6 environment. See the *Release Notes* for a list of network interfaces that are supported for IPv6.

Figure 3-1 shows a simple LAN configuration in which Host A and Host B communicate using IPv6.

Figure 3–1: Simple Host-to-Host Configuration

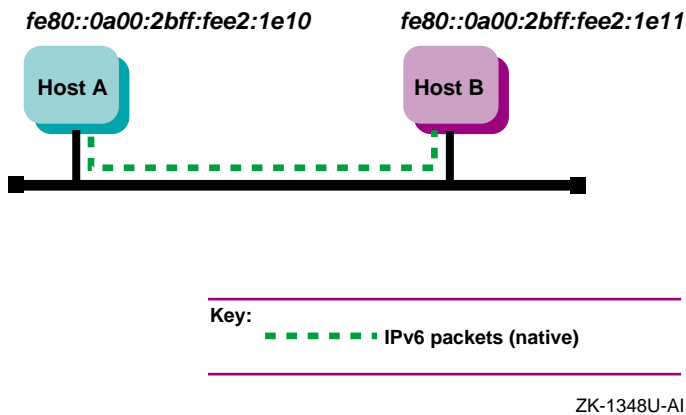

Figure 3–2 shows a simple LAN configuration in which Host A, Host B, and Router A communicate using IPv6 and in which Host A and Host B obtain global addresses from Router A.

Figure 3–2: Host-to-Host with Router Configuration

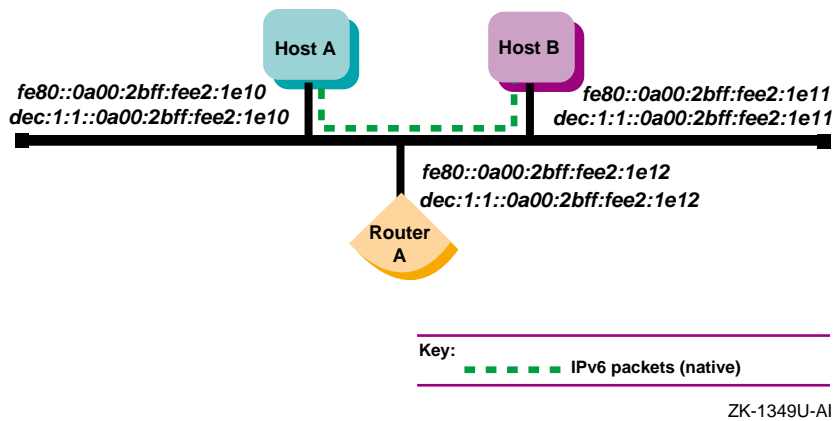

Figure 3–3 shows a configuration in which two IPv6 networks are connected through an IPv6 router, Router A.

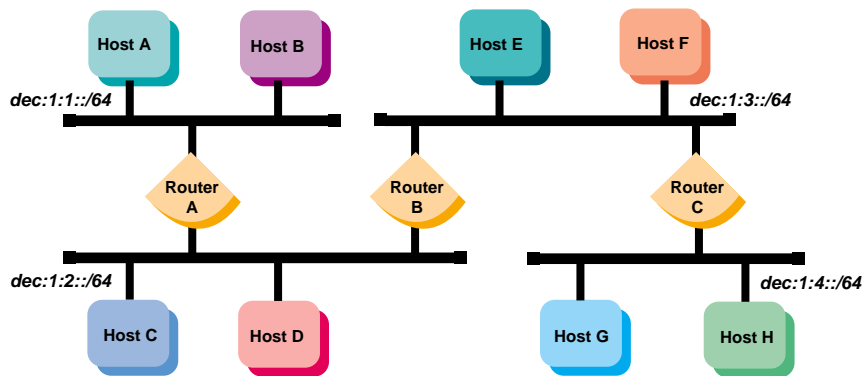

Figure 3–3: IPv6 Network-to-IPv6 Network with Router Configuration

ZK-1350U-AI

Figure 3–4 shows a configuration in which four IPv6 networks are connected using three routers. The three routers exchange routing information with each other using the RIPng protocol.

Figure 3–4: Multiple IPv6 Networks and Multiple Routers Configuration

ZK-1351U-AI

Figure 3–5 shows a configuration in which Host A and Host B, connected to an IPv4 network, communicate using IPv6 through an IPv4 tunnel.

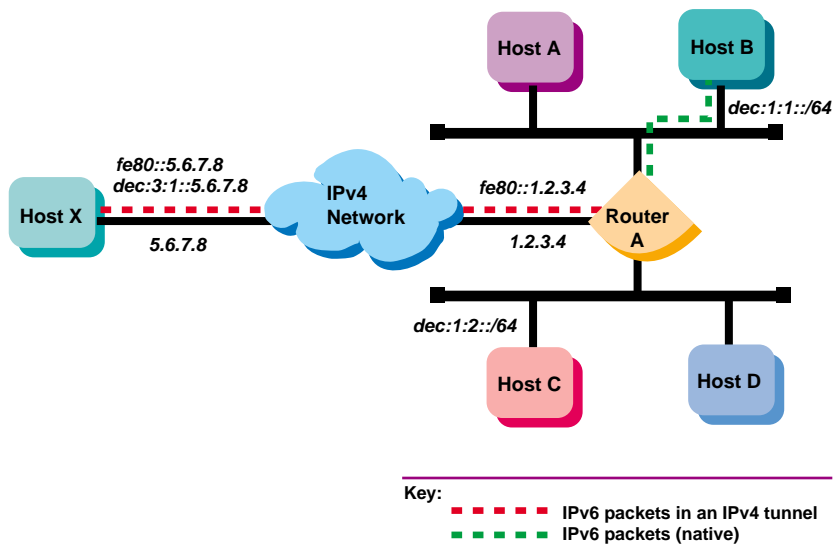

Figure 3–5: Host-to-Host over Tunnel Configuration

ZK-1298U-AI

Figure 3–6 shows a configuration in which Host X is connected to an IPv4 network and Router A, an IPv6 router, is connected to the same IPv4 network and also is connected to two IPv6 networks. Host X communicates with Host B using IPv6 through an IPv4 tunnel between Host X and Router A.

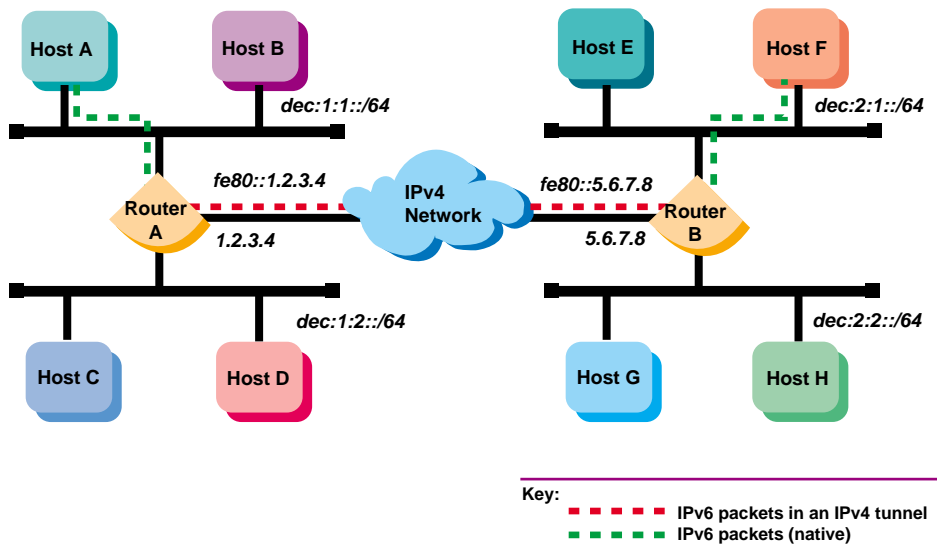

Figure 3–6: Host-to-Router over Tunnel Configuration

ZK-1347U-AI

Figure 3–7 shows a configuration in which four IPv6 networks are connected through two routers and an IPv4 network. Host A communicates with Host F through an IPv4 tunnel between router A and router B.

Figure 3–7: IPv6 Network-to-IPv6 Network over Tunnel Configuration

ZK-1299U-AI

3.4 Planning IPv6

This section describes those tasks that you need to do before configuring IPv6.

3.4.1 Verifying IPv6 Support in the Kernel

Verify that the IP Version 6 (IPV6) and IP-in-IP Tunneling (IPTUNNEL) support is in the kernel by issuing the following commands:

```
# sysconfig -q ipv6
# sysconfig -q iptunnel
```

If neither the `ipv6:` nor `iptunnel:` subsystem attributes are displayed, do the following:

1. Build a new kernel by using the following command:

```
# doconfig -c SYSTEM_NAME
```

Choose the IPV6 and IPTUNNEL options in addition to any other options that you want.

2. Save the original kernel, then move the new kernel to the root directory.

```
# mv /vmunix /vmunix.save
# mv /sys/SYSTEM_NAME/vmunix /vmunix
```

3. Reboot the system. Make sure there are no other users on the system. Use a command similar to the following:

```
# shutdown -r +5 "Adding IPv6 and IPTUNNEL kernel options ..."
```

You are now ready to configure your system to communicate in an IPv6 network environment.

3.4.2 Preparing for the Configuration

After you verify IPv6 support in the kernel, you configure your system to communicate in an IPv6 network environment by running the IPv6 configuration utility, `ip6_setup`. The `ip6_setup` utility enables you to configure the following:

- IPv6 host
- IPv6 router

When you run the `ip6_setup` configuration utility, it gathers information from the system and prompts you for additional configuration information.

Before you configure the IPv6 network software, you must gather information about your system and network environment. Figure 3-8 shows the Configuration Worksheet. The following sections describe the information that you need to record on the worksheet.

If you are viewing this manual on line, you can use the print feature to print a copy of this worksheet.

Figure 3–8: Configuration Worksheet

IPv6 Configuration	
IPv6 router:	<input type="checkbox"/> yes <input type="checkbox"/> no

Next hop address:	_____

IPv6 router

If you want this system to function as an IPv6 router, check YES; otherwise, check NO. If you check NO, the system is configured as an IPv6 host.

An IPv6 router can advertise address prefixes to all hosts on connected links (for example, a LAN and a configured tunnel) and forward packets toward their destinations. Packets can be forwarded directly on link or over IPv4 tunnels.

DNS/BIND automatic updates (hosts only)

If you want this system to record its addresses in the DNS/BIND database automatically, check YES; otherwise, check NO. If you check YES, you must configure your system as a DNS/BIND client and your DNS/BIND server must support dynamic updates to the DNS database. See Section 8.5.1.1 for information on configuring your DNS/BIND server.

IPv6 interfaces

Enter the device names of the network interface to the IPv6 network. For example, `le0` and `fta0`. If you are creating a configured tunnel only on your system, enter `none`.

IPv6 routing over PPP (routers only)

If you want IPv6 routing to run over a PPP interface, check YES; otherwise, check NO. See `ppp_manual_setup(7)` for information on configuring a PPP interface.

Configured tunnel

If you want IPv6 to run over a configured IPv4 tunnel, check YES; otherwise, check NO. A configured tunnel has one source and one destination in an IPv4 network. Use configured tunnels instead of automatic tunnels. You can define multiple configured tunnels.

Automatic tunnel

If you want to configure IPv6 to run over IPv4 automatic tunnels, check YES; otherwise, check NO.

Manual routes

If you want to configure routes to other systems manually, check YES; otherwise, check NO.

On a router, you might want to configure static routes if one of the following conditions is true:

- You want a configured tunnel and you are not advertising an address prefix on the tunnel link.
- You want a configured tunnel and the router at the other end of the tunnel is not running the RIPng protocol.
- Your system is not running the RIPng protocol.

On a host, you might want to configure static routes if you want a configured tunnel to a router and the router is not advertising itself as a default router on the tunnel link.

Start IPv6

If you want to start IPv6 directly from the configuration utility, `ip6_setup`, check YES. If you want to start IPv6 during the next system boot, check NO.

3.4.2.1 DNS/BIND

Domain name

The fully qualified domain name for your node. This consists of the host name and the DNS/BIND domain name (for example, `host1.subdomain.example`).

3.4.2.2 Configured Tunnel

Interface

The name of the configured tunnel interface (for example, `ipt0`, `ipt1`). The `ip6_setup` script supplies this value.

Destination IPv4 address

The remote node's IPv4 address (the remote end of the tunnel).

Source IPv4 address

Your node's IPv4 address (this end of the tunnel).

RIPng

If your system is a router and you want the router to run the RIPng protocol on the tunnel link to exchange IPv6 routing information with a router at the remote end of the tunnel, check YES; otherwise, check NO.

Address prefix

If your system is a router and you want to advertise address prefixes to the node at the remote end of the tunnel, enter a 64-bit prefix; otherwise, write DONE.

If your system is an IPv6 host and the router at the remote end of the tunnel is not advertising an address prefix, enter a 64-bit prefix to be configured on the tunnel interface.

3.4.2.3 Router

Interface

The name of the interface (LAN, PPP, or configured tunnel) on which you want to run the RIPng protocol or advertise an address prefix.

RIPng

If you want the router to run the RIPng protocol on the specified interface and to exchange IPv6 routing information with other routers on the link (LAN, PPP, or configured tunnel), check YES; otherwise, check NO.

Address prefix

If you want to advertise address prefixes to all hosts on the link, enter a 64-bit prefix; otherwise, write DONE.

If you write DONE, the router will not advertise an address prefix. All hosts must obtain their prefix information from another source.

Prefixes in IPv6 define a subnet, and are typically configured on a router for a specific link by the network administrator. The router advertises this prefix to all nodes connected to that link, along with the length of the prefix, whether the prefix is on link (that is, a neighbor), whether the prefix can also be used for stateless address configuration, and the length of time the prefix is valid.

3.4.2.4 Manual Routes

Destination prefix

The address prefix of a remote IPv6 network. The address prefix contains a Classless Inter-Domain Routing (CIDR)-style bit length, for example, 5F00::/8. If you want to use the default route, write DEFAULT.

Interface

The name of the interface through which you are sending traffic to the remote IPv6 network.

Next hop address

The IPv6 address of the first router in the path to the destination prefix. Write the link local address of the router. If the connection to the router is over an IPv4 tunnel, write the link local IPv6 address of the remote tunnel endpoint.

3.4.3 Configuring Systems in Sample IPv6 Configurations

This section describes each sample configuration presented in Section 3.3 and shows how selected systems are configured in each example. In some cases, this section presents additional options for you to consider in the configuration.

3.4.3.1 Simple Host-to-Host Configuration

In Figure 3–1, Host A and Host B use IPv6 link-local addresses. By default, the `ip6_setup` configuration utility automatically creates a link-local address for your system. The following is a sample completed worksheet for Host A:

IPv6 Configuration		
IPv6 router:	<input type="checkbox"/> yes	<input checked="" type="checkbox"/> no
DNS/BIND automatic updates:	<input type="checkbox"/> yes	<input checked="" type="checkbox"/> no
IPv6 interfaces:	tu0	
Configured tunnel:	<input type="checkbox"/> yes	<input checked="" type="checkbox"/> no
Automatic tunnel:	<input type="checkbox"/> yes	<input checked="" type="checkbox"/> no
Manual routes:	<input type="checkbox"/> yes	<input checked="" type="checkbox"/> no
Start IPv6:	<input checked="" type="checkbox"/> yes	<input type="checkbox"/> no

After configuring IPv6 on Host A, you edit the `/etc/ipnodes` file and put the link-local address for Host B in it. The configuration process for Host B in this configuration is similar to Host A's.

With this configuration, no global address prefix is advertised on the LAN. If you want to advertise a global address prefix, you could either configure one of the nodes as a router by using `ip6_setup` or add an IPv6 router to the LAN configuration. An IPv6 router advertises a global prefix on the link.

You can use the `netstat -in` command to view a local node's link-local and global addresses.

If you were on Host A and wanted to connect to Host B using the `telnet` command, the format of the command is as follows:

```
# telnet fe80::0a00:2bff:fee2:1e11
```

Instead of specifying the link-local address, place the address and the node name in the `/etc/ipnodes` file. Then, use the node name as the argument to the `telnet` command.

3.4.3.2 Host-to-Host with Router Configuration

In Figure 3–2, Host A and Host B are on LAN with Router A. In this case, Router A advertises the global address prefix `dec:1:1::/64` on the LAN. Host A and Host B use this address prefix to create global IPv6 addresses.

See Section 3.2.6 for more information on obtaining experimental testing addresses. The following is a sample completed worksheet for Router A:

IPv6 Configuration	
IPv6 router:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
DNS/BIND automatic updates:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
IPv6 interfaces:	<u>tu0</u>
Configured tunnel:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Automatic tunnel:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Manual routes:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Start IPv6:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
Router	
Interface:	<u>tu0</u>
RIPng:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Address prefix:	<u>dec:1:1::/64</u>
Interface:	_____
RIPng:	<input type="checkbox"/> yes <input type="checkbox"/> no
Address prefix:	_____

After configuring IPv6 on Router A, you can edit the `/etc/ipnodes` file and add the global addresses for the other nodes. You would also do this on Host A and Host B. Alternatively, you could establish DNS/BIND in your network using the global addresses.

If you added a DNS/BIND server with dynamic updates enabled on the network, the worksheet for Host A would have the following information:

DNS/BIND automatic updates:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
DNS/BIND	
Domain name:	<u>hosta.corp.example</u>

3.4.3.3 IPv6 Network-to-IPv6 Network with Router Configuration

In Figure 3–3, two IPv6 networks are connected to each other through Router A and its multiple interfaces. The following is a sample completed worksheet for Router A:

IPv6 Configuration	
IPv6 router:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
DNS/BIND automatic updates:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
IPv6 interfaces:	<u>tu0</u> <u>tu1</u>
Configured tunnel:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Automatic tunnel:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Manual routes:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Start IPv6:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no

Router	
Interface:	<u>tu0</u>
RIPng:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Address prefix:	<u>dec:1:1::/64</u>
<hr/>	
Interface:	<u>tu1</u>
RIPng:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Address prefix:	<u>dec:1:2::/64</u>

3.4.3.4 Multiple IPv6 Networks and Multiple Routers Configuration

In Figure 3–4, four IPv6 networks are interconnected to each other using the three routers. In this configuration, the routers must exchange routing information in order for the routers to learn the routes to other subnets in the network. To accomplish this, each router must run the RIPng protocol. The following is a sample completed worksheet for Router A:

IPv6 Configuration	
IPv6 router:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
DNS/BIND automatic updates:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
IPv6 interfaces:	<u>tu0</u> <u>tu1</u>
Configured tunnel:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Automatic tunnel:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Manual routes:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Start IPv6:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no

Router	
Interface:	<u>tu0</u>
RIPng:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
Address prefix:	<u>dec:1:1::/64</u>
<hr/>	
Interface:	<u>tu1</u>
RIPng:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
Address prefix:	<u>dec:1:2::/64</u>

The worksheets for the other routers are similar.

worksheet for Host X when Router A is advertising itself as the default router for the tunnel link and advertising a global address prefix on the tunnel link:

IPv6 Configuration

IPv6 router: yes no
 DNS/BIND automatic updates: yes no
 IPv6 interfaces: none
 Configured tunnel: yes no
 Automatic tunnel: yes no
 Manual routes: yes no
 Start IPv6: yes no

Configured Tunnel

Interface: ipt0
 Destination IPv4 address: 5.6.7.8
 Source IPv4 address: 1.2.3.4
 RIPng: yes no
 Address prefix: _____

If Router A is not advertising a global address prefix on the tunnel link, the value `dec:3:1::/64` would be in the Address prefix field in Configured Tunnel section of the Host X worksheet. If Router A is not advertising itself as the default router for the tunnel link, the following information would also be on the Host X worksheet:

Manual routes: yes no

Manual Routes

Destination prefix: default
 Interface: ipt0
 Next hop address: fe80::1.2.3.4

The following is a sample completed worksheet for Router A when Router A is advertising a global address prefix on the tunnel link:

IPv6 Configuration	
IPv6 router:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
DNS/BIND automatic updates:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
IPv6 interfaces:	<u>tu0</u> <u>tu1</u> _____
Configured tunnel:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
Automatic tunnel:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Manual routes:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Start IPv6:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
Configured Tunnel	
Interface:	<u>ipt0</u>
Destination IPv4 address:	<u>5.6.7.8</u>
Source IPv4 address:	<u>1.2.3.4</u>
RIPng:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Address prefix:	<u>dec:3:1::/64</u>

If Router A is not advertising a global prefix on the tunnel link, the following information would be on the Router A worksheet. Note the manual route to Host X. Instead of specifying a destination network prefix, you specify the host route, `dec:3:1::5.6.7.8`, to Host X. The next hop is the link-local IPv6 address of Host X's tunnel interface, `fe80::5.6.7.8`.

Manual routes:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
Manual Routes	
Destination prefix:	<u>dec:3:1::5.6.7.8</u>
Interface:	<u>ipt0</u>
Next hop address:	<u>fe80::5.6.7.8</u>

3.4.3.7 IPv6 Network-to-IPv6 Network over Tunnel Configuration

In Figure 3–7, Host A communicates with Host F over an configured tunnel through an IPv4 network. The host configuration is similar to that of Host A in Section 3.4.3.1. All nodes automatically use their default router in order to communicate with nodes on other networks. The following is a sample completed worksheet for Router A:

IPv6 Configuration	
IPv6 router:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
DNS/BIND automatic updates:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
IPv6 interfaces:	<u>tu0</u> <u>tu1</u> _____
Configured tunnel:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
Automatic tunnel:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Manual routes:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Start IPv6:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
Configured Tunnel	
Interface:	<u>ipt0</u>
Destination IPv4 address:	<u>5.6.7.8</u>
Source IPv4 address:	<u>1.2.3.4</u>
RIPng:	<input checked="" type="checkbox"/> yes <input type="checkbox"/> no
Address prefix:	_____
Router	
Interface:	<u>tu0</u>
RIPng:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Address prefix:	<u>dec:1:1::/64</u>
Interface:	<u>tu1</u>
RIPng:	<input type="checkbox"/> yes <input checked="" type="checkbox"/> no
Address prefix:	<u>dec:1:2::/64</u>

You do not have to run RIPng on the `tu0` and `tu1` interfaces because there are no routers attached to the interfaces.

The configuration of Router B is similar, except that the source and destination addresses for the configured tunnel would be `1.2.3.4` and `5.6.7.8`, respectively, and the address prefixes advertised on `tu0` and `tu1` would be `dec:2:1::/64` and `dec:2:2::/64`, respectively.

Note

If the routers were not configured to use RIPng over the tunnel interface, each router would then need to specify a manual route to the other.

3.5 Configuring IPv6 on Your System

This section describes how to configure your system as either an IPv6 host or an IPv6 router.

3.5.1 Configuring an IPv6 Host

To configure an IPv6 host, do the following:

1. Log in as superuser.
2. Invoke the `ip6_setup` utility by entering the following command:

```
# /usr/sbin/ip6_setup
```

The utility displays a status message.
3. Press Enter to indicate that you want to configure the system as an IPv6 host and not as a router.
4. Indicate whether you want your DNS/BIND client to update IPv6 addresses in the DNS/BIND name database automatically.
If you want to update IPv6 addresses in the DNS/BIND name database automatically, enter `y` and press Enter; if you do not, press Enter and go to step 6.
5. Enter the IPv6 fully qualified domain name and press Enter.
6. Enter the names of the IPv6 LAN interfaces to use and press Enter. Separate multiple names by a space character. If you want to use the default, press Enter. If you are configuring a configured tunnel only, enter `none`.
7. Indicate whether you want to create a configured tunnel or additional configured tunnels.
If you want to create a configured tunnel or additional configured tunnels, enter `y` and press Enter; otherwise, press Enter and go to step 11.
8. Enter the tunnel's destination IPv4 address and press Enter.
If you are finished creating configured tunnels, enter `Done` and press Enter. Go to step 11.
9. Enter the tunnel's source IPv4 address and press Enter. If you want to use the default, press Enter.
10. Indicate whether the host is to use an IPv6 address prefix on the tunnel interface.
If you want the host to use an IPv6 address prefix because a router is not advertising a global address prefix, enter the prefix and press Enter. Enter as many prefixes as you want. When you are finished entering prefixes for the interface, enter `Done` and press Enter. Go to step 8.
If you do not want the host to use an IPv6 address prefix on the tunnel interface, enter `Done` and press Enter. Go to step 8.
11. Indicate whether you want to configure an automatic tunnel.

If you want to configure an automatic tunnel, enter `y` and press Enter; otherwise, press Enter.

12. Indicate whether you want to define manual routes to an adjacent router or remote IPv6 network.

If you want to manually define routes, enter `y` and press Enter.

If you do not want to manually define routes, enter `n` and press Enter. Go to step 16.

13. Enter the IPv6 address prefix of the remote IPv6 network and press Enter. When you are finished entering manual routes, enter `Done` and press Enter; go to step 16.
14. Enter the name of the interface through which you will send traffic to the remote IPv6 network and press Enter.
15. Enter the link-local IPv6 address of the first router in the path to the destination network and press Enter. This address together with the IPv6 address prefix constitute the static routing table entry. Go to step 13.
16. The `ip6_setup` utility displays the configuration information and asks you to indicate whether you want to update the current startup procedures with the new configuration information.
If you are not satisfied with the configuration, enter `n` and press Enter. The utility ends immediately without changing any of the current configuration files.
If you are satisfied with the configuration, enter `y` and press Enter. The `ip6_setup` utility updates the `/etc/rc.config` and `/etc/routes` files with the IPv6 configuration information.

17. If IPv6 is not currently running on your system, indicate whether you want to start IPv6 now.

If you want to start IPv6 now, press Enter. The `ip6_setup` utility starts IPv6.

If you do not want to start IPv6 now, enter `n` and press Enter. IPv6 will start during the next system boot.

If IPv6 is currently running, indicate whether you want to restart it now.

The `/etc/rc.config` file contains configuration information used by the system startup scripts to start IPv6.

3.5.2 Configuring an IPv6 Router

To configure an IPv6 router, do the following:

1. Log in as superuser.

2. Invoke the `ip6_setup` utility by entering the following command:

```
# /usr/sbin/ip6_setup
```

The utility displays a status message.

3. Enter `y` and press Enter to configure the system as an IPv6 router.
4. Enter the names of the IPv6 LAN interfaces to use and press Enter. Separate multiple names by a space character. If you want to use the default, press Enter. If you are configuring a configured tunnel only, enter `none`.

Note

The next two steps are used when configuring IPv6 LAN interfaces, IPv6 over PPP interfaces, and IPv6 over IPv4 configured tunnel interfaces. Follow the directions carefully.

5. Indicate if the router is to run the RIPng protocol on the designated interface.
If you want to run the RIPng protocol, press Enter; if you do not, enter `n` and press Enter.
6. Indicate if the router is to advertise an IPv6 address prefix on the designated interface.
If you want the router to advertise an IPv6 address prefix, enter the prefix and press Enter. Enter as many prefixes as you want. When you are finished entering prefixes for the interface, enter `Done` and press Enter.
If you do not want the router to advertise an IPv6 address prefix on the designated interface, enter `Done` and press Enter.
If you are configuring additional LAN interfaces, go to step 5.
If you are configuring PPP interfaces, go to step 8.
If you are configuring IPv6 over IPv4 configured tunnels, go to step 10.
7. Indicate if you want to use IPv6 routing over PPP links.
If you want to use IPv6 routing over PPP links, enter `y` and press Enter; otherwise, press Enter and go to step 9.
8. Enter the name of the PPP interface over which to run IPv6 and press Enter. Go to step 5.
If you are finished entering routing information for PPP interfaces, enter `Done` and press Enter.
9. Indicate if you want to create IPv6 over IPv4 configured tunnels.

If you want to create configured tunnels, enter `y` and press Enter; otherwise, press Enter and go to step 12.

10. Enter the tunnel's destination IPv4 address and press Enter.

If you are finished creating configured tunnels, enter `Done` and press Enter. Go to step 12.

11. Enter the tunnel's source IPv4 address and press Enter. If you want to use the default, press Enter. Go to step 5.

12. Indicate if you want to configure an automatic tunnel.

If you want to configure an automatic tunnel, enter `y` and press Enter; otherwise, press Enter.

13. Indicate if you want to define manual routes to an adjacent router or remote IPv6 network.

If you want to manually define routes, enter `y` and press Enter.

If you do not want to manually define routes, enter `n` and press Enter. Go to step 17.

14. Enter the IPv6 address prefix of the remote IPv6 network and press Enter. When you are finished entering manual routes, enter `Done` and press Enter. Go to step 17.

15. Enter the name of the interface through which you will send traffic to the remote IPv6 network and press Enter.

16. Enter the IPv6 address of the next node in the path to the destination network and press Enter. This address together with the IPv6 address prefix constitute the static routing table entry. Go to step 14.

17. The `ip6_setup` utility displays the configuration information and asks you to indicate whether you want to update the current startup procedures with the new configuration information.

If you are not satisfied with the configuration, enter `n` and press Enter. The utility ends immediately without changing any of the current configuration files.

If you are satisfied with the configuration, enter `y` and press Enter. The `ip6_setup` utility updates the `/etc/rc.config`, `/etc/routes`, and `/etc/ip6rtrd.conf` files with the IPv6 configuration information. You can modify these values as necessary.

18. If IPv6 is not currently running on your system, indicate whether you want to start IPv6 now.

If you want to start IPv6 now, press Enter. The `ip6_setup` utility starts IPv6.

If you do not want to start IPv6 now, enter `n` and press Enter. IPv6 will start during the next system boot.

If IPv6 is currently running, indicate whether you want to restart it now.

The `/etc/rc.config`, `/etc/routes`, and `/etc/ip6rtrd.conf` files contain configuration information used by the system startup procedures to start IPv6. You can edit them to change your configuration.

3.6 Postconfiguration Tasks

After using the `ip6_setup` utility to initially configure IPv6, you might want to do the following:

- Connect to the 6bone network
- Initialize a new interface for IPv6
- Create a configured tunnel
- Add addresses to or delete addresses from an interface
- Add or delete a default router
- Manually add a route for an onlink prefix
- Configure routing support in the kernel
- Edit the run-time configuration file (`/etc/rc.config`)
- Edit the router configuration file (`/etc/ip6rtrd.conf`)
- Tune the `ipv6` and `iptunnel` kernel subsystems

The following sections describe these tasks.

3.6.1 Connecting to the 6bone Network

To connect to the 6bone, choose a 6bone point that appears to be reasonably adjacent to your normal IPv4 paths into the Internet. The 6bone Web site at <http://www.6bone.net> contains information on how to join the 6bone and how to find an attachment point.

If you want to connect to the 6bone through the Compaq Palo Alto, CA site either before or after you configure IPv6 on your host or router, complete the following steps:

1. Register your IPv4 tunnel by sending the IPv4 address of your router to the following address:
`gw-6bone@pa.dec.com`
2. Wait for confirmation that support for your tunnel is configured at Compaq. Compaq will provide an IPv6 global address prefix for you to use at your site and the IPv4 address of the Compaq Palo Alto router.
3. Configure your tunnel by running the `ip6_setup` utility. See Section 3.5.1 for host configuration and Section 3.5.2 for router

configuration. Alternatively, you could run the `iptunnel` command (see Section 3.6.4).

4. Verify that your tunnel is operational by issuing the `ping` command to one of the following Compaq IPv6 nodes:

```
altavista.ipv6.digital.com
ftp.ipv6.digital.com
www.ipv6.digital.com
```

For additional information on connecting to the 6bone, see the 6bone home page:

3.6.2 Initializing a New Interface for IPv6

In some cases, you might want to add a new interface card to your system or change an interface card from one type to another. After the new card is installed, you must initialize it for IPv6 operation. To initialize an interface, use the `ifconfig` command with the following syntax:

```
ifconfig device ipv6 up
```

For LAN interfaces, the `ifconfig` command creates the link-local address (FE80::) and starts Duplicate Address Detection.

For example, to initialize Ethernet interface `ln0` for use with IPv6, enter the following:

```
# ifconfig ln0 ipv6 up
```

To initialize the loopback interface for use with IPv6, enter the following:

```
# ifconfig lo0 ipv6 up
```

To initialize the automatic tunnel interface, enter the following:

```
# ifconfig tun0 ipv6 up
```

This chooses one of the system's IPv4 addresses for use as the tunnel endpoint.

If you are adding the interface card permanently, use the `ip6_setup` utility.

3.6.2.1 Setting the IPv6 Interface Identifier

You can set the IPv6 interface ID at the same time you initialize an interface by using the `ifconfig` command with the `ip6interfaceid` parameter. For example, to initialize Ethernet interface `ln0` for use with IPv6 and set its interface ID to the 64-bit value `0x0123456789abcdef`, enter the following:

```
# ifconfig ln0 ip6interfaceid ::0123:4567:89ab:cdef ipv6 up
```

Although the interface ID is expressed in standard IPv6 address format, only the low order 64 bits are used.

3.6.3 Removing IPv6 from an Interface

Removing IPv6 from an interface removes the IPv6 configuration associated with the interface, including all IPv6 addresses and IPv6 routes through the interface. To remove IPv6 from an interface, use the `ifconfig` command with the following syntax:

```
ifconfig device -ipv6
```

For example, to remove IPv6 from Ethernet interface `ln0`, enter the following:

```
# ifconfig ln0 -ipv6
```

3.6.4 Creating a Configured Tunnel

To create a configured (manual) tunnel, use the `/usr/sbin/iptunnel` command with the following syntax:

```
iptunnel create remote-tunnel-endpoint [local-tunnel-endpoint]
```

For example, to create a tunnel to the remote system `16.20.136.47`, enter the following command:

```
# iptunnel create 16.20.136.47
```

To initialize the tunnel for IPv6 operation, enter the following:

```
# ifconfig ipt0 ipv6 up
```

If you want this change to be permanent, use the `ip6_setup` utility.

3.6.5 Adding an Address to an Interface

To add or assign an IPv6 prefix to an interface and to direct the kernel to automatically append the interface identifier, use the `ifconfig` command with the following syntax:

```
ifconfig interface-name inet6 ip6prefix prefix
```

The following example assigns the address `dec:2::0a00:2bff:fe12:3456` to interface `le0` (the interface ID is `0a00:2bff:fe12:3456`):

```
# ifconfig ln0 inet6 ip6prefix dec:2::/64
```

The `ip6prefix` parameter directs the kernel to automatically append the interface identifier to the address prefix.

To add or assign a full IPv6 address to an interface manually, use the `ifconfig` command with the following syntax:

```
ifconfig interface-name inet6 address
```

The following example assigns the address `dec:2::1` to interface `le0`:

```
# ifconfig ln0 inet6 dec:2::1
```

Note

For IPv6 hosts, the `nd6hostd` daemon configures interface prefixes automatically, depending on the contents of router advertisements.

For IPv6 routers, the `ip6rtrd` daemon configures interface prefixes automatically, depending on the contents of the `/etc/ip6rtrd.conf` file.

3.6.6 Deleting an Address from an Interface

To delete an IPv6 address from an interface manually, use the `ifconfig` command with the following syntax:

```
ifconfig interface-name inet6 delete address
```

For example:

```
# ifconfig ln0 inet6 delete dec:2::1
```

3.6.7 Adding or Deleting a Default Router

To add a default router, use the `route` utility with the following syntax:

```
route add -inet6 default router-address -dev interface
```

For example:

```
# route add -inet6 default fe80::0a00:2bff:fe12:3456 -dev le0
```

To delete a default router, use the `route` utility with the following syntax:

```
route delete -inet6 default router-address -dev interface
```

For example:

```
# route delete -inet6 default fe80::0a00:2bff:fe12:3456 -dev le0
```

Note

For IPv6 hosts, the `nd6hostd` daemon performs the add and delete router operations automatically, depending on the contents of router advertisements.

3.6.8 Manually Adding a Route for an Onlink Prefix

After you manually add an address/prefix to an interface, you can also add a static route so that traffic to other nodes with the same prefix is sent directly to the destination rather than through a router. For example, if the prefix

DEC:5::/64 has been added to the Ethernet interface `le0`, which has been initialized with the link-local address `fe80::0a00:2bff:fe12:3456`, the following command adds a route to neighboring nodes with the same prefix:

```
# route add -inet6 dec:5::/64 fe80::0a00:2bff:fe12:3456 -interface
```

This command specifies that destinations with prefix `dec:5::0/64` are reachable through the interface with address `fe80::0a00:2bff:fe12:3456`. In other words, `dec:5::0/64` is an onlink prefix.

Note

For IPv6 hosts, the `nd6hostd` daemon automatically adds onlink prefixes, based on the contents of router advertisements.

3.6.9 Configuring Routing Support in the Kernel

Before configuring a router, you must enable forwarding by setting the `ipv6forwarding` and `ipv6router` attributes of the `ipv6` kernel subsystem to 1. You set these attributes by entering the following `sysconfig` commands:

```
# /sbin/sysconfig -r ipv6 ipv6forwarding=1
# /sbin/sysconfig -r ipv6 ipv6router=1
```

These commands are typically executed by the system startup scripts on nodes configured as IPv6 routers.

3.6.10 Editing the Run-time Configuration File

After you configure the system, either as an IPv6 host or an IPv6 router, the `/etc/rc.config` file contains information used by the system startup procedures to start IPv6. You can modify this file as appropriate for your configuration by using the `rcmgr` command. The following variables are used by IPv6:

`IPV6="yes|no"`

If set to `yes`, starts IPv6 during system startup.

`IP6DEV_n="dev"`

Specifies an IPv6 device name. The device name must be in the `rc.config` file. The `n` value is an integer number that starts at 0 and increments sequentially for each device.

`IP6IFCONFIG_n_m="string"`

Specifies options and parameters to use on an `ifconfig` command line during system startup. The *n* value is an integer number that corresponds to the number in the `IP6DEV_n` variable. The *m* value is an integer that starts at 0 and increments sequentially for each `ifconfig` line needed for each device.

`NUM_IP6CONFIG="number"`

Specifies the number of IPv6 devices configured.

`IP6ROUTER="yes|no"`

If set to `yes`, configures the node as an IPv6 router. Otherwise, configures the node as a host.

`IP6RTRD="yes|no"`

If set to `yes`, starts the IPv6 router daemon, `ip6rtrd`, during IPv6 startup.

`IP6RTRD_FLAGS="string"`

Specifies a string of options and parameters to use in starting the `ip6rtrd` daemon.

`ND6HOSTD="yes|no"`

If set to `yes`, starts the IPv6 host daemon, `nd6hostd`, during IPv6 startup.

`ND6HOSTD_FLAGS="string"`

Specifies a string of options and parameters to use in starting the `nd6hostd` daemon.

`IPTUNNEL_n="string"`

Specifies a string of options and parameters to use to create a configured tunnel during system startup. This variable is used only when the device specified with the `IP6DEV_n` variable is a configured tunnel (for example, `ipt0`).

Example 3-1 shows sample variables for an IPv6 host in the `/etc/rc.config` file.

Example 3–1: Sample IPv6 Host Configuration Variables

```
IPV6="yes"
IP6DEV_0="tu0"
IP6IFCONFIG_0_0="ipv6 up"
IP6DEV_1="tun0"
IP6IFCONFIG_1_0="ipv6 up"
NUM_IP6CONFIG=2
IP6ROUTER="no"
IP6RTRD="no"
IP6RTRD_FLAGS=""
ND6HOSTD="yes"
ND6HOSTD_FLAGS=" -u -n host1.corp.com"
```

Example 3–2 shows sample variables for an IPv6 router in the `/etc/rc.config` file.

Example 3–2: Sample IPv6 Router Configuration Variables

```
IPV6="yes"
IP6DEV_0="tu0"
IP6IFCONFIG_0_0="ipv6 up"
IP6DEV_1="tu1"
IP6IFCONFIG_1_0="ipv6 up"
NUM_IP6CONFIG=2
IP6ROUTER="yes"
IP6RTRD="yes"
IP6RTRD_FLAGS="/etc/ip6rtrd.conf"
ND6HOSTD="no"
ND6HOSTD_FLAGS=""
```

3.6.11 Editing the Router Configuration File

After you configure the system as an IPv6 router, the `ip6rtrd` daemon sends out periodic router advertisements for the following reasons:

- Advertise itself as a potential default router for IPv6 traffic. The IPv6 nodes on the link receive these advertisements as part of their Neighbor Discovery processing.
- Advertise an IPv6 address prefix, in which case IPv6 nodes on the link perform address autoconfiguration.

The `/etc/ip6rtrd.conf` file contains the configuration data needed to send Router Advertisement messages. This file is created when `ip6_setup` is run, if the system is configured as a router. The link interface and advertised prefix are inserted, and other default values are used. You can

modify this file as appropriate for your network, for example, when using multiple prefix values. See `ip6rtrd.conf(4)` for more information.

Example 3–3 is a sample configuration file.

Example 3–3: Sample `ip6rtrd.conf` File

```
#
# Sample ip6rtrd configuration file
#
interface tu0 {
    MaxRtrAdvInterval 600
    MinRtrAdvInterval 200
    AdvManagedFlag 0
    AdvOtherConfigFlag 0
    AdvLinkMTU 1500
    AdvReachableTime 0
    AdvRetransTimer 0
    AdvCurHopLimit 64
    AdvDefaultLifetime 1800
    Prefix dec:1::/64 {
        AdvValidLifetime 1200
        AdvPreferredLifetime 600
        AdvOnLinkFlag 1
        AdvAutonomousFlag 1
    }
}
```

3.6.12 Tuning the Kernel Subsystems

You can use either the `sysconfig` utility or `dxkerneltuner` to tune the IPv6 subsystems. See `sys_attrs_ipv6(5)` and `sys_attrs_ip tunnel(5)` for information on tuning the IPv6 subsystem and IP tunnel subsystem, respectively.

3.7 IPv6 Daemon Log Files

The `nd6hostd` and `ip6rtrd` daemons log informational and severe events in the `/var/adm/syslog.dated/date/daemon.log` file. You can view the contents of this message file by using the Event Viewer that is part of the SysMan Menu utility. See Section 16.10 for more information about the Event Viewer.

By default, the daemons do not log debug information. To enable logging of debug information for the `nd6hostd` daemon, issue the following commands:

```
# rcmgr set ND6HOSTD_FLAGS "-d -l /usr/tmp/nd6hostd.log"
# /usr/sbin/rcinet restart ipv6
```

To enable logging of debug information for the `ip6rtrd` daemon, issue the following commands:

```
# rcmgr set IP6RTRD_FLAGS "-d -l /usr/tmp/ip6rtrd.log"  
# /usr/sbin/rcinet restart ipv6
```

Asynchronous Transfer Mode

Asynchronous Transfer Mode (ATM) networks provide the following capabilities:

- Speeds from 25 M/bps to 622 M/bps or greater through cell-switching.
- Multiple qualities of service.
- Connection-oriented interconnection with resource reservation for individual connections. These connections might be for conversations between two applications or for a connection over which many conversations between many applications and protocols are multiplexed.

ATM networks provide the high speed and the low latency (switched, full duplex network infrastructure) that applications, particularly those running on local area networks, require.

This chapter describes:

- The ATM network environment
- How to configure the ATM subsystem
- How to manage the ATM subsystem

See the *Asynchronous Transfer Mode* guide for information about writing device drivers and kernel modules for ATM. For troubleshooting information, see Section 15.5.

4.1 ATM Environment

An ATM network consists of the following:

- Switch

A specialized system that maintains a list of virtual channel identifiers (VCIs) and virtual path identifiers (VPIs), connects one end system to another, and forwards or switches ATM cells from one end system to another based on the VCI/VPI information contained in the cell.

- End system

A system physically connected to a switch that communicates with other end systems through the switch.

In the operating system's ATM environment, the following configurations are possible:

- Classical Internet Protocol (CLIP)
- Local Area Network (LAN) emulation
- IP switching

The following sections describe each of these configurations and the roles of systems in each.

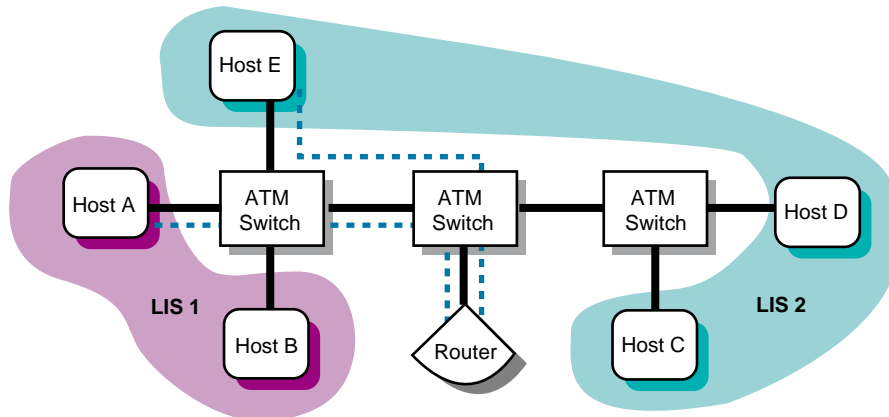

4.1.1 Classical IP Environment

The Classical IP environment, as described in RFC 1577, provides a basic means for carrying unicast IP traffic over ATM networks. In this environment, hosts that can communicate with each other are grouped into a Logical IP Subnetwork (LIS). An ATM network can contain multiple LISs. In a LIS, all hosts and routers have the following requirements:

- Have the same IP network/subnetwork number and mask.
- Are directly connected to the ATM network.
- Access members outside the LIS through a router.
- For switched virtual circuits (SVCs), use Address Resolution Protocol (ARP) to resolve IP protocol addresses to ATM hardware addresses. For SVCs and permanent virtual circuits (PVCs), use Inverse ARP to resolve ATM hardware addresses to IP protocol addresses.
- Can communicate with all other members in the same LIS (mesh topology).

Figure 4–1 shows an ATM network with two LISs. Host A and Host B are members of LIS 1; Host C, Host D, and Host E are members of LIS 2. The figure also shows a virtual circuit (VC) between Host A and the router and between Host E and the router. Although these hosts are connected to the same switch and might establish a VC for communications between each other, they cannot because all communications to a member of another LIS must go through a router.

Figure 4–1: Classical IP over an ATM Network

ZK-1307U-AI

4.1.2 LAN Emulation Environment

The LAN Emulation (LANE) environment, as defined by the ATM Forum, groups hosts into an entity called an emulated LAN (ELAN). A LANE environment has the following characteristics:

- Identifies hosts through their 48-bit media access control (MAC) addresses
- Supports multicast and broadcast services either through point-to-multipoint connections or through a multicast server, unlike the Classical IP environment
- Supports any protocol that uses an IEEE broadcast LAN

In addition, LANE interfaces (`e1an`) are supported by NetRAIN. See `nr(7)` for more information.

Figure 4–2 shows an ATM network with two emulated LANs. Host A and Host B are LAN Emulation Clients (LECs) on ELAN 1. Host C, Host D, and Host E are LECs on ELAN 2. The LECS (LAN Emulation Configuration Server), the LES (LAN Emulation Server), and the BUS (Broadcast and Utility Server) are depicted as two separate systems, although these server functions are typically resident on an ATM switch.

Figure 4–2: Emulated LAN over an ATM Network

4.1.3 IP Switching

Note

IP switching support is provided for backward compatibility only; it will be retired in a future release. Do not use it to develop new applications.

The IP switching environment consists of one or more hosts connected to an IP switch. Each host is connected to the IP switch through a point-to-point physical connection, with each physical connection as a separate subnet. Communication between the host and the IP switch occurs over dynamically created PVCs.

The IP switch is a typical ATM switch with added IP controller software that performs IP routing and IP traffic classification functions. In this environment, a series of packets moving from one host to another with the same protocol type, type of service, and other characteristics indicated in the packet header is called a **flow**. When the IP controller identifies a flow that is of long duration, it instructs the ATM switch to make the appropriate hardware connections and to forward the ATM cells directly to the destination, bypassing the IP controller. This increases throughput at the switch and throughout the network.

The operating system's IP switching implementation is based on the Ipsilon Networks, Inc. reference model and has the following characteristics:

- Supports IP traffic only

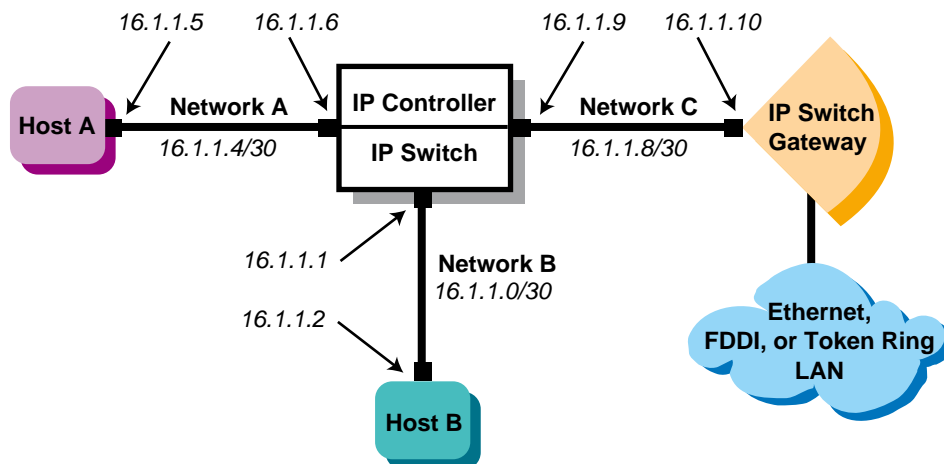

- Supports multicast and broadcast services
- Does not require systems to function as ARP servers or multicast servers
- Uses the Ipsilon Flow Management Protocol (IFMP) to exchange control information with the IP switch
- Does not require that ATM Forum signaling (options UNI3X) be configured on the system
- Requires fewer configuration steps than Classical IP and LAN emulation

IP switching over ATM has the following restrictions:

- Only one IP switching interface (`ips`) per host is supported.
- If using a driver for IP switching, you may not use other ATM protocols on that driver.
- The `tcpdump` and `packetfilter` utilities are not supported on an `ips` interface.

Figure 4–3 shows a simple ATM network with an IP switch, IP switch gateway, some hosts, and a legacy LAN network. Host A (16.1.1.5), Host B (16.1.1.2), and the IP switch gateway (16.1.1.10) are on separate subnets (16.1.1.4/30, 16.1.1.0/30, and 16.1.1.8/30). The IP switch gateway runs a routing protocol and advertises routes to other subnets to hosts on the legacy LAN.

Figure 4–3: IP Switching over an ATM Network

ZK-1305U-AI

For the IP switching subnetworks, the recommended network mask length is 30 bits. This allows for two bits for each host address, one bit for the subnetwork address, and one bit for the broadcast address. Using large

netmasks helps to conserve IP address space on subnetworks that have a few hosts attached.

4.2 Planning ATM

This section describes the tasks you need to complete before configuring the ATM software.

4.2.1 Verifying That the ATM Subsets Are Installed

Verify that the ATM subsets are installed by entering the following command:

```
# setld -i | grep ATM
```

If all of the subsets are not installed, install them by using the `setld` command. For more information on installing subsets, see `setld(8)`, the *Installation Guide*, or the *System Administration* manual.

Note

You do not have to install the `OSFATMBINOBJECT` subset.

4.2.2 Configuring ATM into the Kernel

After you install the ATM subsets, verify that the ATM support you require is in the kernel by issuing the following command:

```
# sysconfig -q atm
```

If `atm:` is not displayed, log in as superuser and complete the following steps:

1. Build a new kernel by issuing the `doconfig` command. If you are unfamiliar with rebuilding the kernel, see the *System Administration* manual.
2. When prompted, select one or more of the kernel options described in Table 4-1.

Note

If the ATM hardware is already installed, `options ATM` is automatically selected as a mandatory option.

3. Reboot your system with the new kernel by issuing the following command:

```
# shutdown -r now
```

This command immediately shuts down and automatically reboots the system.

Table 4–1: ATM Kernel Options

Option	Purpose
<code>options ATM</code>	For base ATM support (required)
<code>options UNI3X</code>	For ATM Forum signaling with either LANE or Classical IP
<code>options ATMILMI3X</code>	For ATM Forum Integrated Layer Management Interface (ILMI) support
<code>options ATMIP</code>	For Classical IP services
<code>options LANE</code>	For ATM Forum LAN Emulation (LANE)
<code>options ATMIFMP</code>	For IP switching

4.2.3 Preparing for the Configuration

After verifying that ATM support is in the kernel, you can configure ATM. To configure ATM, you need to configure an ATM adapter and one or more of the following interfaces:

- A Classical IP logical interface
- A LAN Emulation logical interface
- An IP switching logical interface

The type of information you need depends on the environment you want to set up and use.

4.2.3.1 Adapter Information

Figure 4–4 shows the ATM Setup Worksheet. The following sections explain the information you need to record on this worksheet. If you are viewing this manual on line, you can use the print feature to print a copy of the worksheet.

Figure 4–4: ATM Setup Worksheet

ATM Setup Worksheet	
Adapter name:	_____
ROM ESIs:	_____
More ESIs:	_____
Network layer:	SONET <input type="checkbox"/> SDH <input type="checkbox"/>
Flow control:	Yes <input type="checkbox"/> No <input type="checkbox"/>
ILMI:	Yes <input type="checkbox"/> No <input type="checkbox"/>
Signaling:	Yes <input type="checkbox"/> No <input type="checkbox"/>
VC accounting:	Yes <input type="checkbox"/> No <input type="checkbox"/>
UNI version:	3.0 <input type="checkbox"/> 3.1 <input type="checkbox"/>

Adapter name

The device names of the ATM network interfaces. For example, the `lta` network interface.

ROM ESIs

The ROM end system identifier (ESI) addresses of the adapter that you want to register with the system and the local switch. If you want to register all of the adapter's ROM ESI addresses, leave this blank.

Depending on the number of address prefixes assigned by the switch, you can create one or more ATM addresses. The driver can control up to 64 ROM ESI addresses, though adapters generally have only a few ROM ESI addresses.

More ESIs

Additional ESI addresses that you want to register with the system and the local switch. An ESI address has twelve hexadecimal digits.

Network layer

If you want to enable Synchronous Optical Network (SONET), on the adapter, check SONET. If you want to enable Synchronous Digital Hierarchy (SDH) mode on an ATM adapter that supports both SONET and SDH physical interfaces, check SDH.

Flow control

If you want to enable vendor-specific flow control on the adapter, check Yes; otherwise, check No. The adapter must support this type of flow control. Compaq adapters and switches support FLOWmaster vendor flow control.

ILMI

If you want to enable the Integrated Layer Management Interface (ILMI) on the adapter, check Yes; otherwise, check No. You must enable ILMI when using Classical IP over switched virtual circuits (SVCs).

Signaling

If you want to enable signaling on the adapter, check Yes; otherwise, check No. You must enable signaling when using Classical IP over SVCs.

VC accounting (signaling only)

If you want to enable logging of virtual circuit (VC) releases, check Yes; otherwise, check No.

UNI version (signaling only)

The signaling version to use on the adapter. If you want to use User-Network Interface (UNI) Version 3.0, check 3.0. If you want to use UNI Version 3.1, check 3.1. The default is 3.0.

4.2.3.2 Classical IP Information

Figure 4-5 shows the ATM Classical IP Worksheet. The following sections explain the information you need to record on this worksheet. If you are viewing this manual on line, you can use the print feature to print a copy of the worksheet.

ATM address (ARP client only)

The ATM address of the ATM ARP server, either a host name or alias that appears in the `/etc/atmhosts` file or a 40-digit ATM End System Address (AESA) with selector byte. The ARP server must also be on the ATM network.

Note

The ATM Forum now calls an NSAP-style address an AESA.

IP address (ARP client only)

The IP address of the ATM ARP server machine.

VCI (PVCs only)

The virtual channel identifier (VCI) for the PVC.

VPI (PVCs only)

The virtual path identifier (VPI) for the PVC.

Remote Classical IP (PVCs only)

If the remote host supports Classical IP as defined in RFC 1577, check Yes; otherwise, check No.

Remote IP address (PVCs only)

If the remote host does not support Classical IP, enter the remote host's IP address.

4.2.3.3 LAN Emulation Information

Figure 4-6 shows the ATM LAN Emulation Worksheet. The following sections explain the information you need to record on this worksheet. If you are viewing this manual on line, you can use the print feature to print a copy of the worksheet.

Figure 4–6: ATM LAN Emulation Worksheet

ATM LAN Emulation Worksheet			
ATM hosts file	ATM address:	Host name:	Alias:
	_____	_____	_____
	_____	_____	_____
	_____	_____	_____
	_____	_____	_____
	_____	_____	_____
	_____	_____	_____
	_____	_____	_____
	_____	_____	_____

LANE
ELAN number: _____
ELAN name: _____
Mode: Default LECS Specific LECS LES
LECS name: _____
LES name: _____
MTU size: 1516 4544 9234 18190

ATM address

The ATM addresses of the LAN Emulation Servers (LES) on your ATM network to add to the `/etc/atmhosts` file.

Host name

The names of the LES on the ATM network to be added to the `/etc/atmhosts` file.

Alias

The aliases, if any, of the LES to be added to the `/etc/atmhosts` file.

ELAN number

A LAN Emulation Client (LEC) interface unit number.

ELAN name

The name of the emulated LAN to join; this is optional. The emulated LAN name must already be configured on the ATM switch. If the name is not configured on the ATM switch, the LEC joins the default emulated LAN.

Mode

If you want to contact the default LAN Emulation Configuration Server (LECS), check Default LECS. The LEC contacts the LECS by using an ILMI MIB request to obtain the LECS address. If the request is unsuccessful, the LEC uses the well-known address for the LECS. If you want to contact a specific LECS, check Specific LECS. In either case, the LEC contacts a LECS to obtain a LES address.

If you want to contact the LAN Emulation Server (LES) directly, check LES.

LECS name

The ATM address of the LECS, either a host name or alias that appears in the `/etc/atmhosts` file or a 40-digit ATM AESA address with selector byte. If you want to contact a specific LECS, enter the LECS address; you can specify up to four.

LES name

The ATM address of the LES, either a host name or alias that appears in the `/etc/atmhosts` file or a 40-digit ATM AESA address with selector byte. If you want the LEC to go directly to the LES and bypass the configuration phase, enter the LES address.

MTU size

The maximum transmission unit (MTU) size. The following MTU sizes are supported: 1516, 4544, 9234, and 18190. When specified with a virtual LAN name, the emulated LAN must already be configured on the ATM switch to support the specified MTU size. If it is not configured for the specified MTU size, the request is ignored.

4.2.3.4 IP Switching Information

Figure 4-7 shows the ATM IP Switching Worksheet. The following sections explain the information you need to record on this worksheet. If you are viewing this manual on line, you can use the print feature to print a copy of the worksheet.

ips number

The IP switching (`ips`) interface number. If you are using multiple adapters, each adapter is assigned a separate interface number.

SNAP VCI

The Virtual Channel Identifier (VCI) number that Ipsilon Flow Management Protocol (IFMP) uses as the default Subnetwork Attachment Point (SNAP) VCI. The default VCI is 15. This number must match the VCI number that IFMP uses on the destination host or switch associated with the point-to-point interface.

Routing

The method you use to update your internal routing tables. If you use the `gated` daemon, check `gated`. If you use the `routed` daemon, check `routed`. If you use static routes, check `static routes`.

Destination (static routes only)

The IP address of the destination subnetwork.

Gateway (static routes only)

The IP address of the IP controller on the IP switch.

Netmask (static routes only)

The netmask for the destination subnetwork.

4.3 Configuring ATM

After you complete the required ATM planning and you install the appropriate ATM hardware, you can configure the ATM software. Use the ATM Configuration application of the Common Desktop Environment (CDE) Application Manager to configure ATM. You can configure the following:

- ATM adapter
- Classical IP
- LAN Emulation
- IP Switching

To use the ATM Configuration application, invoke the SysMan Menu application as specified in Section 1.1.1, then see Section 4.3.1 for further instructions.

Optionally, you can use the `atmsetup` script that was available in previous releases by executing the `atmsetup -old` command. See the online help and `atmsetup(8)` for more information.

4.3.1 Configuring an ATM Adapter

Before you can configure ATM logical interfaces, you must configure an adapter. To configure an ATM adapter, do the following:

1. From the SysMan Menu, select Networking→Basic Network Services→Set up Asynchronous Transfer Mode (ATM) to display the ATM Configuration main window.

Alternatively, enter the following command on a command line:

```
# /usr/sbin/sysman atm
```

Or, enter:

```
# atmsetup
```

The ATM Configuration main window displays the unconfigured adapters, configured adapters, and configured logical interfaces.

2. Select an adapter from the Unconfigured Adapters field.
3. Select Configure. The Configure/Modify Adapter dialog box is displayed.
4. If you do not want to register all ROM Endpoint System Identifiers (ESIs) for the adapter, select Register ROM ESI. By default, all of the adapter's ROM ESI addresses are registered.
5. If you want to register additional ESIs (called soft ESIs) for the adapter, select Register Soft ESI.
6. If you want to set transmit Constant Bit Rate (CBR) or pacing options for the adapter, select Set CBR/Pacing Options. The Set CBR/Pacing Options dialog box is displayed. When you are finished, select OK to close the dialog box and save the changes.
7. Indicate the type of network physical layer you want the adapter to support: SONET or SDH.
8. Indicate whether you want to enable flow control (FLOWmaster) on the adapter.
9. Indicate whether you want to enable Integrated Local Management Interface (ILMI) on the adapter.
10. Indicate whether you want to enable signaling on the adapter.
11. Indicate whether you want to enable the logging of all virtual circuit (VC) releases.
12. Select a User-Network Interface (UNI) version.

13. Select OK to accept the configuration and close the Configure/Modify Adapter dialog box. You can now configure an ATM logical interface.

You can also modify your adapter configuration. See the online help and `atmsetup(8)` for more information.

4.3.2 Configuring Classical IP

Before you configure Classical IP, you must configure an ATM adapter. Configuring Classical IP on your host consists of the following steps:

1. Creating PVC mappings on your ATM switch (PVCs only).
2. Adding servers the `atmhosts` file.
3. Adding hosts to the `hosts` database.
4. Running the ATM Configuration application.
5. Configuring the Classical IP logical interface.
6. Adding static routes (SVCs only).
7. Verifying the PVC Configuration (PVCs only).

The following sections describe these steps.

4.3.2.1 Creating PVC Mappings on Your ATM Switch

If you are going to use PVCs and your environment requires an ATM switch, you need to create PVC mappings on the switch. The method for creating these mappings depends on the type of ATM switch you use. See your ATM switch documentation for more information.

4.3.2.2 Adding Servers to the `atmhosts` File

You edit the `/etc/atmhosts` file to add the address of the ATM ARP server on your ATM network. The `/etc/atmhosts` file contains mappings of ATM host names to ATM hardware addresses. This file can also contain ATM ESIs and AESAs for specific services on the ATM network. Putting entries in this file enables you to specify the address or service by name instead of specifying a long hexadecimal string.

Entries in the `/etc/atmhosts` file can be one of the following:

- A comment, denoted by a pound sign (#) as the first character
- An address specification

The address specification is similar to that of IP addresses in the `/etc/hosts` file, and has the following format:

```
atm_addr hostname [ alias ... ]
```

The `atm_addr` parameter can consist of ESIs or AESAs.

The following table lists the address type and the number of hexadecimal address digits required for each type:

Address Type	Number of Address Digits
ESI	Twelve hexadecimal digits
AESA	Thirty-eight hexadecimal digits
AESA with selector byte	Forty hexadecimal digits

The `hostname` parameter can contain any printable character.

The following example shows entries in the `/etc/atmhosts` file:

```
08002b2fe740 myhost.esi 1
47840f01020300002122313208002b2fe740 myhost 2
47840f01020300002122313208002b2fe7403a myhost.ip 3
```

- 1 Specifies an ESI to use in registering `myhost` with the switch.
- 2 Specifies the AESA of `myhost`. This is the network prefix and the ESI, and is the address that the network recognizes.
- 3 Specifies the AESA with selector byte of a service on `myhost` for the operating system's implementation of RFC 1577, *Classical IP and ARP over ATM*.

Note

By default, the `atmhosts` file contains an entry for PVCs. Do not delete or modify this entry.

4.3.2.3 Adding Hosts to the hosts Database

You add the IP addresses for all ATM hosts that will be on any Logical IP Subnet (LIS) to which the host will connect to the `hosts` database. Make sure you have the IP addresses for the local host and the ATM ARP server. Depending on your environment, host names and addresses can be in the local `/etc/hosts` file or in one of the files distributed with DNS or NIS.

You can enter these IP addresses in the `/etc/hosts` file either by editing the file itself or by running the SysMan Menu application of the CDE Application Manager. See Section 2.3.7 for more information.

4.3.2.4 Running the ATM Configuration Application

To configure Classical IP on your system, do the following:

1. From the SysMan Menu, select Networking→Basic Network Services→Set up Asynchronous Transfer Mode (ATM) to display the ATM Configuration main window.

Alternatively, enter the following command on a command line:

```
# /usr/sbin/sysman atm
```

Or, enter:

```
# atmsetup
```

The ATM Configuration main window displays the unconfigured adapters, configured adapters, and configured logical interfaces.

2. Select Add. The Add Interfaces dialog box is displayed.
3. Select Classical IP. The Add Interfaces dialog box closes. The Add/Modify Classical IP Interface dialog box is displayed.
4. Choose the adapter on which you want to add a Classical IP logical interface.
5. If you do not want to use the default logical interface number, enter a different number.
6. Indicate whether your system is to act as an ARP client or an ARP server.
7. If the system is to be an ARP client, enter the ARP server's ATM address or alias. Then, enter the ARP server's IP address.
8. If you are going to specify PVCs for the logical interface, select PVCs. The Add/Modify PVC dialog box is displayed. Do the following:
 - a. Enter a virtual path identifier (VPI) for the virtual circuit.
 - b. Enter a virtual channel identifier (VCI) for the virtual circuit.
 - c. Indicate whether the remote host entity supports Classical IP as defined in RFC 1577.
 - d. If the remote host does not support Classical IP, enter the remote host's IP address.
 - e. Select OK to accept the configuration and close the Add/Modify PVC dialog box.
9. Select OK to close the Add/Modify Classical IP Interface dialog box.
10. Select OK in the ATM Configuration main window to save the changes. If no ATM interface exists on the system, the Start ATM Now dialog box is displayed. If you want to start ATM the ATM subsystem, select OK;

otherwise, select No. If you select No, you must reboot the system to start the ATM subsystem.

If an ATM interface exists on the system, the Reboot Required dialog box is displayed. Select OK to acknowledge the message. You must reboot the system to start the ATM subsystem.

You can also modify your adapter configuration. See the online help and `atmsetup(8)` for more information.

4.3.2.5 Configuring the Classical IP Logical Interface

After you run the ATM Configuration application and start the ATM components (either from within the application or by rebooting the system), you can configure the Classical IP (`lis`) interface. To configure the `lis` interface, see Section 2.3.1.

4.3.2.6 Adding Static Routes (SVC only)

Depending on your network topology and the number and configuration of logical IP subnetworks (LISs) in your network, you might need to add static routes to other hosts if you want a connection to a host that is on another LIS subnet. To add a static route to the routing tables, see Section 2.3.6.

4.3.2.7 Verifying the PVC Configuration (PVCs only)

After the PVC is configured, verify the configuration by issuing the `atmarp -a` command. Output similar to the following appears if the PVC is configured:

```
# atmarp -a
Number of entries : 1

IP Address :   atm66 (16.142.128.66)
ATM Address : PVC
Flags :       Complete Permanent
VCs :        vpi   vci   VC Type
              ---   ---   -
              0     999   PVC
```

4.3.3 Configuring LAN Emulation

Configuring LAN emulation on your host consists of the following steps:

1. Adding servers to the `atmhosts` file.
2. Adding hosts to the `hosts` database.
3. Running the ATM Configuration application.

4. Configuring the LAN Emulation logical interface.s

The following sections describe these steps.

4.3.3.1 Adding Servers to the atmhosts File

You edit the `/etc/atmhosts` file only if you want to specify a LAN Emulation Server (LES) address or LAN Emulation Configuration Server (LECS) addresses on your ATM network. The `/etc/atmhosts` file contains mappings of ATM host names to ATM hardware addresses. This file can also contain ATM ESIs and AESAs for specific services on the ATM network.

See Section 4.3.2.2 for more information on editing the `/etc/atmhosts` file.

4.3.3.2 Adding Hosts to the hosts Database

You add the IP addresses for all ATM hosts that will be on any emulated LAN (ELAN) to which the host will connect to the `hosts` database. Make sure you have the IP addresses for the local host. Depending on your environment, host names and addresses can be in the local `/etc/hosts` file or in one of the files distributed with DNS or NIS.

You can enter these IP addresses in the `/etc/hosts` file either by editing the file itself or by running the SysMan Menu application of the CDE Application Manager. See Section 2.3.7 for more information.

4.3.3.3 Running the ATM Configuration Application

To configure LAN emulation on your system, do the following:

1. From the SysMan Menu, select Networking→Basic Network Services→Set up Asynchronous Transfer Mode (ATM) to display the ATM Configuration main window.

Alternatively, enter the following command on a command line:

```
# /usr/sbin/sysman atm
```

Or, enter:

```
# atmsetup
```

The ATM Configuration main window displays the unconfigured adapters, configured adapters, and configured logical interfaces.

2. Select Add. The Add Interfaces dialog box is displayed.
3. Select LAN Emulation. The Add Interfaces dialog box closes. The Add/Modify LAN Emulation Interface dialog box is displayed.
4. Choose the adapter on which you want to add a LAN Emulation logical interface.

5. If you do not want to use the default logical interface number, enter a different number.
6. If you want to join a specific emulated LAN, enter the name of the emulated LAN you want to join.
7. Choose the mode by which your system will be registered into the emulated LAN. If you choose to contact a specific LAN Emulation Configuration Server (LECS) (the second choice), also enter the LECS name or alias. If you choose to contact a LAN Emulation Server (LES) directly (the third choice), also enter the LES name or alias.
8. If you want to specify an MTU size other than the default 1516, choose another MTU size.
9. Select OK to close the Add/Modify LAN Emulation Interface dialog box.
10. Select OK in the ATM Configuration main window to save the changes. If no ATM interface exists on the system, the Start ATM Now dialog box is displayed. If you want to start ATM the ATM subsystem, select OK; otherwise, select No. If you select No, you must reboot the system to start the ATM subsystem.

If an ATM interface exists on the system, the Reboot Required dialog box is displayed. Select OK to acknowledge the message. You must reboot the system to start the ATM subsystem.

Note

You can join an ELAN on an ATM switch only once for each adapter; do not join the same ELAN multiple times from the same adapter. If you want to join the same ELAN on the same switch, you must install another adapter and join the ELAN from it.

You can also modify your adapter configuration. See the online help and `atmsetup(8)` for more information.

4.3.3.4 Configuring the LAN Emulation Logical Interfaces

After you run ATM Configuration and start the ATM components (either from within the application or by rebooting the system), you configure the LAN Emulation (`elan`) interface. To configure the `elan` interface, see Section 2.3.1.

4.3.4 Configuring IP Switching

Configuring IP switching on your host consists of the following steps:

1. Adding IP addresses to the `hosts` file

2. Running the ATM Configuration application to create the IP Switching logical interface
3. Configuring the IP Switching logical interface
4. Adding routes to the routing table

The following sections describe these steps.

4.3.4.1 Adding IP Addresses to the hosts File

You edit the `/etc/hosts` file to add the IP addresses for each IP switching subnetwork to which the host will connect. For each subnet, add a pair of IP addresses for each end of the point-to-point link (host side and IP controller side), the IP address of the subnet, and the broadcast address of the subnet. For example, an `/etc/hosts` file for the configuration in Figure 4–3 is as follows:

```
# IP Switching subnet A
16.1.1.4  networka-net
16.1.1.5  hosta.corp.com          hosta          atm5
16.1.1.6  ipsctrlhosta.corp.com ipsctrlhosta  atm6
16.1.1.7  networka-broadcast
# IP Switching subnet B
16.1.1.0  networkb-net
16.1.1.1  ipsctrlhostb.corp.com ipsctrlhostb  atm1
16.1.1.2  hostb.corp.com       hostb          atm2
16.1.1.3  networkb-broadcast
# IP Switching subnet C
16.1.1.8  networkc-net
16.1.1.9  ipsctrlhostc.corp.com ipsctrlhostc  atm9
16.1.1.10 ipgwy.corp.com            ipgwy         atm10
16.1.1.11 networkc-broadcast
```

You can enter these IP addresses in the `/etc/hosts` file either by editing the file itself or by running the SysMan Menu application of the CDE Application Manager. See Section 2.3.7 for more information.

4.3.4.2 Running the ATM Configuration Application

Do the following to configure IP switching on your system:

1. From the SysMan Menu, select **Networking**→**Basic Network Services**→**Set up Asynchronous Transfer Mode (ATM)** to display the ATM Configuration main window.

Alternatively, enter the following command on a command line:

```
# /usr/sbin/sysman atm
```

Or, enter:

```
# atmsetup
```

The ATM Configuration main window displays the unconfigured adapters, configured adapters, and configured logical interfaces.

2. Select Add. The Add Interfaces dialog box is displayed.
3. Select IP Switching. The Add Interfaces dialog box closes. The Add/Modify IP Switching Interface dialog box is displayed.
4. Choose the adapter on which you want to add an IP Switching logical interface.
5. If you do not want to use the default logical interface number, enter a different number.
6. If you want to change the virtual channel identifier (VCI) information from the default, select Options. The Modify IP Switching Options dialog box is displayed. Do the following:
 - a. Enter a SNAP VCI value, if other than 15 (the default).

Note

This SNAP VCI number must match the VCI number that IFMP uses on the switch associated with the point-to-point interface.

- b. Enter a range of VCIs to use for transmitting and receiving connections.
 - c. Select OK to save the changes and close the Modify IP Switching Options dialog box.
7. Select OK to close the Add/Modify IP Switching Interface dialog box.
8. Select OK in the ATM Configuration main window to save the changes. If no ATM interface exists on the system, the Start ATM Now dialog box is displayed. If you want to start ATM the ATM subsystem, select OK; otherwise, select No. If you select No, you must reboot the system to start the ATM subsystem.

If an ATM interface already exists on the system, the Reboot Required dialog box is displayed. Select OK to acknowledge the message. You must reboot the system to start the ATM subsystem.

You can also modify your adapter configuration. See the online help and `atmsetup(8)` for more information.

4.3.4.3 Configuring the IP Switching Logical Interfaces

After you run ATM Configuration and start the ATM components (either from within the application or by rebooting the system), you configure the IP Switching (`ips`) interface. To configure the `ips` interface, see Section 2.3.1.

4.3.4.4 Adding Routes

Depending on your network topology and the number of interfaces on your host, you might need to add routes to other hosts if your system has multiple interfaces and the default route is to another gateway on another network. Do either of the following:

- Run either `gated` or `routed` to automatically update your system's routing tables.
- Add a static route to the routing tables for the destination network. Select Networking→Configuration→Static Routes from the SysMan Menu. This opens the Static Routes File dialog box. You need to specify the IP address of the destination subnetwork and address of the IP controller on the IP switch. For example, if you were configuring IP switching on Host A in Figure 4–3 and you wanted to route all traffic on all 16.1.1 networks through the IP switch, you would specify 16.1.1/24 as the destination address in Classless Inter-Domain Routing (CIDR) format and 16.1.1.6 as the gateway address.

Add entries for each additional network with which your system needs to communicate. See Section 2.3.6 for more information.

4.4 Managing the ATM Environment

Managing the ATM environment consists of managing the following components:

- ATM networking and displaying information about ATM networks
- The signaling module
- The Classical IP environment
- The LAN Emulation environment
- IP switching
- ATM subsystem messages

The following sections describe how to manage these components.

4.4.1 ATM Networking and Displaying Information About ATM Networks

To manage ATM networking and to display information about the ATM networks, you use the `atmconfig` command. The command controls only the base ATM modules and device drivers; it does not control specific convergence modules or signaling protocols. You can use the `atmconfig` command to do the following:

- Enable and disable device drivers
- Create and destroy PVCs
- Destroy SVCs
- Create and destroy ESIs
- Display the currently active VCs and driver status
- Process configuration batch files

See `atmconfig(8)` for more information.

4.4.2 The Signaling Module

To manage ATM UNI signaling on the end system, you use the `atmsig` command. The `atmsig` command allows you to:

- Display state information about the signaling module
- Disable and enable the ILMI and signaling
- Read and modify the various timer values and statistics for Q.SAAL and Q.93B (2931)

The signaling module is associated with a specified interface at all times, which is identified by the driver name. If the interface is disabled, the signaling module is also disabled. The signaling module must be enabled again when the interface is brought back on line.

See `atmsig(8)` for more information.

4.4.3 The Classical IP Environment

To manage Classical IP on an end system, you use the `atmarp` command. The `atmarp` command allows you to:

- Create a logical IP subnet (LIS) interface
- Create and delete entries in the ATM ARP table
- Display entries in the ATM ARP table
- Toggle the permanent flag for entries

- Display the local host's ATM configuration status
- Create and remove an association between an established VC and a remote IP entity that does not support Classical IP

See `atmarp(8)` for more information.

4.4.4 The LAN Emulation Environment

Managing the LAN emulation environment consists of the following tasks:

- Managing LAN Emulation Clients (LECs)
- Displaying the LAN Emulation Address Resolution Protocol (LE-ARP) table

The following sections describe these tasks.

4.4.4.1 Managing LAN Emulation Clients

To manage LAN Emulation Clients (LECs), you use the `atmelan` command. The `atmelan` command allows you to:

- Create and configure LAN Emulation Clients (LEC) as network interfaces
- Display counters, parameters, and the state of each LEC

See `atmelan(8)` for more information.

4.4.4.2 Displaying the LE-ARP Table

To display the LE-ARP table for each `elan` interface, you use the `learp` command. The command displays the address mappings for the emulated LAN. Each entry consists of the Media Access Control (MAC) address, state, ATM address, and flags. See `learp(8)` for more information.

4.4.5 IP Switching

To manage IP switching on an end system, you use the `atmifmp` command. The `atmifmp` command allows you to:

- Enable and disable IP switching
- Display IP switching configuration
- Display or clear IP switching statistics
- Display IP switching flow information

See `atmifmp(8)` for more information.

4.4.6 ATM Subsystem Messages

The ATM subsystem logs status and error messages in the `/var/adm/syslog.dated/date/kern.log` file. You can view the contents of this message file by using the Event Viewer that is part of the SysMan Menu utility. See Section 16.10 for more information about the Event Viewer.

By default, the ATM subsystem logs subsystem initialization messages, important state changes, and significant error conditions. To increase the message level displayed by all ATM subsystem components, enter the following:

```
# sysconfig -r atm global_msg_level=2
```

You can also increase the message for individual subsystem components. For example, if you want to increase the message level for LANE to view session initialization information, enter the following:

```
# sysconfig -r lane lane_msg_level=2
```

See `sys_attrs_atm(5)` for more information.

Dynamic Host Configuration Protocol

Dynamic Host Configuration Protocol (DHCP) enables you to centralize and automate IP address administration. Using a graphical application, you can configure several computers at once, ensuring that configurations are consistent and accurate. Even portable computers can be automatically configured each time they attach to the network.

This chapter describes:

- The DHCP implementation on Tru64 UNIX systems
- How to configure a DHCP server by using the `xjoin` and SysMan Menu utilities
- How to configure a DHCP server to support BOOTP clients
- How to manage DHCP client addressing

The implementation of DHCP in Tru64 UNIX is based on JOIN[®] Server Version 4.1 from JOIN Systems, Inc. For additional information about DHCP, see the `DHCP(7)` reference page and the *JOIN Server Administrator's Guide*. The latter is provided by JOIN Systems in HTML format, and it can be accessed by opening the following file with a web browser:

```
/usr/doc/join/TOC.html
```

For troubleshooting information, see Section 15.6.

Note

Starting with Tru64 UNIX Version 4.0F, DHCP database files were stored in a new format that is incompatible with older formats. An online document explains the reasons behind this change, lists the files that are affected, and provides instructions for converting the files to the new format. The document, `README-DB237`, and conversion utility, `conv185-237`, are located in the `/etc/join` directory.

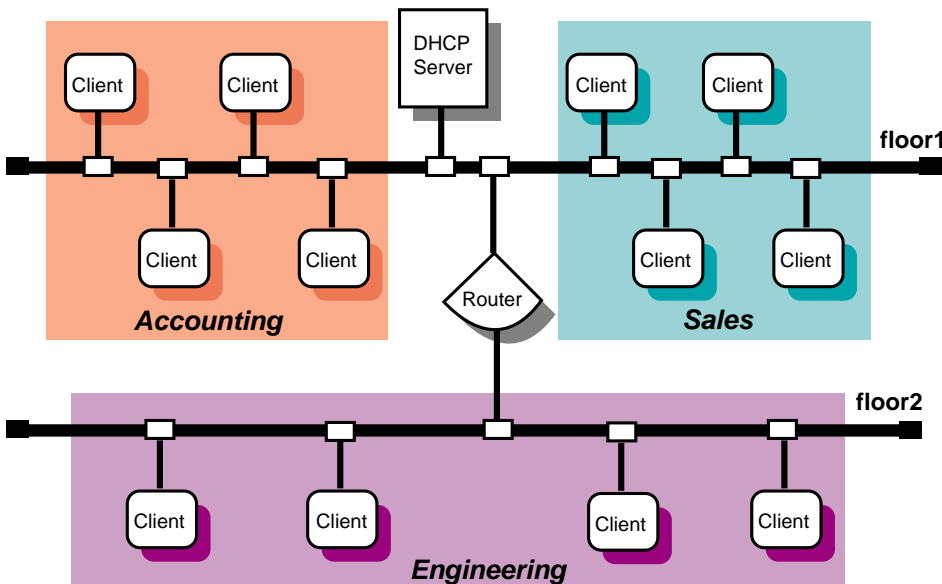

5.1 DHCP Environment

In the DHCP environment, systems can have the following roles:

- **Server** — A system that offers DHCP and BOOTP services to other systems on the network. Multiple servers can exist on a subnetwork, but each server's IP address range cannot overlap. If a cluster member is to support a DHCP server, there can be only one DHCP server for all of the cluster members using a common database with failover.
- **Client** — A system that requests configuration information from a DHCP server. A cluster member must never be a DHCP client. Use static addressing for cluster members.

Figure 5–1 shows a sample corporate LAN, named acme-net, in which a DHCP server is configured to supply IP addresses to clients in three different functional areas. In this configuration, the router must be configured to forward BOOTP packets. DHCP packets are BOOTP packets with DHCP extensions. See the `bprelay(8)` reference page for more information.

Figure 5–1: DHCP Configuration (acme-net)

ZK-1146U-AI

5.1.1 DHCP Parameter Assignment

In the DHCP environment, DHCP parameters can be assigned to the following named entities:

- **Groups** — Group parameters apply to all clients (nodes) on the network that share the same configuration values. By grouping these clients together, you can simplify the implementation and maintenance of your network configuration. You define a parameter once for a group instead of once for each individual node. After the group parameters are defined, you can use the settings for other subnetwork or node configurations. You can group nodes by logical area, by functional area, by physical area, or in any way you want. Groups can also be grouped together with other groups, subnetworks, and nodes.
- **Subnetworks** — Subnetwork parameters apply to all clients (nodes) on a subnetwork. A subnetwork can also be considered a group, but a group that also shares a common subnetwork address. Subnetworks can be grouped together with other subnetworks and nodes.
- **Nodes** — Node parameters apply to an individual client (node) in the network, and typically override subnetwork or group parameters.

These entities and their parameters have a hierarchical relationship to each other in your network. For example, Figure 5–1 shows a small business network named *acme-net*, comprising two subnetworks and three distinct groups, Accounting, Sales, and Engineering. A DHCP administrator might look at this network as one group named *acme-net*, consisting of two subnetworks, *floor1* and *floor2*, that contain the individual nodes.

The *acme-net* group, at the top level of the hierarchy, specifies those parameters that apply to all systems in the network. At the next level, the *floor1* subnetwork specifies those parameters that apply to all nodes on that subnetwork and the *floor2* subnetwork specifies those parameters that apply to all nodes on that subnetwork. If it were necessary to assign parameters on a group basis, the administrator could have the *floor1* subnetwork consist of the Accounting and Sales groups, with the individual nodes assigned to their respective groups. However, since these groups are on the same subnetwork, this is probably unnecessary.

If Figure 5–1 showed a single LAN with no subnetworks (no router), a DHCP administrator might look at this network as one group named *acme-net*, consisting of three groups (Accounting, Sales, and Engineering) that contain the individual nodes, respectively.

Groups can also be used to define a group of settings for one Ethernet or subnetwork number, allowing you to reuse the settings for other nodes or subnetwork configurations.

5.1.2 DHCP and Security

You can restrict client access to the DHCP server by creating a Media Access Control (MAC) address database. Only those clients with addresses in the

database are allowed to receive an IP address. See Section 5.8 for more information.

5.2 Planning DHCP

This section describes those tasks you need to do before configuring DHCP.

5.2.1 Verifying Installation of the DHCP Software

For a DHCP server system, verify that the DHCP server is installed by entering the following command:

```
# setld -i | grep OSFINET
```

If the subset is not installed, install it by using the `setld` command. For more information on installing subsets, see the `setld(8)` reference page, the *Installation Guide*, or the *System Administration* manual.

For DHCP client systems, the DHCP client software is installed with the mandatory subsets.

5.2.2 Preparing for the Configuration

After you verify that the DHCP software is installed, you can configure DHCP by using the `xjoin` utility to:

- Specify server parameters
- Specify basic DHCP parameters for groups, subnetworks, and nodes

The information you need depends on how you define the DHCP environment. The following sections contain worksheets that you can use to record the information required to configure DHCP.

5.2.2.1 Server/Security Parameters

Figure 5–2 shows the DHCP Server/Security Parameters Worksheet. If you are viewing this manual online, you can use the print feature to print this worksheet. The following sections explain the information you need to record on the worksheet.

Figure 5–2: DHCP Server/Security Parameters Worksheet

DHCP Server/Security Parameters Worksheet	
BOOTP address from pool:	True <input type="checkbox"/> False <input type="checkbox"/>
BOOTP compatibility:	True <input type="checkbox"/> False <input type="checkbox"/>
Default lease time:	_____
Name service:	/etc/hosts <input type="checkbox"/> DNS <input type="checkbox"/> NIS <input type="checkbox"/>
Ping timeout:	_____
Provisional time to live:	_____
Restrict to MAC address:	True <input type="checkbox"/> False <input type="checkbox"/>
IP ranges	
Subnetwork address:	_____
DHCP server:	_____
IP ranges:	_____

Host name lists	
Domain name:	_____
DHCP server:	_____
Host name prefix:	_____
Host names:	_____

BOOTP address from pool

If you want the DHCP server to allocate an address from the pool to BOOTP clients, check True. The address allocation is permanent. If you want the DHCP server to support BOOTP clients whose address is configured in the `/etc/bootptab` file (the usual method), check False; this is the default.

BOOTP compatibility

If you want the server to act as a BOOTP server in addition to a DHCP server when a client requests a BOOTP address, check True. For no BOOTP client support, check False. If you want to configure a BOOTP server only, see Section 5.10.

Default lease time

The default time (in days, hours, minutes, and seconds) of a client's DHCP lease, unless one is explicitly configured for the node, subnetwork, or group.

Name service

The name service to be used by the server. A name service must be configured for the DHCP server. The name service is used to authenticate, route, address, and perform naming-related functions for other systems on the network. The following types of name services can be used by the server:

- A Local Name Service updates the `/etc/hosts` file with information about dynamically assigned names and addresses.
- The Domain Name System (DNS) automatically translates host names to their numeric IP address.
- The Network Information Service (NIS) allows you to distribute host name information in a network.

Ping timeout

The time (in milliseconds) for the `ping` timeout. The `ping` command is used to determine if a client on your network is available. When the `ping` program sends a request to the client, the client responds to the request and includes its IP address in the response. The `Ping timeout` parameter is used to check that no other client is using an IP address prior to it being assigned by the server. After the timeout, the `ping` command stops checking.

Provisional time to live

The maximum time (in hours, minutes, and seconds) that an IP address remains on the provisionally allocated list before it can be allocated to another client. This prevents an IP address from being reused too quickly after a lease has expired.

Restrict to known MAC address

If you want to assign an IP address to a client's matching MAC address, check `True`; otherwise, check `False`. See Section 5.8 for additional information on restricting client access to the server.

IP ranges are those IP addresses available for assignment to clients on the network. Although multiple DHCP servers can reside on the same subnetwork, the IP address ranges administered by each server must not overlap. For IP ranges, supply the following information:

Subnetwork address

Subnetworks are logical subdivisions of a single TCP/IP network. The subnetwork IP number identifies one segment of the network. As the number of networks grows, routing IP addresses can get very

complicated. Using subnetworks allows more flexibility when assigning network addresses and simplifies the administration of network numbers. The IP address consists of the following information:

- Network address
- Subnetwork address
- Host address

The IP address is divided into four fields, each separated by a period. Each field represents an element of the address; for example, the following is a typical IP address:

```
128.174.139.47
```

In this example, 128.174 is the network address, 139 is the subnetwork address, and 47 is the host address; therefore, the full subnetwork address is 128.174.139.0.

DHCP server

The IP address of the DHCP server.

IP ranges

The group of unique IP addresses to be assigned to clients on the selected subnetwork. Using the previous subnetwork address as an example, if there are 25 clients on the subnetwork, the range of IP addresses is: 128.174.139.47 to 128.174.139.72.

A subnetwork address can have more than one corresponding IP Address Range.

The DHCP server can configure clients on more than one subnetwork as long as the routers between the server and the client forward BOOTP packets. See Section 5.2.2.2 and the `bprelay(8)` reference page for information about boot file and BOOTP parameters.

A host name list contains the names that are assigned clients when they are also assigned an IP address. For host name lists, supply the following information:

Domain name

A domain represents computers that are grouped together for administrative reasons. Domain names are usually assigned to a company, and make administering the domain easy. For example, if a domain is changed to have access to a new service on the network, each computer that is part of the domain automatically has access to the new service.

Write down the domain name exactly as it was assigned by the NIC Domain Registrar, and include its top-level domain extension; for example, `school.edu`, `company.com`, and `city.gov`.

DHCP server

The IP address of the DHCP server.

Host name prefix

A specific host name prefix that is assigned to a system when the system requests a host name and there are no host names available for assignment. For example, in the `company.com` domain, if the names in the Host name list box are all assigned and the host name prefix is `net12host`, the next computers to request host names will receive `net12host1`, `net12host2`, and so on as their host names.

Host names

The host names to be assigned to systems that request them.

5.2.2.2 Information for Basic DHCP Parameters

Figure 5–3 shows the Basic DHCP Parameters Worksheet. If you are viewing this manual online, you can use the print feature to print this worksheet. The following sections explain the information you need to record on the worksheet.

Figure 5–3: Basic DHCP Parameters Worksheet

Basic DHCP Parameters Worksheet	
Configuration type:	Node <input type="checkbox"/> Subnet <input type="checkbox"/> Group <input type="checkbox"/>
Configuration name:	_____
Member of group:	_____
Group members:	_____
Net or subnetwork IP address:	_____
Hardware address:	_____
Hardware type:	_____
BOOTP Parameters	
Boot file:	_____
Boot file server address:	_____
Boot file size:	_____
DNS domain name:	_____
DNS server IP addresses:	_____

Home directory:	_____
Host IP address:	_____
Routers:	_____

Send client's host name:	True <input type="checkbox"/> False <input type="checkbox"/>
Subnetwork mask:	_____
TFTP root directory:	_____
Broadcast address:	_____
Subnetworks are local:	True <input type="checkbox"/> False <input type="checkbox"/>
Supply masks:	True <input type="checkbox"/> False <input type="checkbox"/>
DHCP rebinding time:	_____
DHCP renewal time:	_____
Lease time:	_____

Configuration type

For node configuration, check Node. For subnetwork configuration, check Subnet. For group configuration, check Group.

Configuration name

The name of the node, group, or subnetwork.

Member of group

For node, subnetwork, and group configurations, the name of a configuration from which to inherit DHCP parameter values. Parameters defined for that group also apply to this configuration.

Group members

For group configuration, the nodes, subnetworks, and groups that compose this group.

Net or subnetwork IP address

For subnetwork configuration, the IP address of the subnetwork. The IP address format is *ddd.ddd.ddd.ddd*. For example, if your subnetwork is 16.128, enter 16.128.0.0; you must include the trailing zeros.

Hardware address

For node configuration, the Ethernet address of the client node.

Hardware type

For node configuration, a descriptive name to identify the system.

For node, subnetwork, and group configuration, BOOTP parameters allow you to specify how to pass configuration information to hosts on the network. For BOOTP parameters, supply the following information:

Boot file

The fully qualified path name of the client's default boot image.

Boot file server address

The IP address of the server that stores the boot file. The IP address format is *ddd.ddd.ddd.ddd*.

Boot file size

The length, in 512-octet blocks, of the default boot image for the client. The file length is specified as a decimal number.

DNS domain name

The domain name the client uses when resolving host names using the Domain Name System.

DNS server IP addresses

A list of IP addresses of DNS name servers available to the client, in order of preference. The address format is *ddd.ddd.ddd.ddd*.

Home directory

The pathname for the boot file, if it is not specified in the boot file name.

Host IP address

The host IP address for BOOTP clients. The address format is *ddd.ddd.ddd.ddd*.

Routers

A list of IP addresses for routers. The address format is *ddd.ddd.ddd.ddd*.

Send client's host name

If you want to send the client's host name, check True. If you do not want to send the client's host name, check False.

Subnetwork mask

The client's subnetwork mask. A subnetwork mask allows the addition of subnetwork numbers to an address, and provides for more complex address assignments. If both the subnetwork mask and the router option are specified in a DHCP reply, the subnetwork mask option must be specified first. The subnetwork mask format is *ddd.ddd.ddd.ddd*.

TFTP root directory

The root directory for Trivial File Transfer Protocol (TFTP).

For subnetwork and group configuration, IP layer parameters affect the operation of the IP layer on a per-host basis. The required IP layer parameters are as follows:

Broadcast address

The broadcast address in use on the client's subnetwork. The address format is *ddd.ddd.ddd.ddd*.

Subnetworks are local

If all subnetworks of the IP network to which the client is connected use the same maximum transfer unit (MTU) as the subnetwork to which the client is directly connected, check True; otherwise, check False. It is recommended for the client to assume that some subnetworks of the directly connected network have smaller MTUs.

Supply masks

If the client responds to subnetwork mask requests using ICMP, check True; otherwise, check False.

For a list of additional parameters and a description of each, see the *JOIN Server Administrator's Guide* (`/usr/doc/join/TOC.html`).

For node, group, and subnetwork configuration, lease parameters allow you to specify information about IP lease times. Lease times determine the length of time an IP address is used. For the lease parameters, supply the following information:

DHCP rebinding time

The time interval (in seconds) from address assignment until the client requests a new lease from any server on the network.

DHCP renewal time

The time interval (in seconds) from address assignment until the client attempts to extend the duration of its lease with the original server.

Lease time

The amount of time (in months, days, hours, minutes, and seconds) the DHCP server will allow a DHCP client to use an IP address; for example, 2 months 5 days 45 minutes. The actual lease time is negotiated between the client and server.

5.3 Configuring a DHCP Server

Use the `xjoin` application to configure a DHCP server. To start the application, enter the following command:

```
# /usr/bin/X11/xjoin
```

You can configure the following server information:

- Server/Security parameters
- IP ranges
- Host names
- Subnetworks
- DHCP client nodes
- Groups

To update the server so that the new configuration takes effect, click on the Add/Update button in the lower right-hand side of the window. To

exit the application, select File and Exit from the menu bar. See the `xjoin(8)` reference page and the *JOIN Server Administrator's Guide* (`/usr/doc/join/TOC.html`) for more information.

5.3.1 Configuring Server/Security Parameters

To configure the Server/Security parameters, do the following:

1. Click on the Server/Security tab in the `xjoin` main window.
2. Select the Server item from the left side of the window.
3. Select Server/Security parameters from the pull-down menu.
4. Select a server parameter.
5. Select True or False, or enter a value.
6. Repeat steps 4 and 5 for all server parameters you want to configure.
7. Click on the Add/Update button to update the server with the new Server/Security parameters.

5.3.2 Configuring IP Ranges

To configure IP ranges, do the following:

1. Click on the Server/Security tab in the `xjoin` main window.
2. Select the Server item from the left side of the window.
3. Select IP Ranges from the pull-down menu.
4. Select the New IP Range item.
5. Enter the subnetwork address, server address, and IP range. For each IP range, do the following:
 - a. Enter the beginning of the IP Address Range for the subnetwork (network, subnetwork, and host address).
 - b. Press the Tab key to move to the next field.
 - c. Enter the end of the IP Address Range.
6. Repeat steps 4 and 5 for each new IP range.
7. Click on the Add/Update button to update the server with new IP ranges.

5.3.3 Configuring Host Name Lists

You configure host name lists only if the Accept Client Name server parameter is set to False. If the Accept Client Name server parameter is set to True, the server automatically accepts the name a client suggests for itself; do not configure host name lists.

To configure a host name list, do the following:

1. Click on the Server/Security tab in the `xjoin` main window.
2. Select the Server item from the left side of the window.
3. Select Hostname Lists from the pull-down menu.
4. Select the New Hostname List item.
5. Enter the domain name, DHCP server name, host name prefix, and host names for each host name list.
6. Repeat steps 4 and 5 for each host name.
7. Click on the Add/Update button to update the server with new host name lists.

5.3.4 Configuring a Subnetwork

To configure a subnetwork, do the following:

1. Click on the Subnets tab in the `xjoin` main window.
2. Select the New Record item from the left side of the window.
3. Select the Name parameter. Enter the name of the subnetwork configuration, for example, Subnet3.
4. Select the Member of Group parameter. Enter the name of the group of which the subnetwork will be a member.
5. Select the Net or Subnet IP Address parameter. Enter the Net or Subnet IP address that identifies the subnetwork portion of the network.
6. Select the Broadcast Address parameter. Enter the broadcast address for this subnetwork.
7. Enter information for basic DHCP parameters in the appropriate fields. See Section 5.2.2 and the *JOIN Server Administrator's Guide* (`/usr/doc/join/TOC.html`) for descriptions of these parameters.
Note that you do not have to change each parameter value in the Subnets tab; only those that describe your particular network configuration.
8. Click on the Add/Update button to update the server with new subnetwork configuration information.
9. Edit the `/etc/join/netmasks` file and add an entry for each subnetwork in your network. The format of each entry is as follows:

```
subnet_address subnet_mask
```

5.3.5 Configuring a DHCP Client Node

To configure a node, do the following:

Note

A cluster member must never be a DHCP client. Use static addressing for cluster members..

1. Click on the Nodes tab in the `xjoin` main window.
2. Select the New Record item from the left side of the window.
3. Select the Name parameter. Enter the name of the node configuration; for example, Client5.
4. Select the Hardware Type parameter. Enter the type of network to which the node is connected; for example, Token Ring, Ether3, Pronet, Arcnet, or 0.
5. Select the Hardware Address/Client ID parameter. Enter the hardware address or the client ID of the node. If the Hardware Type defined in the previous step is zero, enter the Client ID (an alphanumeric string that you define).

If you are using the hardware address (MAC address) of the node, enter it in the format `nn:nn:nn:nn:nn:nn` (for instance, `08:00:26:75:31:81`). The hardware address is assigned when a workstation is manufactured, and is often displayed when the workstation is turned on or rebooted. The hardware address is also called the Ethernet address.

6. Select the Member of Group parameter. Enter the name of the group of which the node will be a member.
7. Enter information for basic DHCP parameters. See Section 5.2.2 and the *JOIN Server Administrator's Guide* (`/usr/doc/join/TOC.html`) for descriptions of these parameters.

Note that you do not have to change each parameter value in the Nodes tab, only those that describe your particular network configuration.

8. Click on the Add/Update button to update the server with new node configuration information.

Depending on the DHCP client, the MAC address field is not always the actual MAC address of the client's network adapter. The following Microsoft clients are known to modify the MAC address before sending it to the server:

- Windows 95
- Windows NT
- Windows for Workgroups with Microsoft TCP/IP

These clients prefix the MAC address with the hardware type. The MAC address type is 0 and the length is 7 (instead of 6). For example, if your

Ethernet address is 11:22:33:44:55:66, you must specify the following for static IP mapping:

- MAC address: 01:11:22:33:44:55:66
- MAC type: 0
- MAC length: 7

If you do not specify the MAC address in this manner, the client will fail to collect an IP address from the DHCP server.

See the documentation for your Microsoft product for more information.

5.3.6 Setting Group Parameters

To define a group, do the following:

1. Click on the Groups tab in the `xjoin` main window.
2. Select the New Record item from the left side of the window.
3. Select the Name parameter. Enter the name of the group configuration; for example, Global.
4. Select the Member of Group parameter. If appropriate, enter the name of the group of which that the new group will be a member.
5. Select the Group Members parameter. Enter the names of subnetworks, nodes, or other groups that will be members of the group. Press the Tab key between entries.
6. Enter information for basic DHCP parameters. See Section 5.2.2 and the *JOIN Server Administrator's Guide* (`/usr/doc/join/TOC.html`) for descriptions of these parameters.

Note that you do not have to change each parameter value in the Groups tab, only those that describe your particular network configuration.

7. Click on the Add/Update button to update the server with new group configuration information.

5.4 Starting the DHCP Server (joind)

After you install the OSFINET optional subset, run the installation script, and configure the server, use the SysMan Menu application of the Common Desktop Environment (CDE) Application Manager to start the DHCP server and implement the new configuration. To invoke the SysMan Menu application, follow the instructions in Chapter 1.

To start the DHCP server, do the following:

1. From the SysMan Menu, select Networking→Additional Network Services→Set up the system as a DHCP Server (joind) to display the DHCP Server Daemon dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman joind
```

The utility asks if you want this system to be a DHCP server.

2. Select the Yes radio button to enable the joind daemon.
3. Set the debugging level. The default is 0 for no debugging information. Higher numbers produce more detailed debugging information.
4. Set the Log Level by selecting the appropriate radio button.
5. Select OK to save the changes and enable the joind daemon. You are informed that the daemon is running.
6. Select OK to dismiss the message and close the DHCP Server Daemon dialog box.

The DHCP Server Daemon dialog box also allows you to disable and stop the joind daemon. See the SysMan Menu online help for additional information.

Caution

Do not use the `kill -9` command to stop the DHCP server daemon; it can corrupt your database files. Use the Configuring DHCP Server Daemon dialog box or the `kill -HUP` command instead.

See the `joind(8)` reference page for more information about the joind daemon.

5.5 Starting the DHCP Client

When you use the SysMan Menu application to configure the basic network connections on the client system, you must specify an Internet address source. If you specify DHCP server and restart the network, the DHCP client daemon starts and uses DHCP to obtain IP configuration information. From then on, the DHCP client automatically starts each time the client computer boots.

5.6 Monitoring DHCP Client Configuration

After the initial DHCP server configuration, you can check the status of a DHCP client by examining the contents of the `/var/xdnsd/log` file or by doing the following:

1. Log in as root to the DHCP server host.
2. Invoke the `xdnsd` application by entering the following command:

```
# /usr/bin/X11/xdnsd
```
3. Click on the Server/Security tab in the `xdnsd` main window.
4. Select Active IP Snapshot from the pull-down menu. The Active IP Snapshot window is displayed, listing each configured DHCP client.
5. Click on a record on the left side of the window to display all current configuration information for the client.

You can also use the `xdnsd` application to modify client configuration information, permanently map a hardware address to an IP address, import a file into the active IP database, and remove records from this window. See the `xdnsd(8)` reference page and the *JOIN Server Administrator's Guide* (`/usr/doc/xdnsd/TOC.html`) for more information.

5.7 Mapping Client IP Addresses Permanently

Typically, a client is assigned the first available IP address from the pool of IP addresses. However, you might want to permanently assign an IP address to a client's hardware address or Media Access Control (MAC) address. The IP address mapped to a hardware address does not need to come from the IP addresses you have already defined. To permanently map an IP address to a client's hardware address, do the following:

1. Log in as root to the DHCP server.
2. Invoke the `xdnsd` application by entering the following command:

```
# /usr/bin/X11/xdnsd
```
3. Click on the Server/Security tab in the `xdnsd` main window.
4. Select Active IP Snapshot from the pull-down menu. The Active IP Snapshot window is displayed.
5. Select the New Record item.
6. Enter a value for each parameter. Press the Return or Tab key after each entry. Specify the integer `-1` for Lease Expiration to ensure that the IP address assignment is preserved in the DHCP database (it will never expire).
7. Click on the Add/Update button to add the new record to the database.

8. Repeat steps 5, 6, and 7 for each MAC address you want to permanently map.

5.8 Restricting Access to the DHCP Server

You restrict client access to the DHCP server only if you set the Restrict to Known MAC Address server parameter to True. (See Section 5.2.2.1.) If you set the Restrict to Known MAC Address server parameter to True, you must create a list of MAC addresses that can access and accept IP address assignments from the DHCP server. If you set the server parameter to False, do not create a list of MAC addresses.

To create a list of MAC addresses that can access the DHCP server, do the following:

1. Click on the Server/Security tab in the `xjoin` main window.
2. Select Preload MAC Addresses from the pull-down menu. The Preload MAC Addresses window is displayed.
3. Select the New Record item.
4. Enter a value for each parameter. Press the Return key after each entry.
5. Click on the Add/Update button to add the new record to the database.
6. Repeat steps 3, 4, and 5 for each MAC address that you want to access the DHCP server.

Alternatively, you can import a file into the MAC address database by using the `jdbmod` command. See the `jdbmod(8)` reference page for information on the imported file format.

To remove records from the MAC address database, select a MAC address from the left side of the window and click on the Delete button.

5.9 Configuring a BOOTP Client

To register a client to use BOOTP only, do the following:

1. Log in as root.
2. Invoke the `xjoin` application by entering the following command:

```
# /usr/bin/X11/xjoin
```
3. Click on the Nodes tab in the `xjoin` main window.
4. Enter BOOTP client information, including the boot file name, host IP address, subnetwork mask, and any other required information. The basic BOOTP parameters are grouped together below the Key parameters in the middle column. To display additional parameters,

click on the Basic DHCP Parameters pull-down menu and select DHCP Parameters.

5. Click on the File/Update button to update the server with the BOOTP client information.

5.10 Disabling DHCP Address Assignment

In some cases, you might want to disable DHCP address assignment and use the BOOTP and DHCP server daemon (`/usr/sbin/iscdhcpd`) to respond to BOOTP requests only. To disable all DHCP address assignment features in the DHCP and BOOTP server, do not specify an IP address range for any subnetwork (this is the default). If no IP address ranges are defined, the server never sends a DHCP reply in response to a DHCP client request.

If DHCP address assignment is disabled, DHCP clients that have previously registered with this server continue to operate until their leases timeout; the server will fail to renew the client lease.

Point-to-Point Connections

The Tru64 UNIX system supports point-to-point connections using the Serial Line Internet Protocol (SLIP) and the Point-to-Point Protocol (PPP).

This chapter describes:

- The SLIP and PPP environments
- How to configure SLIP and PPP dial-in and dial-out systems
- How to configure a modem for use with the operating system

For troubleshooting information, see Section 15.15 for SLIP and Section 15.16 for PPP.

6.1 Serial Line Internet Protocol (SLIP)

The Serial Line Internet Protocol (SLIP) is a protocol used to run IP over serial lines between two hosts. You can connect the two hosts either directly or over telephone circuits using modems. TCP/IP commands (such as `rlogin`, `ftp`, and `ping`) can be run over the SLIP connection.

6.1.1 SLIP Environment

In the SLIP environment, systems can be directly connected to each other, if they are in close proximity, or connected through modems and a telephone network, if they are not. Figure 6–1 shows both of these simple SLIP configurations. Figure 6–2 shows a SLIP connection between two systems with host B acting as a gateway system.

Figure 6–1: Sample Simple SLIP Configuration

Figure 6–2: SLIP Configuration with Gateway System

6.1.2 Planning SLIP

This section describes those tasks you must complete before configuring SLIP.

6.1.2.1 Verifying the Hardware

When you verify the hardware, you need to verify both the cables and modems, if used.

Make sure you use the correct cable to connect to the serial port of your system. If you do not, you might experience signal degradation and the software will fail to function properly.

If the two systems are in close proximity to each other, use one of the null modem cables listed in Table 6–1.

Table 6–1: Types of Null Modem Cable

Cable Number	Description
BC22D-xx ^a	Asynchronous null modem cable (male DB25 pin to female DB25 pin cable)
BC22R-xx ^a	RS-232 null modem cable (male DB25 pin to female DB25 pin cable)
BC24C-xx ^a	25-wire null modem cable (male DB25 pin to female DB25 pin cable)
BC29Q-xx ^a	Male DB9 pin to female DB9 pin cable

^a xx denotes the cable length. For example, BC29Q-10 is a ten-foot cable.

If the two systems are connected through modems and telephone lines, see Table 6–7 for a list of modem cables to use.

When using modems with SLIP, adhere to the following guidelines:

- Use modems that can handle a serial port speed of 38,400 bits per second (bps). If the modems you plan to use cannot handle a serial port speed of 38,400 bps, set them to the highest speed to which they can be set.
- Use modems that are V.34bis compliant with V.42bis compression. Alternatively, you can use modems that support the Microcom Network Protocol (MNP) because both V.42bis and MNP implement a subset of the other protocol.
- Set the modems to 8 bits, no parity, and connect them to the telephone network.
- Use hardware flow control, if possible. High-speed modems often fall back to a lower data rate when line degradation occurs.

Note

Do not use software flow control (XON/XOFF). It will corrupt the data stream causing the TCP layer over IP to issue retransmit requests for overruns.

6.1.2.2 Preparing for the Configuration

After you verify the communication hardware, you can set up the system to run SLIP.

Figure 6–3 shows the SLIP Setup Worksheet, which you can use to record the information that you need to configure SLIP. The following sections explain the information you need to record on this worksheet. If you are viewing this manual online, you can use the print feature to print the worksheet.

Figure 6–3: SLIP Setup Worksheet

SLIP Setup Worksheet	
Type of connection:	<input type="checkbox"/> Hardwired <input type="checkbox"/> Modem
Type of system:	<input type="checkbox"/> Dial-in <input type="checkbox"/> Dial-out
Local IP address:	_____
Network mask:	_____
Destination IP address:	_____
Terminal name:	_____
Speed:	_____
SLIP login information:	_____
Dialout systems	
startslip subcommands:	_____

Dialin systems	
slhosts file options:	_____
Gateway:	<input type="checkbox"/> Yes <input type="checkbox"/> No

Type of connection

Check Hardwired if the two systems are connected by a null modem cable, such as BC22D-xx. Check Modem if the two systems are connected by modem cables, modems, and a telephone network.

Type of system

Check dial-in if the system is to answer calls from remote systems. Check dial-out if the system is to place calls to a remote system.

Local IP address

Your system's SLIP interface IP address. Each SLIP interface must have an IP address. For more information on SLIP, see the *Technical Overview* and `startslip(8)`.

Network mask

Your network's subnetwork mask. This must be the same for both systems. See Section 2.2 for more information on the network mask.

Destination IP address

The destination system's SLIP interface IP address.

Terminal name

The name of a valid terminal device in the `/dev` directory that has a cable connection. This can be either the full path name (for example, `/dev/tty00`) or the name in the `/dev` directory (for example, `tty00`). For more information on the terminal line specification, see `startslip(8)`. If you are unsure of the terminal device, see `port(7)`.

Speed

The serial port speed used to connect the systems to each other or a system and the modem. The default speed is 9600 bps. For more information on the speed, see `startslip(8)`.

SLIP login information

The login information for the SLIP connection. This includes user name, password, and login sequence; for example, the login prompt used on dial-out connections.

startslip subcommands

For dial-out systems, Table 6-2 shows the mandatory `startslip` subcommands that you specify when you create a setup script file. Table 6-3 shows the optional `startslip` subcommands.

Table 6-2: Mandatory `startslip` Subcommands

Subcommand	Information Required
<code>myip</code>	Your system's IP address.
<code>dstip</code>	The destination system's IP address.
<code>netmask</code>	The network mask for the subnetwork.

Table 6–2: Mandatory startslip Subcommands (cont.)

Subcommand	Information Required
hardwired	None. Specifies that the two systems are connected by a null modem cable.
modemtype	The type of modem used, unless you have a direct connection.
opentty	The serial line and line speed.
dial	The telephone number to dial.
expect	The information that you expect to receive on the serial line; for example, login sequences.
send	The information that you want to send on the serial line.
connslip	Configures the network interface and attaches the serial line to the network interface.

Table 6–3: Optional startslip Subcommands

Subcommand	Description
debug	Generates debugging messages to the log file specified.
gateway	Specifies that the destination system is a gateway to another system on a LAN.
icmpsup	Suppresses Internet Control Message Protocol (ICMP) traffic. ICMP traffic (such as that generated by the ping command) cannot be sent over the SLIP connection. This frees line bandwidth for more critical traffic.
tcpauto	Specifies that the local system compress TCP headers when it detects that the remote system is compressing them. This option can be useful if you do not know whether the remote system is doing TCP header compression. Note: If the tcpauto option is enabled on both systems, TCP header compression does not occur. One of the two systems must explicitly enable TCP header compression.
tcpcomp	Compresses TCP headers before they are sent over the SLIP connection. Compressing the TCP header allows for faster data transfers. The remote system must support this option to decompress the headers when they arrive at the remote end.

See `startslip(8)` for a complete list of the `startslip` subcommands.

slhosts file options

For dial-in systems, Table 6–4 shows a list of options for each SLIP link specified in the `/etc/slhosts` file.

Table 6–4: slhosts File Options

Option	Description
<code>debug</code>	Generates debugging messages to the <code>daemon.log</code> file.
<code>icmpsup</code>	Suppresses Internet Control Message Protocol (ICMP) traffic. ICMP traffic (such as that generated by the <code>ping</code> command) cannot be sent over the SLIP connection. This frees line bandwidth for more critical traffic.
<code>tcpauto</code>	Specifies that the local system compress TCP headers when it detects that the remote system is compressing them. This option can be useful if you do not know whether the remote system is doing TCP header compression. This is the default.
<code>tcpcomp</code>	Compresses TCP headers before they are sent over the SLIP connection. Compressing the TCP header allows for faster data transfers. The remote system must support this option to decompress the headers when they arrive at the remote end. Do not specify the <code>tcpcomp</code> and <code>tcpauto</code> options together.

See `slhosts(4)` for more information.

Gateway

For dial-in systems, if your system is to act as a gateway for a dial-out system to access the LAN, check Yes; otherwise, check No.

6.1.3 Configuring SLIP

To configure SLIP, you must have verified the communications hardware and completed the configuration worksheet.

A system in a SLIP environment can have one of the following roles:

- Dial-in system
- Dial-out system

You edit system files and use the `startslip` program to configure both dial-in connections and dial-out connections.

6.1.3.1 Configuring a Dial-In System

To configure a dial-in system, log in as root and complete the following steps:

1. Set up your modem for dial-in access. See Section 6.3.2 for more information.

Note

Use a `getty` process for SLIP dial-in access.

2. Edit the `/etc/passwd` file and create a dedicated entry for a SLIP user. For the login shell field, specify `/usr/sbin/startslip`. The login name you specify here is used to find an entry in the `/etc/slhosts` file, for example:

```
slip1:password:10:20:Remote SLIP User:/usr/users/guest:/usr/sbin/startslip
```

3. Edit the `/etc/slhosts` file and create an entry for the login name using the information from the worksheet. An `/etc/slhosts` file entry has the following syntax:

login_name remote_ip local_ip netmask option

For example, if host D is the dial-in system in Figure 6–1, the entry is as follows:

```
slip1 1.2.3.6 1.2.3.5 255.255.255.0 nodebug
```

See `slhosts(4)` for more information.

4. Edit the `/etc/inittab` file and create an entry for each terminal device that is to run SLIP. An `/etc/inittab` file entry has the following syntax:

Identifier:Runlevel:Action:Command

For example:

```
modem:3:respawn:/usr/sbin/getty /dev/tty00 M38400 vt100
```

See `inittab(4)` for more information.

5. Issue the `init q` command to start the `getty` process immediately.
6. If the dial-in system will be a gateway for the dial-out system to reach other systems on the LAN, the dial-in system must be configured as an IP router and must also run `gated`. See Chapter 2 for basic network setup information.

If problems occur while using SLIP, see Section 15.15.

6.1.3.2 Configuring a Dial-Out System

To configure a dial-out connection, log in as root and complete the following steps:

1. Verify that there is an entry for your modem name in the `/etc/acucap` file. If your modem does not have an entry in the `/etc/acucap` file, do the following:
 - a. Copy an entry similar to that of your modem.
 - b. Modify the modem attributes to match your modem's attributes. Set up the modem for dial-out access by including the AT commands listed in Table 6–5 in the synchronization string (`ss`) of the entry. The other modem settings can remain as they are.

Table 6–5: Modem Commands for Dial-Out Access

Command	Description
<code>at&c1</code>	Normal Carrier Detect (CD) operation. Tells the modem to not raise Carrier Detect until it sees Carrier Detect from the other modem.
<code>at&d2</code>	Normal Data Terminal Ready (DTR) operation. This tells the modem to hang up the line when DTR drops; for example, when the user logs off the system.
<code>ate1</code>	Turns on echoing.
<code>atq0</code>	Displays the result codes.
<code>ats0=0</code>	Does not answer the phone.

In addition, include the debug option (`db`). With debugging turned on, the modem will provide you with additional information with which to tune the modem attributes in the file. See `acucap(4)` for more information.

2. If you use the `getty` command to provide access to the system from a modem and a `getty` process is already running, do the following:
 - a. Edit the `/etc/inittab` file and change the Action field of the modem entry from `respawn` to `off` as follows:

```
modem:23:off:/usr/sbin/getty /dev/tty00 M38400 vt100
```

See `inittab(4)` for more information.
 - b. Issue the `init q` command to terminate the `getty` process.

3. Create a file that contains `startslip` subcommands for SLIP dial-out connections by doing the following:
 - a. Copy the sample script file from the `startslip(8)` reference page to a new script file.
 - b. Use the `tip` command to dial out and log in to the remote system, writing down the exact prompt and login sequence on the worksheet.
 - c. Edit the script file, modify the `expect` subcommands with the prompt and login information, and modify other subcommands with information from the worksheet.

Note

The sample script file specifies the `debug` subcommand and a debug file name at the beginning of the file.

See `startslip(8)` for more information.

4. Invoke the `startslip` command with the `-i filename` option. The *filename* is the name of the file containing the `startslip` subcommands.

After making the connection, `startslip` runs in the background. The telephone number (if any) and the process ID are logged in the `/var/run/ttyxx.tel-pid` file.

If problems occur while using SLIP, see Section 15.15.

6.1.4 Terminating a SLIP Dial-Out Connection

To terminate a SLIP dial-out connection, do the following:

1. Determine the process ID of the `startslip` process to kill by using the following command:

```
# cat /var/run/ttyxx.tel-pid
phonenum 8021455 pid 821
```

In the previous command, `ttyxx` specifies the terminal line used for the SLIP connection. If multiple SLIP connections are active on your system, there will be multiple files in the `/var/run` directory.

2. Kill the `startslip` process by using the following command and specifying the process ID that you found in step 1:

```
# kill 821
```

Alternatively, you can turn off your modem to terminate the dial-out connection.

6.2 Point-to-Point Protocol (PPP)

The Point-to-Point Protocol (PPP) provides a standard way to transmit datagrams over a serial link and a standard way for the systems at either end of the link (peers) to negotiate various optional characteristics of the link. Using PPP, a serial link can be used to transmit Internet Protocol (IP) datagrams, allowing TCP/IP connections between the peers.

The Tru64 UNIX PPP subsystem is derived from public domain ppp-2.3.1, and supports IP datagrams. See RFC 1661, RFC 1662, RFC 1332, and RFC 1334 for more information about PPP.

Establishing a PPP connection between two systems basically involves setting up a serial link and running `pppd` on both ends of the link.

Systems in a PPP environment can have the following roles:

- Dial-out system
- Dial-in system

6.2.1 PPP Environment

Systems using PPP can be directly connected to each other if they are in close proximity, or connected through modems and a telephone network if they are not. Figure 6-4 shows two simple PPP configurations with PPP connections between two systems.

Figure 6-4: Simple PPP Configurations

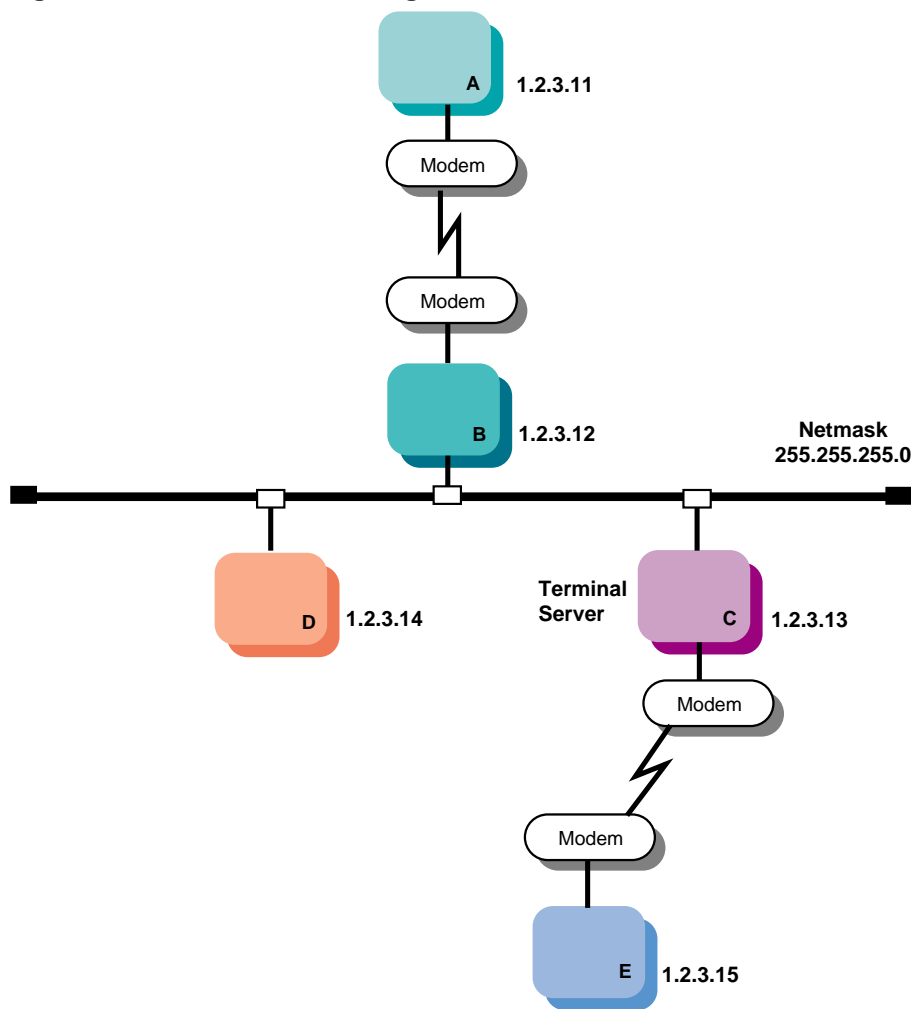

Figure 6-5 shows two PPP connections. The first is between host A and host B, with host B acting as a gateway system. The second is between personal computer E and host D through terminal server C. The latter configuration

might be common for employees working at home and dialing in to a system at work.

Figure 6–5: Network PPP Configuration

ZK-1176U-AI

6.2.1.1 Chat Scripts

A chat script can be used to automate the dial-out process for a PPP connection. You can configure it to wait for output from a remote system and reply with responses that you specify.

Each entry in a chat script has the following format:

string_chat_expects string_chat_sends

For example, a chat script might contain the following information:

```
" atdt2135476 1
CONNECT 2
login: myname 3
Password: "\qmypassword" 4
"$ " "\qpppd" 5
"\qpppd" local_addr:6
```

When this chat script is executed, the following steps are taken:

- 1 The chat program expects nothing and sends a dial command to the modem.
- 2 The chat program expects a CONNECT message and sends a carriage return (implied).
- 3 The chat program expects the login: string and sends the *myname* string.
- 4 The chat program expects the Password: string and sends the *mypassword* string. The \q prevents chat from logging the password when you use the -v option.
- 5 The chat program expects the shell prompt (\$) and sends pppd to start the pppd daemon on the remote machine. The \q cancels the effect of the previous \q.
- 6 If you want the local address of the PPP link to differ from the IP address for the local host's Ethernet or other broadcast interface, put the desired address on the pppd command line with a colon appended.

You can create a unique chat script for each remote system to which you connect. Once the scripts are created, you establish a PPP connection to a given system by executing the appropriate script with the chat command, as follows:

```
# chat /etc/ppp/chat-script
```

See the chat(8) reference page for more information on the chat command and chat scripts.

6.2.1.2 PPP Options

When you invoke the pppd daemon, you can specify options for it on the command line. These options allow you to configure basic settings such as the speed of the connection, the local and remote IP addresses, and the netmask for the network interface. They also allow you to configure advanced settings such as the types of flow control, authentication, and routing to use.

If you use certain settings each time you initiate a PPP connection, you can automatically enable these settings for each connection by editing the following files:

- `/etc/ppp/options` — This file contains system default options that are read before user default options and command line options. This file contains any options that you want `pppd` to use whenever it runs. If authentication is required, add the `auth` and `usehostname` options to this file.

Note

If the `/etc/ppp/options` file does not exist or is unreadable by `pppd`, the daemon will not run. Set the file permissions so that only root has write access.

- `/etc/ppp/options.tty.xx` — This file contains options specific to the serial port `/tty.xx`.
- `$HOME/.ppprc` — This file contains the user default options that are read before command line options.

Depending on your configuration, one options file might overrule another for certain parameters. For example, if you specify one set of values for parameters in the `/etc/ppp/options` file, then specify a different set of values for the same parameters in a `/etc/ppp/options.tty.xx` file, the settings in the latter file are used when you connect through the specified serial port.

See `pppd(8)` for a list of the `pppd` options. See Section 6.2.3.2 for information about how to use the SysMan Menu utility to create options files.

6.2.1.3 Authentication

PPP provides three protocols for authenticating hosts and for authenticating your host system to others:

- Password Authentication Protocol (PAP)
- Challenge Handshake Authentication Protocol (CHAP)
- Microsoft Challenge Handshake Authentication Protocol (MS-CHAP)

All protocols exchange secrets in order to complete the authentication process. PAP secrets are contained in the `/etc/ppp/pap-secrets` file; CHAP secrets are contained in the `/etc/ppp/chap-secrets` file. Set the file permissions on these files so that only root has read access.

The `/etc/ppp/pap-secrets` and the `/etc/ppp/chap-secrets` files for PAP and CHAP have the following format:

client server secret ip_address...

- *client* — Name of the machine to be authenticated
- *server* — Name of the machine requiring the authentication
- *secret* — Password or CHAP secret known by both client and server
- *IP address* — Zero or more IP addresses that the client can use (this field is only used on the server)

For example, if a LAN-connected host named `work` requires authentication, and a host named `home` connects to it and authenticates itself using CHAP, the `/etc/ppp/chap-secrets` file on each machine must contain an entry similar to the following:

```
home work "an unguessable secret" home.my.domain
```

Note

The `/etc/ppp` directory contains files of secrets used for authentication, and must not be in a partition that is exported using NFS and accessible by other hosts.

If authentication is required, the `/etc/ppp/options` file must contain the `auth` and `usehostname` options.

Note, the MS-CHAP protocol exchange secrets are located in the `/etc/ppp/chap-secrets` file. The format for this protocol is as follows:

username server secret

- *username* — User name of the user to be authenticated
- *server* — Name of the machine requiring the authentication
- *secret* — Password or CHAP secret known by both client and server

6.2.2 Planning PPP

This section describes the tasks you must complete before configuring PPP.

6.2.2.1 Verifying the Hardware

Verify that you have the hardware to connect to the serial port of your system. If the two systems are in close proximity to each other, use one of the null modem cables listed in Table 6-1.

If the two systems are connected through modems and telephone lines, see Table 6-7 for a list of modem cables to use. The modems are set to 8 bit, no parity, and are connected to the telephone network.

6.2.2.2 Verifying PPP Support in the Kernel

To verify that PPP is supported in the kernel, enter the following command:

```
# sysconfig -s | grep ppp
```

If PPP is not loaded and configured, do the following:

1. Log in as root.
2. Rebuild the kernel by running the `doconfig` utility and selecting the Point-to-Point (PPP) option.
3. Make a backup copy of the current `/vmunix` kernel file.
4. Copy the newly-created `/sys/HOSTNAME/vmunix` kernel file to the `/vmunix` file.
5. Reboot the system.

6.2.2.3 Preparing for Configuration

After you verify PPP support in the kernel, you can configure PPP.

Figure 6–6 shows the PPP Setup Worksheet, which you can use to record the information that you need to configure PPP. The following sections explain the information you need to record on this worksheet. If you are viewing this manual online, you can use the print feature to print the worksheet.

Figure 6–6: PPP Setup Worksheet

PPP Setup Worksheet	
Type of system:	<input type="checkbox"/> Dial-in <input type="checkbox"/> Dial-out
Local IP address:	_____
Remote IP address:	_____
Network mask:	_____
Terminal name:	_____
Speed:	_____
Level of authentication:	_____
Type of authentication:	<input type="checkbox"/> PAP <input type="checkbox"/> CHAP
Options:	_____

Type of system

- Check dial-in if the system is to answer calls from remote systems.
- Check dial-out if the system is to place calls to a remote system.

Local IP address

The local system's IP address. For systems connected to a local area network (LAN), this address is already assigned if you configured your network software; it is the IP address of the LAN interface.

If you have a standalone system, you must assign it an IP address. If you are using PPP to link your system to a host that is connected to the Internet, assign the local system an address that is on the same subnetwork as the remote host. If the other host is not connected to the Internet, assign the local system any IP address.

Remote IP address

The remote system's IP address.

Network mask

Your network's subnetwork mask. This must be the same for both systems. See Section 2.2 for more information on the network mask.

Terminal name

The name of any valid terminal device in the `/dev` directory. This can be either the full path name (for example, `/dev/tty01`) or the name in the `/dev` directory (for example, `tty01`). If you are unsure of the terminal device, see `ports(7)` for more information.

Speed

The speed of the modem (or null modem) used to connect the systems and the terminal line specification. If your modem automatically senses the line speed or if you are using a null modem cable between hosts, you can specify any speed up to the maximum supported by the hosts. This is usually 38400 bps.

Level of authentication

The level of authentication required. In general, if your system is connected to a LAN, it is best to require the remote host to authenticate itself and to restrict the remote host's choice of IP address based on its identity. Otherwise, a remote host might impersonate another host on the local subnet.

Note

If you are configuring PPP for the first time, do not enable authentication until you can successfully establish a link.

Type of authentication

If you are using PAP authentication, check PAP. If you are using CHAP authentication, check CHAP.

Options

Table 6–6 describes some advanced options that are commonly configured. You can use the SysMan Menu utility to configure these options, as described in Section 6.2.3.2.

Table 6–6: sllhosts File Options

Option	Description
Async Character Conversion Map (asyncmap)	If the serial line is not completely 8-bit transparent, specify this option; <code>asyncmap 200a000</code> is appropriate if the serial link includes a <code>telnet</code> link.
Maximum Receive Unit (MRU) Negotiation	To improve performance for multiple IP connections, reduce the Maximum Receive Unit (MRU) on the local and remote system. It is best to set the MRU value to 296.
Hardware Flow Control(RTS/CTS)	Enables hardware flow control on the serial device. If the modem does not support hardware flow control, do not add this entry. See your modem documentation to verify this information.
LCP Echo-Request Interval (lcp-echo-interval)	Sends a Link Control Protocol (LCP) echo request frame to the remote system every 60 seconds. This determines whether the link to the remote system is still active.
Maximum LCP-Echo Requests (lcp-echo-failure)	If the local system does not receive a response from the remote system after five LCP echo request frames, <code>pppd</code> considers the link dead and tears down the connection.
Force peer to supply local IP address (noipdefault)	Specifies that the remote system (ISP) is to provide the local system an IP address, unless an IP address is specified explicitly on the command line or in an options file.
Enable debugging (debug)	Enables debugging. All messages are sent to the file specified in the <code>/etc/syslog.conf</code> file. After your connection is working correctly, remove this entry.

See `pppd(8)` for a complete list of `pppd` options.

6.2.3 Configuring a Dial-Out System with PPP

If the system will place calls to a remote system, you must establish a dial-out connection, which requires you to perform the following tasks:

- Setting up initial communications
- Creating options files
- Setting up authentication
- Setting up message logging
- Initiating and monitoring the PPP connection

The following sections discuss these configuration tasks, and Section 6.2.3.6 describes additional steps you need to take if you are connecting to a Microsoft NT Remote Access Server (RAS).

6.2.3.1 Setting Up Initial Communications for a Dial-Out System

After you connect your modem to a serial port on your system, do the following:

1. Verify that you can communicate with the modem:
 - a. Edit the `/etc/remote` file and copy the `kdebug` entry.
 - b. Modify the new entry, providing a system name, the terminal device name (`tty00` or `tty01` depending on your system), the speed, and parity. See `remote(4)` for more information.
 - c. Use the `tip` command to access the modem as follows:

```
% tip system_name
```

The *system_name* is stored in the `/etc/remote` file.
 - d. If your modem is using the AT command language, enter the following command:

```
AT RETURN
```

If the modem is not in quiet mode, it responds with an OK message.
2. Contact the administrator of the remote system or your Internet Service Provider (ISP) and obtain the following information:
 - Your remote IP address and netmask, unless the remote system assigns the IP address dynamically
 - Characters that might need to be escaped
 - Instructions on how to log in and use the remote service

This information is used to create a `chat` script, which automates the dial-out process. A `chat` script is a file that contains a list of

commands that the `chat` program uses to direct the modem. It contains the number to dial and the information to send to the remote system to start the `pppd` daemon.

Note

You can use the `tip` command to dial out and log in to the remote system to collect additional information about the process. Write down the exact prompt, login sequence, and `pppd` start-up sequence for use in the `chat` script.

3. Create a `chat` script, as described in Section 6.2.1.1, to automate the dial-out process.

6.2.3.2 Creating Options Files for a Dial-Out System

Use the SysMan Menu of the Common Desktop Environment (CDE) Application Manager to create PPP options files. To invoke the SysMan Menu application, follow the instructions in Section 1.1.1.

To create an options file for a dial-out system, do the following:

1. From the SysMan Menu, select Networking→Additional Network Services→Serial Line Networking→Point-to-Point Protocol (PPP)→Create option files to display the PPP Option Files dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman ppp_options
```

2. Select a file from the list that is displayed and select Modify. Or, do the following to create a new options file:
 - a. Select the New File... option to display the Create PPP Options File dialog box.
 - b. Enter the new file name and select OK.

The Modify PPP Options File dialog box is displayed.

3. Select Dial-Out Options and select Configure to display the Dial-Out Options dialog box. Complete the fields using the information that you gathered on the PPP Setup Worksheet.

If your system is standalone and you are connecting to the Internet through the remote system, add a default route via the remote host. Under the System Routing Tables option, select the appropriate radio button.

See `pppd(8)` for a complete list of `pppd` options.

4. Select OK to close the Dial-Out Options dialog box.

5. Select **Advanced PPP Options** if you want to configure additional PPP options. Make the necessary changes, then select **OK** to close the associated dialog box.
6. Select **OK** in the **Modify PPP Options File** dialog box to save the changes and to close the dialog box.
7. Select **Exit** to close the **PPP Option Files** dialog box.

You can use the **SysMan Menu** utility to copy, modify, and delete option files. See the online help for more information.

6.2.3.3 Setting Up Authentication for a Dial-Out System

The `chap-secrets` and `pap-secrets` files contain entries that can be used for authentication purposes, as discussed in Section 6.2.1.3. The following sections describe how to create entries in these files.

6.2.3.3.1 Creating Entries in the PAP Secrets File

Use the **SysMan Menu** of the **Common Desktop Environment (CDE)** **Application Manager** to create entries in the `pap-secrets` file. To invoke the **SysMan Menu** application, follow the instructions in Section 1.1.1.

To create entries in the `pap-secrets` file, follow these steps:

1. From the **SysMan Menu**, select **Networking**→**Additional Network Services**→**Serial Line Networking**→**Point-to-Point Protocol (PPP)**→**Modify pap-secrets file** to display the **Modify pap-secrets File** dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman pap
```

2. Select **Add** to display the **Add pap-secrets Entry** dialog box. Supply the requested information.
3. Select **OK** to save the current changes and close the dialog box. The **Modify pap-secrets File** dialog box displays the new entry.
4. Repeat steps 2 and 3 as many times as necessary.
5. Select **Exit** to close the **Modify pap-secrets File** dialog box.

You can also use the **SysMan Menu** utility to modify or delete entries in the **PAP secrets** file. See the online help for more information.

6.2.3.3.2 Creating Entries in the CHAP Secrets File

Use the SysMan Menu of the Common Desktop Environment (CDE) Application Manager to create entries in the `chap-secrets` file. To invoke the SysMan Menu application, follow the instructions in Section 1.1.1.

To create entries in the `chap-secrets` file, follow these steps:

1. From the SysMan Menu, select **Networking**→**Additional Network Services**→**Serial Line Networking**→**Point-to-Point Protocol (PPP)**→**Modify chap-secrets file** to display the **Modify chap-secrets File** dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman chap
```

2. Select **Add** to display the **Add chap-secrets Entry** dialog box. Supply the requested information.
3. Select **OK** to save the current changes and close the dialog box. The **Modify chap-secrets File** dialog box displays the new entry.
4. Repeat steps 2 and 3 as many times as necessary.
5. Select **Exit** to close the **Modify chap-secrets File** dialog box.

You can also use the SysMan Menu utility to modify or delete entries in the CHAP secrets file. See the online help for more information.

6.2.3.4 Setting Up Message Logging

To set up message logging, complete the following steps:

1. Edit the `/etc/syslog.conf` file, as follows:

Note

Whitespace in the `/etc/syslog.conf` file must consist of tab characters. Spaces are not acceptable. See `syslogd(8)` for further information.

- a. Add the `local2` facility (used by the `pppd` daemon and the `chat` program) to the line that specifies `/dev/console` as the message destination, as follows:

```
kern.debug;local2.notice                               /dev/console
```

In this example, the `notice` severity level is specified. For more information about this severity level and logging system messages in general, see the *System Administration* guide.

- b. Add the following entry to the file to create a `ppp-log` file:

```
local2.debug                                /etc/ppp/ppp-log
```

- c. Save the edits and close the file.

2. Stop and restart the `syslogd` daemon by entering the following commands:

```
# /sbin/init.d/syslog stop
# /sbin/init.d/syslog start
```

6.2.3.5 Initiating and Monitoring a PPP Connection

Before initiating a PPP connection, note the following guidelines:

- Do not use the `ifconfig` command to configure the addresses of the `ppp` interface. The `pppd` daemon assigns addresses and identifies the interface as running.
- Whether you run `pppd` manually on the remote machine or use a script file on the local machine to run `pppd` on the remote machine, do not provide a device name to `pppd`; it uses the controlling `tty` by default.

Once you have configured your system for a PPP dial-out connection, initiate the connection as follows:

1. Invoke the `pppd` daemon on the local system to connect to the remote system. For example, the following command starts a link on `tty01` and specifies the `connect` option to run the `chat` program using the specified `chat` script file.

```
% pppd /dev/tty01 38400 connect 'chat -f /etc/ppp/chat-script'
```

2. Issue the following command to monitor the `ppp-log` file and to determine whether the PPP connection is active:

```
% tail -f /etc/ppp/ppp-log
```

If problems occur while using PPP, see Section 15.16.

6.2.3.6 Connecting to a Microsoft NT Remote Access Server

This section describes how to establish a dial-out connection from a Tru64 UNIX system to a Microsoft NT Remote Access Server (RAS).

You will need to supply the following information in the `/etc/ppp/chap-secrets` file:

- NT login name and password
- NT domain name

For details on creating the `/etc/ppp/chap-secrets` file, refer to Section 6.2.3.3.2 and the `pppd(8)` reference page.

6.2.3.6.1 Configuring an NT RAS Server

To configure a Tru64 UNIX system to allow dial-out access to an NT RAS server, do the following:

1. Log in as root.
2. Create an `/etc/ppp/chap-secrets` file. For example, if you are dialing into a server named `money` with a username of `monopoly` and a password of `candlestick`, create the `chap-secrets` file as follows:

```
#
# secret for logging into an NT RAS server
#
monopoly  money  candlestick
```

3. Issue the `pppd` command with the user and remote name arguments to select the secret for the server `money`. For example:

```
# pppd tty00 38400 username monopoly remotename money
```

If the RAS server you dial out to is not a standalone server or a domain controller, you might need to prepend your NT domain name to your username. To do this from the command line, enter a command similar to the following in which `empire` is the domain name:

```
# pppd tty00 38400 user 'empire\\monopoly' remotename money
```

Note

Single quotes are required in the previous example to escape the backslash characters.

Alternatively, you can place this information in the `/etc/ppp/chap-secrets` file as follows:

```
#
# secret for logging into an NT RAS server
#
empire\\monopoly  money  candlestick
```

You can also use the `chat` program to automate any dialog that is required to establish a dial-out connection. See Section 6.2.1.1 for information on using the `chat` program.

During authentication, Microsoft Windows does not send its node name to the PPP peer. The peer must know beforehand the node name of the Microsoft Windows system to select the correct secret from the `chap-secrets` file. You

can do this by setting the `remotename` option of the `pppd` daemon. If this is not done, authentication might fail and the PPP link will be disconnected.

6.2.3.6.2 Solving Microsoft CHAP Authentication Problems

Microsoft CHAP (MS-CHAP) returns error codes if authentication fails. To log the error messages, invoke the `pppd` command with the `debug` option. The error code format is as follows:

```
rcvd [CHAP Failure id=0x0 "E=NUM R=1"]
```

`NUM` is the error code that MS-CHAP returns.

Possible error codes include:

Error Code	Explanation
E=646	Your NT account has restricted log in hours. At this time of day you may not log on.
E=647	Your NT account has been disabled.
E=648	Your NT account password has expired. (Note that <code>pppd</code> cannot negotiate a change of password.)
E=649	You are not permitted to dial in.
E=691	The RAS server could not validate your username. You supplied an incorrect password, or you need to prepend your domain name to your username.

6.2.4 Configuring a Dial-In System with PPP

If the system will answer calls from remote systems, you must establish a dial-in connection, which requires you to perform the following tasks:

- Setting up initial communications
- Creating options files

The following sections discuss these configuration tasks.

6.2.4.1 Setting Up Initial Communications for a Dial-In System

To configure a dial-in system, complete the following steps after you connect your modem to a serial port:

1. Set up your modem for dial-in access. See Section 6.3.2 for more information.

2. Edit the `/etc/passwd` file and create a dedicated entry for a PPP user. For the login shell field, specify `/usr/sbin/startppp`, which starts the `pppd` daemon for dial-in connections. For example:

```
ppp1:password:10:20:Remote PPP User:/usr/users/guest:/usr/sbin/startppp
```

3. Edit the `/etc/inittab` file and create an entry for each terminal device that is to run PPP. For example:

```
modem:3:respawn:/usr/sbin/getty /dev/tty00 M38400 vt100
```

See `inittab(4)` for more information.

4. Issue the `init q` command to immediately start the `getty` process.
5. If the dial-in system will be a gateway for the dial-out system to reach other systems on the LAN, the dial-in system must be configured as an IP router and must run the `gated` daemon. Edit the `/etc/gated.conf` file and delete the `nobroadcast` option (if specified) in the `rip` statement. See Chapter 2 for basic network setup information and `gated.conf(4)` for `gated` options.

6.2.4.2 Creating Options Files for a Dial-In System

Use the SysMan Menu of the Common Desktop Environment (CDE) Application Manager to create PPP options files. To invoke the SysMan Menu application, follow the instructions in Section 1.1.1.

To create an options file for a dial-in system, do the following:

1. From the SysMan Menu, select Networking→Additional Network Services→Serial Line Networking→Point-to-Point Protocol (PPP)→Create option files to display the PPP Option Files dialog box. Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman ppp_options
```
2. Select a file from the list that is displayed and select Modify. Or, do the following to create a new options file:
 - a. Select the New File option to display the Create PPP Options File dialog box.
 - b. Enter the new file name and select OK.

The Modify PPP Options File dialog box is displayed.

3. Select Dial-In Options and select Configure to display the Dial-In Options dialog box. Complete the input fields using the information that you gathered on the PPP Setup Worksheet. By default, an entry is automatically added to the Address Resolution Protocol (ARP) table. If you do not want an entry to be added, set the appropriate radio button to the On position.

4. Select OK to close the Dial-In Options dialog box.
5. Select Advanced PPP Options if you want to configure additional PPP options. Make the necessary changes, then select OK to close the associated dialog box.
6. Select OK in the Modify PPP Options File dialog box to save the changes and to close the dialog box.
7. Select Exit to close the PPP Option Files dialog box.

You can also use the SysMan Menu utility to copy, modify, and delete option files. See the online help for more information.

6.2.5 Terminating PPP Connections

To terminate the PPP link, send a TERM or INTR signal to one of the `pppd` daemons by issuing the following command:

```
# kill `cat /etc/ppp/pppxx.pid`
```

In the previous command, `pppxx` specifies the `pppd` used for the PPP connection. The `pppd` specified in the command notifies other related `pppd` daemons to terminate (clean up and exit).

If `pppd` is connected to a hardware serial port connected to a modem, it will receive a HUP signal when the modem hangs up, which causes it to clean up and exit. This action depends on the driver and its current settings.

6.3 Guidelines for Using Modems

The operating system software enables you to use a variety of modems for point-to-point connections to systems that are not in close proximity to each other. These connections can be Serial Line Internet Protocol (SLIP), Point-to-Point Protocol (PPP), and UNIX-to-UNIX Copy Program (UUCP) connections. In addition, these connections can be basic dial-out/dial-in connections; for example, you can log in to a remote system to perform remote system administration.

This section presents general guidelines for using modems on Tru64 UNIX systems for all types of connections. See Section 6.1.2.1 for specific information on SLIP and PPP connections and see Chapter 11 for information about UUCP connections.

6.3.1 Using the Correct Modem Cables

You must use the correct cable to connect a modem to the serial port. Use of an incorrect cable might result in signal loss and associated software errors. Table 6-7 lists the cables you can use to connect modems. The cable connector is either 25-pin or 9-pin, depending on the type of serial port on

your system. See the hardware documentation for your system if you are uncertain about the type of serial port.

Note

DECconnect cables do not provide a sufficient number of wires for full modem control; do not use them.

Table 6-7: Types of Modem Cable

Cable Number	Description
BC22E-xx ^a	16-wire modem cable (male DB25 pin to female DB25 pin cable)
BC22F-xx ^a	25-wire modem cable (male DB25 pin to female DB25 pin cable)
BC29P-xx ^a	Male DB25 pin to female DB9 pin cable
PC modem cable	Male DB25 pin to female DB9 pin cable

^a xx denotes the cable length. For example, BC22E-10 is a ten-foot cable.

6.3.2 Configuring a System for Dial-In Access

After you obtain the correct cable and connect your modem to it and the telephone network, do the following:

1. Edit the `/etc/remote` file and create an entry similar to the `kdebug` entry. For example, if your modem is connected to the `tty00` port and you will use a speed of 38,400 bps to access the modem, create an entry similar to the following:

```
b38400:dv=/dev/tty00:br#38400:pa=none
```

Note

Some modems set their speed to the serial port rate. Be sure to access the modem using the same speed that you will specify to the `getty` or `uugetty` utility. Otherwise, you might not be able to log in because of the mismatch.

2. Use the `tip` command to access the modem as follows:

```
tip b38400
```

The `tip` utility responds with a `connected` message. You can now communicate with the modem.

3. If your modem uses the AT command set, a standard language for communication between terminals and modems, enter the following command to verify that the modem is ready and listening:

at `Return`

If the modem is not in quiet mode, it responds with an OK message.

4. Configure the modem for dial-in access as specified in Section 6.3.2.1.
5. Edit the `/etc/inittab` file and create an entry for the modem. If you want to use the modem line in nonshared mode, create an entry similar to the following:

```
modem:23:respawn:/usr/sbin/getty /dev/tty00 M38400 vt100
```

If you want to use the modem line in shared mode (for dial-out and dial-in connections), use the `uugetty` utility instead of the `getty` utility and create an entry similar to the following:

```
modem:23:respawn:/usr/lib/uucp/uugetty -r -t 60 tty00 38400
```

If you specify a speed greater than 9600 bps, you must edit the `/etc/uugettydefs` file and create an entry for the speed you want.

With the `uugetty` utility, you can use the `tip` and `cu` utilities, but differences in file locking might prevent the use of third-party utilities.

Note

If you want to use the `uugetty` utility, you must install the UNIX-to-UNIX Copy Facility subset.

6. As root, start the `getty` or `uugetty` process by entering the following command:

```
init q
```

The `getty` or `uugetty` process starts, then goes to sleep, waiting for someone to dial in to the system.

6.3.2.1 Setting Up a Modem for Dial-In Access

To configure your modem for dial-in access, you need to send various commands to the modem by using the AT command set. Table 6-8 lists the AT commands required. These command settings are generally the same as the default settings for most modems, but you can enter them again to verify that your modem is correctly configured.

Table 6–8: Modem Commands for Dial-In Access

Command	Description
at&c1	Normal Carrier Detect (CD) operation. Tells the modem not to raise Carrier Detect until it sees Carrier Detect from the other modem.
at&d2	Normal Data Terminal Ready (DTR) operation. This tells the modem to hang up the line when DTR drops. For example, when the user logs off the system.
atq1	Sets the modem to quiet mode. Result codes are not sent to the system.
ate0	Echo off. This prevents the modem from echoing the login prompt issued by the <code>getty</code> process.
ats0= <i>n</i>	Specifies the number of rings to wait before answering. If <i>n</i> = 0 (zero), the modem will not answer.
at&w0	Saves the current modem settings in NVRAM. Most modems contain user profiles where modem settings can be stored for future use. This command stores the settings in the default profile, 0.

You can enter these commands individually or as one command. For example:

```
at&c1&d2q1e0s0=n&w0 
```

Enter the following command to verify the results (these characters are not displayed on the screen because you turned echo off with the `e0` command):

```
at&v 
```

The active profile and stored profile 0 will reflect the values you entered. The active (or current) profile is lost when you turn the modem off, but the stored profile will preserve the modem settings for future use.

In addition to the specified settings, configure the type of flow control to use for the connection between the computer and the modem. The operating system supports both hardware and software flow control. If your computer supports hardware flow control, set the modem and the serial line to use hardware flow control by using the appropriate commands. If hardware flow control is not supported, use software flow control. See the manuals for your computer and your modem for more information.

6.3.3 Configuring Your System for Dial-Out Access

After you obtain the correct cable and connect your modem to it and the telephone network, do the following:

1. Verify that there is an entry for the modem specified with the `modemtype` subcommand in the `/etc/acucap` file. If an entry does not exist, do the following:
 - a. Copy an entry similar to that of your modem. The following entry is for a US Robotics modem for use in shared mode with `tip`:

```
us|US|US Robotics (28.8 fax/data modem):\
:cr:hu:ls:re:ss=AT\rATE1Q0&C0X0&A0\r:sr=OK:\
:sd#250000:di=ATD:dt\r:\
:dd#50000:fd#50:os=CONNECT:ds=\d+++ \dATZ\r\dATS0=2\r:\
:ab=\d+++ \dATZ\r\dATS0=2:
```

- b. Modify the modem attributes to match those of your modem and include the debug option (`db`). With debugging turned on, the modem will provide you with additional information with which to tune the modem attributes in the file. See `acucap(4)` for more information.
2. Create an entry in the `/etc/remote` file for the system you want to call, as specified in Section 6.3.3.1.
3. If you use the `getty` utility to provide access to the system from a modem and a `getty` process is already running, do the following:

- a. Edit the `/etc/inittab` file and change the Action field of the modem entry from `respawn` to `off` as follows:

```
modem:23:off:/usr/sbin/getty /dev/tty00 M38400 vt100
```

See `inittab(4)` for more information.

- b. Issue the `init q` command to terminate the `getty` process.
4. Use the `tip` command, specifying the `-baud_rate` flag and the telephone number to dial out as follows:

```
tip -38400 8881234
```

In this example, `tip` strips the minus sign (`-`) from the baud rate and concatenates the `tip` command name and the baud rate to create the string `tip38400`. Then, `tip` searches the `/etc/remote` file for the entry matching the string. The entry in the `/etc/remote` file points to the capability information in the `us38400` entry to initialize the modem.

You can specify the telephone number on the command line to share the same modem attributes for outgoing connections that have different telephone numbers.

When you log off the remote system and exit `tip`, the saved settings are restored and the modem is ready for the next user. If used in shared mode, the modem is available for dial-in access.

6.3.3.1 Creating Entries in the `/etc/remote` File

The `/etc/remote` file stores information about the dial-out connections that you establish.

You can use this file to supply the terminal device name, connection speed, and the `/etc/acucap` file that defines your modem. For example, the following two entries are for the modem specified in step 1a of Section 6.3.3:

```
tip38400:tc=us38400 [1]
us38400|38400 Baud dial out via US Robotics modem:\ [2]
      :el=^U^C^R^O^D^S^Q@:ie=#%$:oe=^D:\ [3]
      :dv=/dev/tty00:br#38400:ps=none:at=us:du: [4]
```

- [1] Points to the `us38400` entry specifying shared capabilities for modems
- [2] First line of the `us38400` entry
- [3] Defines end-of-line characters, and input and output end-of-file marks
- [4] Defines the device to open for the connection, the speed, the parity, the name of the `/etc/acucap` entry, and the dial-up line

You might use generic entries like these to connect to any number of remote systems.

Optionally, you can create an entry for each remote system you contact. Then you can include settings that are specific to those systems, for example, their phone numbers. See `remote(4)` for more information.

Local Area Transport Connections

The Local Area Transport (LAT) protocol supports communications between host computer systems and terminal servers with terminals, PCs, printers, modems and other devices over local area networks (LANs). The Tru64 UNIX LAT implementation is a STREAMS-based driver.

This chapter describes:

- The LAT implementation on Tru64 UNIX systems
- The different configurations possible in a LAT environment
- How to configure and maintain a LAT environment

For additional introductory information on LAT, see `lat_intro(7)`. For troubleshooting information, see Section 15.17.

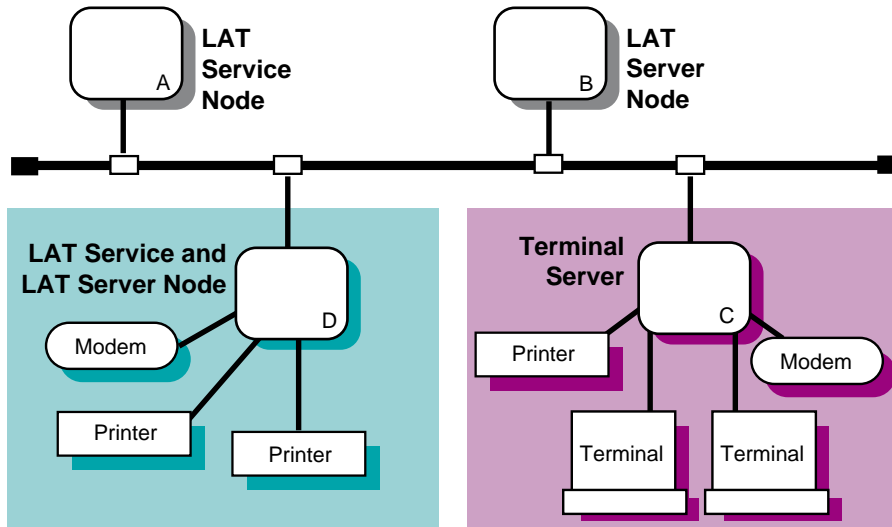

7.1 LAT Environment

In the LAT environment, systems can have the following roles:

- Service node — A system that offers LAT services to users on the LAN and accepts connections from server users.
- Server node — A terminal server or a system that is configured for outgoing connections. Server nodes enable users attached to the node to initiate LAT sessions through outgoing ports to LAT services offered by LAT service nodes.

Figure 7-1 shows a sample LAN with LAT server nodes and LAT service nodes.

Figure 7-1: Sample LAT Network Configuration

ZK-1179U-AI

The LAT software also permits host applications to initiate connections to server ports, designated as application ports, to access remote devices. The following sections describe:

- Types of LAT connections
- Access control in a LAT network
- Password specification for remote servers
- Load balancing

7.1.1 Types of LAT Connections

The following types of LAT connections are permitted:

- Terminal-to-host connections — The basic LAT connection in which a user at a terminal connected to a terminal server connects to a LAT service. For example, a user at a terminal connected to terminal server C and connecting to a service on host A in Figure 7-1 is using a terminal-to-host connection.
- Host-initiated connections — A connection in which a bit-serial, asynchronous device connected to a terminal server communicates with user-written applications on a LAT host. For example, a user who set up host A to use a printer on host D in Figure 7-1 is using a host-initiated connection.
- Outgoing connections — A connection in which a user on a LAT server node can connect to a LAT service by using the `llogin` command. For

example, a user on host B who connects to a LAT service on host A in Figure 7-1 is using an outgoing connection.

- Lattelnets gateway connections — A connection in which a user at a terminal connected to a terminal server connects to a remote host through an intermediate Tru64 UNIX host. For example, a user at a terminal connected to terminal server C who is connecting to the lattelnets service on host D in Figure 7-1 is using a lattelnets connection.

7.1.2 Controlling Access in a LAT Network

Because LAT networks are local in nature, you have a high degree of control over the LAT environment and who has physical access to LAT devices. In addition to controlling physical access, the following features enable you to control LAT access:

- LAT terminal server login password — You can require that users enter a password to gain access to terminal servers. (Refer to your terminal server documentation for more information.)
- LAT groups — You can establish LAT groups and restrict host communication to particular groups in the following cases:
 - On a LAT service node, by issuing a `latcp -g -a` command
 - On a LAT server node, by issuing a `latcp -u` command
 - On a terminal server (refer to your terminal server documentation for more information)

In general, groups are set up by the network manager, system manager, and server managers to partition the LAT network into logical subdivisions and to restrict message traffic between servers and service nodes. In addition, using groups can help you manage the size of the servers' LAT databases by limiting the number of service nodes for which the server keeps information.

Note

You can use groups to restrict access, but they are not intended as a security mechanism.

To establish a connection with a LAT service node, the group enabled on a terminal server port or an outgoing port on a LAT server node must match at least one group on the service node. Similarly, for a terminal server or server node to process messages from service nodes, the group enabled on a terminal server port or an outgoing port on the server node must match at least one group on the service node. Otherwise, the messages from the service nodes are ignored.

For more information on enabling LAT service node groups and outgoing port groups, refer to `latcp(8)`.

7.1.3 Specifying Passwords for Remote Services

The LAT protocol enables you to specify a password for access to remote services that are protected by a password. When password checking is enabled on a terminal server that offers a service that is password protected, you must specify the password when you map the application port; if you do not, all attempts to connect to the service from the terminal server are rejected. See `latcp(8)` for more information.

7.1.4 Load Balancing

When more than one node on a LAN offers the same service, the terminal server connects to the node with the highest rating for the service desired. The rating is based on the current load on the nodes that offer the service. This process is called load balancing.

Load balancing works in a heterogeneous environment. Therefore, service nodes with the same names may be running different operating systems.

7.2 Planning LAT

This section describes the tasks you must complete before configuring LAT.

7.2.1 Verifying That the LAT Subset Is Installed

Verify that the LAT subset is installed by entering the following command:

```
# setld -i | grep OSFLAT
```

If the LAT subset is not installed, install it by using the `setld` command. For more information on installing subsets see `setld(8)`, the *Installation Guide*, or the *System Administration* manual.

After the LAT subset is installed, reboot the system to load the LAT module into the kernel. The system is configured to dynamically load the LAT module into the kernel when the system boots.

7.2.2 Verifying DLB Support in the Kernel

After you install the LAT subset, verify that Data Link Bridge (DLB) support is in the kernel by issuing the following command:

```
# sysconfig -q dlb
```

If the `dlb:` prompt is not displayed, log in as superuser and complete the following steps:

1. Edit the configuration file and add the following entry to it:

```
options DLB
```

The default configuration file is `/sys/conf/HOSTNAME` where `HOSTNAME` is the name of your host processor, in uppercase letters.

2. Build a new kernel by issuing the `doconfig` command. If you are unfamiliar with rebuilding the kernel, see the *System Administration* manual.
3. Reboot your system with the new kernel by issuing the following command:

```
# shutdown -r now
```

This command immediately shuts down and automatically reboots the system.

7.2.3 Preparing for the Configuration

After you verify DLB support in the kernel, you can configure LAT by using the `latsetup` utility.

Figure 7–2 shows the LAT Setup Worksheet, which you can use to record the information required to configure LAT. If you are viewing this manual online, you can use the print feature to print the worksheet. The following sections explain the information you need to record on the worksheet.

Figure 7–2: LAT Setup Worksheet

LAT Setup Worksheet	
Start LAT automatically at boot time:	Yes <input type="checkbox"/> No <input type="checkbox"/>
Type of tty devices:	_____
Number of LAT tty devices:	_____
Number of LAT entries (getty) in /etc/inittab:	_____

Start LAT automatically at boot time

By default, the `/sbin/init.d/lat` startup and shutdown script automatically starts LAT upon reaching run level 3 and stops LAT when exiting run level 3. If you do not want LAT to be started automatically, check No; otherwise, check Yes.

Type of tty devices

The type of terminal device (tty) for each LAT connection. Tru64 UNIX supports SVR4 and BSD device types. It is best to use SVR4 devices because the SVR4 format allows you to create more devices.

SVR4 device special files have the following format:

```
/dev/lat/n
```

The value *n* is a number between 620 and 4370. For example, /dev/lat/620, /dev/lat/777, and /dev/lat/4000 specify SVR4 devices.

BSD device special files have the following format:

```
/dev/ttyWX
```

The value *w* is a number from 0 to 9; *x* is an alphanumeric from 0 to 9, a lowercase a to z, or an uppercase A to Z. For example, /dev/tty02, /dev/tty0e, and /dev/tty9f specify BSD LAT terminal devices. However, all BSD terminal device names are not case sensitive. The device special files /dev/tty9f and /dev/tty9F are both converted to TTY9F.

This format enables you to specify up to 620 BSD terminal devices which are available to any serial devices (such as UUCP) running on the system. Therefore, fewer than 620 BSD devices may be available for LAT.

Number of LAT tty devices

The total of the desired number of simultaneous incoming LAT connections, the number of application ports, and the number of outgoing connections needed.

Number of LAT entries (getty) in /etc/inittab

The number of LAT `getty` entries to be added to the `/etc/inittab` file. This is the number of simultaneous incoming LAT connections desired.

7.3 Configuring LAT

Use the `latsetup` utility to configure and administer LAT on your system. To use the `latsetup` utility, LAT and DLB must be configured into the running kernel, your system must be at run level 3 or 4, and you must be logged in as superuser. See the `latsetup(8)` reference page for more information.

The `latsetup` utility allows you to do the following:

- Create LAT device special files.
- Add or remove `getty` entries to or from the `/etc/inittab` file.
- Execute the `init q` command.
- Start or stop the LAT driver.
- Enable or disable LAT automatic startup and shutdown. When enabled, LAT starts automatically upon reaching run level 3.

You cannot configure LAT over NetRAIN virtual interfaces or the adapters that compose NetRAIN sets. LAT is not supported over NetRAIN.

From the SysMan Menu, invoke the `latsetup` utility by selecting Networking→Additional Network Services→Configure Local Area Transport (LAT). Alternatively, enter the following command on the command line:

```
# /usr/sbin/latsetup
```

If your terminal does not support `curses`, you must specify the `-nocurses` flag. This flag allows you to run `latsetup` in command-line mode.

Note

Do not run multiple `latsetup` processes concurrently on the same machine. The `latsetup` user might receive erroneous information and the `/etc/inittab` file might become corrupted.

7.4 Starting and Stopping LAT

To manually start LAT, enter the following command:

```
# /sbin/init.d/lat start
```

To manually stop LAT, enter the following command:

```
# /sbin/init.d/lat stop
```

Note that when you stop LAT from within a LAT session, the session will close.

7.5 Creating a LAT Startup File

If LAT automatic startup and shutdown are enabled, when the system reaches run level 3, it loads LAT into the kernel and executes the `/sbin/init.d/lat` script. This script reads and executes the `latcp` commands in the `/etc/latstartup.conf` file (if this file exists), then starts LAT. See `latcp(8)` for more information on the `latcp` command.

If you do not have an `/etc/latstartup.conf` file, LAT is started with the default values for its parameters. Table 7-1 lists the LAT parameters and their default values.

Table 7-1: LAT Parameters

Parameter	Default Value								
Node name	Host name								
Multicast timer	60 seconds								
Network adapter	All network adapters connected to broadcast media, except for NetRAIN virtual interfaces (<code>nr</code>) and those adapters that compose NetRAIN sets.								
Service name	From the LAT node name parameter. Each service has the following parameters:								
	<table border="1"> <thead> <tr> <th>Parameter</th> <th>Default Value</th> </tr> </thead> <tbody> <tr> <td>Service description</td> <td>"Compaq Tru64 UNIX Version <i>x.x</i> LAT SERVICE"</td> </tr> <tr> <td>Rating</td> <td>Dynamic</td> </tr> <tr> <td>Group code</td> <td>0</td> </tr> </tbody> </table>	Parameter	Default Value	Service description	"Compaq Tru64 UNIX Version <i>x.x</i> LAT SERVICE"	Rating	Dynamic	Group code	0
Parameter	Default Value								
Service description	"Compaq Tru64 UNIX Version <i>x.x</i> LAT SERVICE"								
Rating	Dynamic								
Group code	0								
Agent status	Disabled								
Outgoing port groups	Group 0								
Maximum number of learned services	100								

If you want to customize LAT on your system, you can create and modify the `/etc/latstartup.conf` file to include `latcp` commands. For example, you can define a particular node name or add service names.

Note

If your system is a member of a cluster, you must create the `/etc/latstartup.conf` file as a Context-Dependent Symbolic Link (CDSL). See the *System Administration* manual for more information.

Example 7-1 shows a sample `/etc/latstartup.conf` file.

Example 7-1: Sample `/etc/latstartup.conf` File

```

/usr/sbin/latcp -n testnode 1
/usr/sbin/latcp -A -a lattelnet14 -i "LAT/telnet" -o 2
/usr/sbin/latcp -A -a testservice 3
/usr/sbin/latcp -g 0,21,52 -a testservice 4
/usr/sbin/latcp -A -a boundservice -p 620,621 5
/usr/sbin/latcp -c200 6

```

Example 7–1: Sample /etc/latstartup.conf File (cont.)

```
/usr/sbin/latcp -A -p 630 -O -V finance [7]
/usr/sbin/latcp -u 0,1,41,97 [8]
/usr/sbin/latcp -e ln0 [9]
```

- [1] Changes the LAT node name.
- [2] Adds an optional service that can be used for LAT/Telnet connections. (See Section 7.11 for more information on the LAT/Telnet gateway.)
- [3] Adds an unbound interactive `testservice` service.
- [4] Adds groups 0, 21, and 52 to the `testservice` service.
- [5] Adds a bound service and binds to it two LAT devices: 620 and 621, which are SVR4-style LAT devices.
- [6] Increases the number of learned services to 200.
- [7] Maps an outgoing port to `finance` service.
- [8] Adds outgoing port groups 0, 1, 41, and 97.
- [9] Adds the `ln0` adapter.

A `latcp` command that adds a service must occur in the `latstartup.conf` file before you can issue a `latcp` command requiring the service name. Lines 3 and 4 in Example 7–1 illustrate this point.

7.6 Customizing the inittab File

You can modify the `/etc/inittab` file to use a program other than `getty`. For example, you can add the following entry to `/etc/inittab` to configure LAT device 620 to use the user-defined program `myownprogram`:

```
lat620:34:respawn:/usr/sbin/myownprogram /dev/lat/620
```

The previous example uses an absolute pathname for the device `/dev/lat/620`.

For more information on using user-defined programs with LAT, see Section 7.12. For more information on the `/etc/inittab` file and the `getty` utility, see `inittab(4)` and `getty(8)`.

You can also modify the `/etc/inittab` file to add LAT devices created manually after the initial configuration by adding an entry similar to the following:

```
lat621:34:respawn:/usr/sbin/getty lat/621 console vt100
```

The second field (34) specifies the run level in which the entries will be processed. In this example, the `getty` process is spawned at either run level 3 or 4. In addition, this example uses a relative pathname, `lat/621`.

7.7 Running LAT Over Specific Network Adapters

If your system is configured with multiple network adapters, by default the `latcp` program attempts to start the LAT protocol on all adapters that can support it (which excludes NetRAIN virtual interfaces and the adapters that compose NetRAIN sets). For adapters connected to different logical networks, this is probably desirable. However, for adapters connected to a single logical network, it is recommended that you run the LAT protocol over only one adapter. To specify the adapter, add the `latcp -e adapter` command to the `/etc/latstartup.conf` file. See `latcp(8)` for more information.

Use the `netstat -i` command to determine the adapters defined on your system.

7.8 Setting Up Printers

The following sections describe how you can set up a printer to print through LAT by completing these tasks:

- Setting up the printer on a terminal server
- Testing the port configuration
- Setting up a service node for the printer
- Setting up the print spooler on the service node
- Testing the Printer

Once the printer is properly configured, local LAT hosts can access the printer through host-initiated connections, as described in Section 7.9.

These sections provide information on how to establish the LAT service. They do not contain all of the details of printer setup. For more information on setting up printers, see the *System Administration* manual, `printconfig(8)`, `lprsetup.dat(4)`, and `lprsetup(8)`.

In addition, before you start, you need to collect the following information:

- The name of the terminal server to which the printer will be attached
- Either or both of the following:
 - The name of the port to which the printer will be attached
 - The name of the service assigned for the remote printer
- Terminal server documentation

- Printer documentation

Note

The examples in this section use the DECserver 700 server. Please refer to the documentation supplied for your terminal server.

7.8.1 Setting Up the Printer on a Terminal Server

To set up a printer, do the following:

1. Connect the printer to a serial interface on a terminal server.
2. Use the terminal server commands specified in the terminal server documentation to set up the server to allow access to the attached remote printer through host-initiated requests from the service node. (Service node refers to the local Tru64 UNIX LAT host.)
3. Use the printer documentation to determine your printer's character size, flow control, parity, and speed.
4. Compare the printer's characteristics to the terminal server's port settings. You can display the settings on the terminal server console by entering a command similar to the following:

```
Local> SHOW PORT 7 CHARACTERISTICS
```

This command displays the characteristics for port 7. Minimally, the terminal server should have settings for the port similar to the following:

Character Size:	Printer's character size
Flow Control:	XON (or -CTS/RTS, for some printers)
Speed:	Printer's speed
Access:	Remote
Autobaud:	Disabled
Autoconnect:	Disabled

If the terminal server's port settings do not match the printer's characteristics, define the terminal server's port settings by using the `DEFINE` command. For example:

```
Local> DEFINE PORT 7 SPEED 9600
```

5. After you define the settings for the port, log out of that port to initialize the new settings. For example:

```
Local> LOGOUT PORT 7
```

7.8.2 Testing the Port Configuration

To verify that the printer characteristics match in the printer and in the terminal server port, use the `TEST PORT` command on the terminal server. For example, if the configuration is correct, the following command run on a DECserver 700 prints a test pattern of characters on a printer attached to port 7:

```
Local> TEST PORT 7
```

The printer prints 24 lines of test data unless you press the Break key at the terminal server console. If data does not print or if it is incorrect, the port or the printer is incorrectly set, or there is a hardware problem.

7.8.3 Setting Up a Service Node for the Printer

On the service node (local LAT host), use the `latcp` command to map an unused application port with the remote port or remote service on the terminal server. Use the terminal server name and either the name of the port or the name of the service for the printer from Section 7.8.1.

For example, the following command maps the local application port 621 for the server `LOC SER` to the remote printer port `port07`.

```
# latcp -A -p 621 -H LOC SER -R port07
```

The following command specifies the remote printer service name instead of the remote print port:

```
# latcp -A -p 621 -H LOC SER -V REMprinter07
```

For more information, see `latcp(8)`.

7.8.4 Setting Up the Print Spooler on the Service Node

To set up the print spooler for the remote printer, use the `lprsetup` command. The following symbols must be set in the `printcap` file for the service node (local LAT host) to access the remote printer through host-initiated connections:

- `ct` — Connection type
- `lp` — Device name to open for output

The following example shows an `/etc/printcap` entry for a LAT printer:

```
lp25|lp0:\
:af=/usr/adm/lpacct:\
:ct=LAT:\ 1
:lf=/usr/adm/lperr:\
:lp=/dev/lat/621:\ 2
:mx#0:\
```

```
:of=/usr/sbin/lpf:\
:sd=/usr/spool/lpd:
```

- ❶ Specifies LAT for the `ct` symbol.
- ❷ Specifies the LAT application port (tty device) that was used in the `latcp` command to set up the service node. You must specify the full path name for the `lp` symbol.

7.8.5 Testing the Printer

After you set up the printer, print a file to ensure everything works properly. For example, if the printer name is `lp25` and `test` is a text file, you can test the printer by issuing the following command:

```
# lpr -Plp25 test
```

If the printer does not work, verify that all the settings are correct. If the `printcap` file entry has an `lf` symbol defined, you can check the corresponding log file for error information.

7.9 Setting Up Host-Initiated Connections

A host-initiated connection is one in which any bit-serial, asynchronous device connected to a terminal server can communicate with user-developed applications on an appropriately configured system. Examples of such devices are terminals, modems, communications ports on other host computer systems, and printers. Printer connections are discussed in Section 7.8.

This section describes how you set up a system for host-initiated connections and provides guidelines for developing applications to take advantage of these connections.

7.9.1 Setting Up the System for Host-Initiated Connections

To set up your system for LAT host-initiated connections, do the following:

1. Use the `latcp -A -p` command to map an application port (tty device) on the system with a remote port or service on a terminal server. In the following example, 623 is the application port, T1301A is the terminal server name, and `PORT_6` is the terminal port name.

```
# /usr/sbin/latcp -A -p 623 -HT1301A -R PORT_6
```

Alternatively, you can specify a service name instead of a port name in this example.

2. Make sure the protection bits, the owner, and the group of the tty device are set appropriately for the intended use of the connection. If ordinary users will open and read the tty device, make the device world readable.
3. Set up the server port characteristics to match the characteristics of the device connected to the port and to allow host-initiated connections. See your device and terminal server documentation for this information.

7.9.2 Program Interface

Applications that employ host-initiated connections are much like applications for any tty device, with the following exceptions:

- The programs communicate with the LAT driver through the device special file. When the host program issues an `open` call on the LAT tty device, the LAT driver attempts to establish a connection to the target port or service on the target server. The driver reports success and failure codes in the `errno` variable.
- When the `open` call is successful, the user program issues `read` and `write` system calls to handle data transfers, and normal `ioctl` processing for the device control information.
- A `close` system call on the device terminates the LAT connection.

The `dial.c` application program in the `/usr/examples/lat` directory is an example of a program that can be used with host-initiated connections. To access this example, you must install the `OSFEXAMPLES` optional subset.

The Tru64 UNIX LAT implementation is a STREAMS-based tty design. When a LAT tty device is opened, the POSIX line discipline module `ldterm` is pushed onto the stream above the LAT driver. If your application does not need the additional processing provided by `ldterm`, it must remove the module from the stream.

The `lined.c` application program in the `/usr/examples/lat` directory demonstrates how terminal (tty) line disciplines are changed in a Clist-based tty and a STREAMS tty environment. To access this example, you must install the `OSFEXAMPLES` optional subset. Additionally, you can use the `strchg` command to change the STREAMS configuration of the user's standard input.

For more information, see `autopush(8)` and `strchg(1)`.

7.10 Setting Up Outgoing Connections

An outgoing connection is one in which a local user can connect to a service on a remote host by using the `llogin` command. To accomplish this, a named service on the remote host is associated with a terminal device special

file on the local host. See `llogin(1)` and the *Command and Shell User's Guide* for information on the `llogin` command.

7.10.1 Setting Up the System for Outgoing Connections

To set up your system for LAT outgoing connections, do the following:

1. Map an outgoing port (tty device) on the system with a port or service on a remote system by using the `latcp -A -p` command. In the following example, 621 is the outgoing port and `REMOTE_SERVICE` is the service name on the remote node:

```
# /usr/sbin/latcp -A -p 621 -O -V REMOTE_SERVICE
```

Alternatively, you can specify a remote node name and a port name, as in this example, where `titan` is the node and `PORT_1` is the port:

```
# /usr/sbin/latcp -A -p 621 -O -H titan -R PORT_1
```

2. Verify that the remote service is a learned service available to your system, by using the following command:

```
# /usr/sbin/latcp -d -l
```

If the service is not displayed, the maximum number of learned services has been reached; the service might still be available. When an outgoing connection is attempted, the local host determines whether the remote service is available. If it is available, the outgoing LAT connection is made.

To increase the maximum number of learned services, use the `latcp -c` command. See `latcp8` and `lat_intro(7)` for more information on learned services.

7.10.2 Program Interface

Applications developed to employ outgoing connections adhere to the same guidelines as applications developed for host-initiated connections. See Section 7.9.2 for more information.

The `getdate.c` application program in the `/usr/examples/lat` directory is as an example of a program that can be used with outgoing connections. To access this example, you must install the `OSFEXAMPLES` optional subset.

7.11 Setting Up the LAT/Telnet Gateway

The LAT/Telnet gateway service enables a user on a LAT terminal server to connect to remote hosts running the Telnet protocol through an intermediate Tru64 UNIX host. The user does not have to log in to the local Tru64 UNIX system first. Optionally, if configured, you can use the `rlogin` command to connect directly to remote hosts.

To set up the LAT/Telnet gateway, perform the following steps:

1. Define the LAT/Telnet service by using the `latcp` command. For example:

```
# /usr/sbin/latcp -A -a lattelnet -i "LAT/telnet gateway" -o
```

The `-o` flag specifies that this is an optional service. Optional services are used with specialized applications that are written especially for LAT. These services are bound to LAT tty devices for the exclusive use of the specialized applications.

2. Edit the `/etc/inittab` file and modify the LAT device entries that you want to spawn the `lattelnet` service you created in step 1. The LAT terminals you select are dedicated to the gateway. The number of terminals selected determines the maximum number of simultaneous LAT/Telnet gateway sessions the system can deliver. For example, the following example shows LAT/Telnet gateway entries for three devices, which means that this system can deliver 3 simultaneous sessions:

```
lat624:34:respawn:/usr/sbin/lattelnet lat/624 lattelnet
lat625:34:respawn:/usr/sbin/lattelnet lat/625 lattelnet
lat626:34:respawn:/usr/sbin/lattelnet lat/626 lattelnet
```

If you want to use the `rlogin` command instead of Telnet, specify `/usr/bin/rlogin` as the third argument to the `lattelnet` program in the `/etc/inittab` entry. For example:

```
lat624:34:respawn:/usr/sbin/lattelnet lat/624 lattelnet /usr/bin/rlogin
```

3. Use the `init` program to read the `inittab` file and start the gateway by using the `init q` command.
4. Verify that the `lattelnet` process has started by using the `ps` command.

The `lattelnet` program uses the `syslogd` daemon to log messages to the `/var/adm/syslog.dated/date/daemon.log` file. Check this file to verify that no error messages were generated.

5. Connect to the gateway from the LAT terminal server by entering the `CONNECT` command. For example, to connect to a remote node named `REMOTE` by using a local node named `LOCAL` as a gateway, enter:

```
Local> CONNECT LATTELNET NODE LOCAL DEST REMOTE
```

You can use this command line for either Telnet or `rlogin`.

Alternatively, if connecting for Telnet, you can enter the service name `LATTELNET` and wait to be prompted for the remote node desired. The following example shows what occurs when a user on a terminal server connects to the service `LATTELNET` and waits for a login prompt from remote node `MYTRIX`:

```

Local> CONNECT LATTELNET
LAT to TELNET gateway on printf
telnet> OPEN MYTRIX
Trying...
Connected to mytrix.
Escape character is '^]'.
mytrix login:

```

7.12 Creating Dedicated or Optional Services

Dedicated services can be used in combination with your own specialized applications. The following specialized application programs are provided in the `/usr/examples/lat` directory:

- `latdate.c` — Provides a user with the date and time
- `latdlogin.c` — Provides a LAT/DECnet gateway for logging in over DECnet

Setting up a dedicated service is similar to setting up the LAT/Telnet gateway. (See Section 7.11.) To set up a dedicated service, complete the following steps:

1. Log in as root.
2. After you enter and compile the application code, copy the executable to the directory of your choice.
3. Add the service by using the `latcp -A -a` command. For example:

```
# /usr/sbin/latcp -A -a showdate -i "LAT/date service" -o
```

The `-o` specifies that this is a dedicated service.

4. Edit the `/etc/inittab` file and add the dedicated tty device entries. For example:

```
lat630:3:respawn:/usr/sbin/latdate lat/630 showdate
```

Note

You need an entry in the `/etc/inittab` file for every simultaneous service you want to run. The previous example only allows for one user of the `latdate` service at any one time.

5. Use the `init` program to read the `inittab` file and start the service by using the `init q` command.

To use the service at a LAT terminal, issue the `CONNECT` command. For example:

```
Local> CONNECT SHOWDATE
```

A Tru64 UNIX host can also offer bound interactive and unbound interactive services. See `lat_intro(7)` for more information. For information on the commands used to create these services, see `latcp(8)`.

7.13 Providing a Dedicated tty Device on a Terminal

A terminal connected to a terminal server port can offer a dedicated tty device on a given Tru64 UNIX LAT host. This configuration is useful when the terminal user needs access to a specific application (for example, a database) on the host, but must not be allowed to access other applications or hosts for security reasons.

Once configured, the terminal will always be connected to the specified tty device on the LAT host. The user at the terminal cannot switch sessions or connect to different hosts or different tty devices on that host.

7.13.1 Setting Up a Dedicated tty Device

To set up a dedicated tty device on a terminal, perform the following steps:

1. Determine the name of the terminal server and the port name on which the terminal is connected. The following terminal server commands display the name of the server and the port name, respectively:

```
Local> SHOW SERVER  
Local> SHOW PORT number
```

The *number* variable is the number of the port on the terminal server.

2. On the LAT host, map an application port (tty device) to the port on the terminal server by using the `latcp -A -p` command. For example, the following command maps an SVR4 device (application port 630 to port 2 on the terminal server LATTERM):

```
# latcp -A -p630 -H LATTERM -R PORT_2
```

For more information, see `latcp(8)`.

3. On the LAT host, add a `getty` entry to the `/etc/inittab` file for the tty device that was mapped as an application port. For example:

```
lat630:34:respawn:/usr/sbin/getty lat/630 console vt100
```

4. On the terminal server, define the port's access to be `REMOTE` and log out from the port. For example:

```
Local> DEFINE PORT 2 ACCESS REMOTE  
Local> LOGOUT PORT 2
```

5. Press Return on the terminal connected to the terminal server port that you just set up. When the system prompt is displayed, the terminal is connected to the dedicated tty device.

If you need to repeat the procedure, remove the `getty` entry from the `/etc/inittab` file, issue the `init q` command, and start the procedure from the beginning.

7.13.2 Removing a Dedicated tty Device

To remove a dedicated tty device from a terminal port and allow the terminal connected to the port to connect to any host, do the following:

1. Log in to another terminal on the same server.
2. Set the port's access to LOCAL and log out from the port. For example:

```
Local> DEFINE PORT 2 ACCESS LOCAL  
Local> LOGOUT PORT 2
```

3. Unmap the application port and remove the `getty` entry from the `/etc/inittab` file.

Domain Name System

The Domain Name System (DNS) is a mechanism for resolving unknown host names and Internet Protocol (IP) addresses that originate from sites on your company's intranet or the Internet. A database lookup service that is part of the DNS daemon searches for the unknown hosts in local and remote `hosts` databases, which are distributed networkwide by the DNS.

The implementation of DNS in Tru64 UNIX is based on Version 8.2.2 of the Berkeley Internet Name Domain (BIND) service, which is maintained by the Internet Software Consortium.

This chapter describes:

- The DNS environment
- How to configure your system for DNS
- How to manage DNS servers and clients

For introductory information on DNS, see `bind_intro(7)`. For additional information about BIND service, see Appendix H and the *BIND Configuration File Guide* (provided in HTML format on the Tru64 UNIX Documentation CD-ROM). You can also visit the Internet Software Consortium website at the following URL:

<http://www.isc.org>

For IPv6 environments, the BIND server daemon, `/usr/sbin/named`, supports AAAA lookups over IPv4 (AF_INET) connections only. The resolver and server have not been ported to IPv6, but IPv6 applications can make `getaddrinfo` and `getnameinfo` calls to retrieve the AAAA records. See the *Network Programmer's Guide* for information on using these routines.

For troubleshooting information, see Section 15.7 and Chapter 17 for servers and Section 15.8 for clients.

8.1 DNS Environment

In the DNS environment, systems can have the following roles:

- Master server — A system that is an authoritative source for information about a zone or zones and that maintains the master copy of the DNS database for the zone or zones.

This system runs the `named` daemon, answers requests from clients and other servers, caches information, and distributes the databases to slave servers.

- Slave server — A system that is an authoritative source for information about a zone or zones, but does not maintain the master copy of the DNS database for the zone or zones. Instead, a slave server loads its database files from the master server when the master server indicates that the files have been updated.

This system runs the `named` daemon, provides backup for the master server, answers requests from clients and other servers, and caches information.

- Stub server — A master server that delegates authority for a specified subzone to a server local to the subzone.

The stub server does not retain information in its configuration files about the machines in the specified subzone. Instead of searching the master DNS database, it queries the local server for information about machines in the subzone.

Typically, stub service is implemented so that the administrator of a subzone can change the configuration of the subzone without affecting the configuration file on the master server.

- Caching-only server — A system that is not authoritative for any zones. This system runs the `named` daemon and responds to queries from other servers and clients by querying other servers for the information and caching the information it receives. Information is stored until the data expires.

Typically, a caching-only server has direct access to the Internet and it answers queries exclusively about sites on the Internet.

- Forward-only server — A system that might be an authoritative source for information about a zone or zones, but is restricted as to how it obtains information about zones for which it is not authoritative.

This system runs the `named` daemon and responds to queries from other servers and clients with information from its authoritative data and cache data. If the information is not present, the system forwards queries to a list of systems specified as forwarders in its `named.conf` file. The queries are forwarded to each forwarder system until the list is exhausted or the query is satisfied. Forward-only servers store the information they receive until the data expires.

Typically, a forward-only server has restricted access to an intranet or the Internet. By providing a list of specific forwarders to contact, an administrator can prevent a forward-only server from attempting to contact servers that it cannot access.

- **Client** — A system that queries a server for host name and address information, interprets responses, and passes information to requesting applications. The client is also called a resolver. A client does not run the `named` daemon.

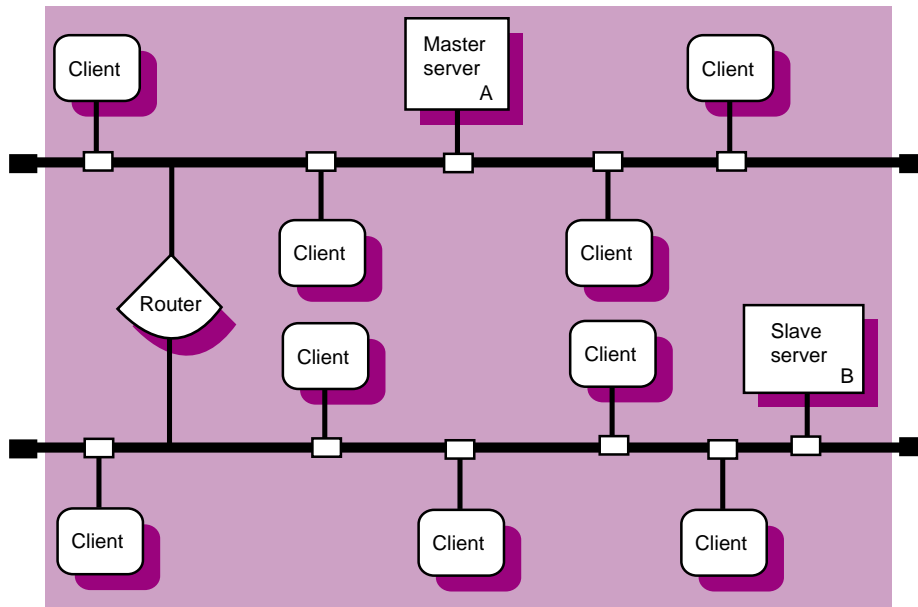

Note

Documentation for BIND prior to Version 8.1.1 referred to the master server as a primary server and the slave server as a secondary server. Though the terminology has changed, master and slave servers are still referred to as having primary and secondary authority, respectively, for zones.

DNS runs on each system in your network. You must decide what role each system will play in the DNS environment that you create. For each domain, select one host to be the master server; there can be only one master server for each domain. Select one or more hosts to be slave, stub, and caching-only servers. Configure the rest of the hosts as DNS clients.

Figure 8-1 shows a domain in which there are two servers, one on each subnet, and multiple clients. Server A, the master server, has primary authority for the zone and maintains the database files for the zone. Server B, the slave server, has secondary authority for the zone; it obtains a copy of the zone database from Server A and responds to queries from clients.

Figure 8–1: Sample Small DNS Configuration

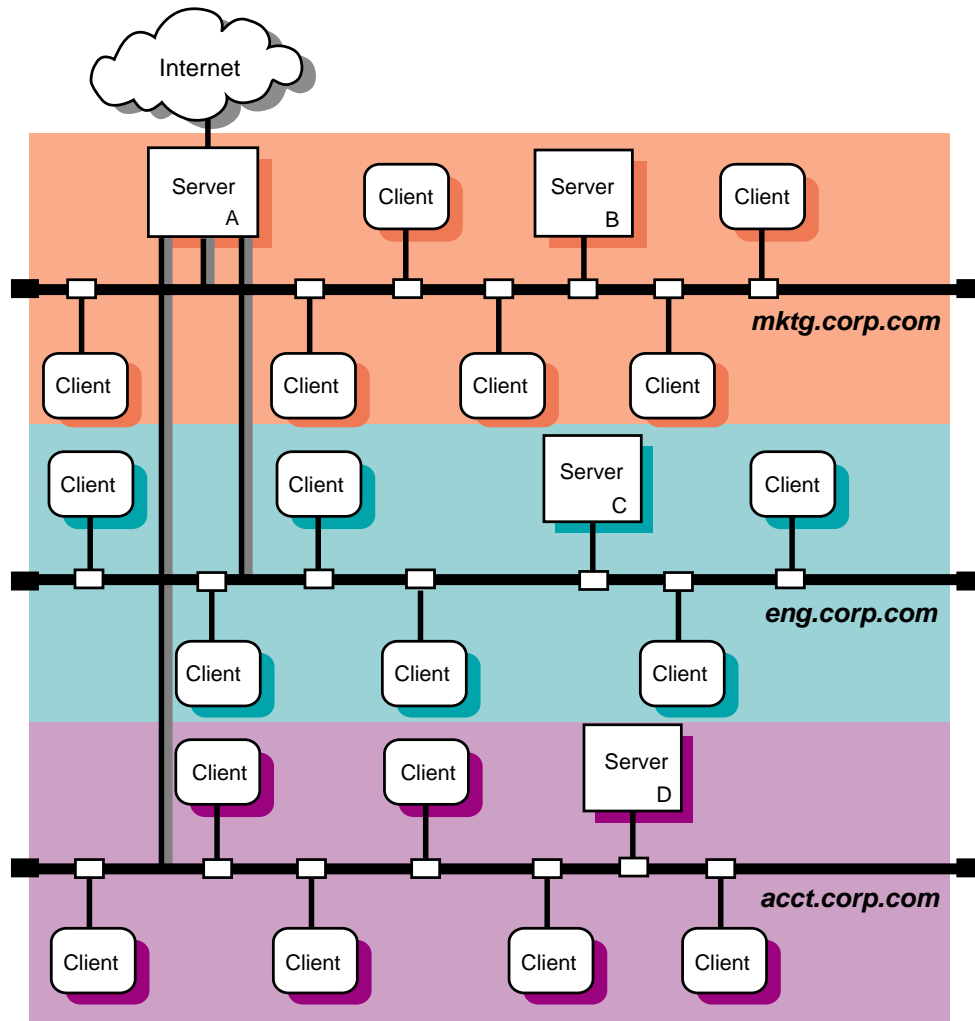

ZK-1162U-AI

Figure 8–2 shows a domain in which there are three zones: `mktg.corp.com`, `eng.corp.com`, and `acct.corp.com`. Server B is the master server for the `mktg.corp.com` zone and a slave server for the other two zones. It has primary authority for `mktg.corp.com` and secondary authority for each of the other two zones. Server C has primary authority for the `eng.corp.com` zone and secondary authority for each of the other two zones. Server D has primary authority for the `acct.corp.com` zone and secondary authority for each of the other two zones. Server A is both a router and a caching-only server. As a caching-only server, it caches information it receives from queries out of the parent domain.

In the same example, if the three zones were located in three different cities or countries, you could configure Server A at `mktg.corp.com` as a stub server for the other two remote zones. That way, all of the resource records for the remote sites would reside on servers (Server C and Server D) local to the `eng.corp.com` and `acct.corp.com` domains. The master server, Server A, would retain only the resource records for the name server that is local to each subdomain. Server A would query Server C and Server D for information about the machines in the `eng.corp.com` and `acct.corp.com` domains instead of searching its own master DNS database.

Figure 8–2: Sample Large DNS Configuration

ZK-1161U-AI

8.2 Dynamic Updates

Typically, whenever you connect a new host to a network, you need to rebuild the DNS database as explained in Section 8.9. If you do not update the DNS database, other computers on the network will not be able to resolve the new host's address.

However, some clients, particularly Tru64 UNIX systems that are configured for IPv6 networks and Microsoft Windows systems, can automatically update the DNS database for you. These clients support dynamic updates, which

allow hosts to inform the DNS master server that they are being added to or removed from the network. The clients simply specify their IP address and host name, and the `named` daemon automatically makes the appropriate changes in the DNS master data file. There is no need for intervention by the administrator of the master server, which saves the administrator a lot of effort in larger networks.

See Section 8.5.1.2 for information about configuring dynamic updates on the DNS master server.

8.3 Authentication of Dynamic Updates and Zone Transfers

DNS servers can provide cryptographic authentication of the data they receive from other systems. Authentication reduces the possibility that a rogue system can assume the identity of another system and send bogus DNS data file updates to servers.

The operating system provides support for symmetric cryptography, where two or more systems share a single private key for DNS authentication. A system that sends a DNS update to another system can use this key to generate a unique digital signature that corresponds to the data in the update. The system then attaches this signature to the update and sends the entire package to the target system. When the target system receives the signed update, it verifies the data by using the same private key to generate a second digital signature from the data. If the signatures match, the target system knows that the update came from a trusted system and that it is safe to use.

You can use cryptographic authentication for many purposes, including:

- Secure dynamic updates — Allow the master server to authenticate the updates it receives from clients.
- Secure zone updates — Allow the master server to authenticate zone transfer requests it receives from the slave servers, and subsequently, allow slave servers to authenticate the zone transfers they receive from the master server.

For either of these applications, if the data is not correctly signed (by a trusted host), it is rejected.

See Section 8.6 for information about configuring authentication for dynamic updates and zone transfers.

8.4 Planning DNS

Figure 8–3 shows the DNS Setup Worksheet, which you can use to record the information required to configure DNS. If you are viewing this manual online, you can use the print feature of your browser to print a copy of

this worksheet. The following sections explain the information you need to record on the worksheet.

Figure 8–3: DNS Setup Worksheet

DNS Setup Worksheet		
Local domain name: _____		
Server		
Host name resolution: ___ /etc/hosts ___ DNS ___ NIS		
Dynamic updates: <input type="checkbox"/> Yes <input type="checkbox"/> No		
Authentication: <input type="checkbox"/> Dynamic updates <input type="checkbox"/> Zone transfers <input type="checkbox"/> None		
Zones		
Zone domain name:	Authority:	Data file and server address:
_____	<input type="checkbox"/> Primary <input type="checkbox"/> Secondary	_____
_____	<input type="checkbox"/> Primary <input type="checkbox"/> Secondary	_____
_____	<input type="checkbox"/> Primary <input type="checkbox"/> Secondary	_____
_____	<input type="checkbox"/> Primary <input type="checkbox"/> Secondary	_____
Forwarders		
Forwarder name: _____		
Client		
Server name:	Internet address:	
_____	_____	
_____	_____	
_____	_____	
_____	_____	
Host name resolution: ___ /etc/hosts ___ DNS ___ NIS		

Local domain name

For a master server, the domain for which the server has primary authority. For client systems, the parent domain of which your local system is a part. For example, if your system’s domain name is cxcxcx.abc.xyz.com, your local domain name is abc.xyz.com.

8.4.1 Server

Host name resolution

The order in which the local /etc/hosts file, DNS database, and NIS database are to be queried for host name resolution.

Indicate the order on the worksheet by placing the appropriate number next to each item. The following order is recommended:

1. Local hosts file
2. DNS database
3. NIS database

Dynamic updates

Check Yes if you want to enable dynamic client updates; otherwise, check No.

Authentication

If you want the master server to authenticate the DNS database updates it receives from clients, check Dynamic updates. If you want to authenticate zone transfers between master and slave servers, check Zone transfers. If you do not require authentication, check None.

If you plan to use the `nd6hostd` daemon to provide dynamic updates for IPv6 zones, do not enable authentication for these zones. The `nd6hostd` daemon does not support authentication.

Zone domain name

The name of the top-level domain in the zone.

Authority

If the server is a master server for the zone (maintains the zone database file), check Primary. If the server is a slave server for the zone (copies the zone database file from the master), check Secondary.

Data file and server address

For a master server, the full directory and file name specification for the file in which the master database of zone information will be stored.

For a slave server or stub server, the full directory and file name specification for the file in which a local copy of the database from the master server will be stored. Also, the IP address of the master server.

Forwarder name

The host name of a system or systems to which your server forwards queries that it cannot resolve locally. When the server receives a query that it cannot answer from its cache, it sends the query to a forwarder for resolution. If the forwarder cannot answer the query, the server might contact other servers directly. If your system is a Forward-only

server, you must include forwarder names; otherwise, forwarders are optional.

8.4.2 Client

Server name

The name of a server to contact for host name resolution. Specify up to three servers.

Internet address

A corresponding IP address for the server or servers.

Host name resolution

The order in which the local `/etc/hosts` file, DNS database, and NIS database are to be queried for host name resolution.

Indicate the order on the worksheet by placing the appropriate number next to each item. The following order is recommended:

1. Local hosts file
2. DNS database
3. NIS database

8.5 Configuring DNS

Use the SysMan Menu application of the Common Desktop Environment (CDE) Application Manager to configure DNS on servers and clients. To invoke the SysMan Menu application, follow the instructions in Section 1.1.1.

When you configure DNS, you must first set up the master server. You can configure the other systems in any order.

8.5.1 Configuring a Master Server

To configure a master server, do the following:

Note

If you are configuring an IPv6 master server, see Section 8.5.1.1 for more information.

1. Copy into the `/etc/namedb/src` directory the hosts file that you want to convert to the DNS hosts database.

To create the a new file from which the hosts database will be created, you can update the master server's local `/etc/hosts` file (see Section 2.3.7) and copy it into the `/etc/namedb/src` directory with the same `hosts` file name. If a system is in your DNS domain and is running DNS but is not included in the master server's hosts database, other systems in the domain cannot obtain its IP address.

2. From the SysMan Menu, select Networking→Additional Network Services→Domain Name Service (DNS(BIND))→Configure system as a DNS server to display the DNS Server Configuration dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman dns_server
```

3. Enter your local domain name, the domain for which the master server will have primary authority, in the Local Domain field.
4. Select MASTER in the DNS Server Type pull-down menu.
5. Indicate the order in which to resolve host name queries in the Host Name Resolution Order field. Open the pull-down menu and choose from the list of options. Administrators usually use either the DNS Database, Local Host File, NIS option or the Local Host File, DNS Database, NIS option; the latter is recommended. Your choice is recorded in the `/etc/svc.conf` file.

Alternatively, you can run the `svcsetup` script to customize service order selection. See Section 8.8 and `svcsetup(8)` for information about modifying the `svc.conf` file.

6. Select the Advanced DNS Options button to display the Advanced Options dialog box, which allows you to choose a different directory and files in which to save DNS server configuration information and cache data. Make changes, if necessary, then select OK to close the dialog box.
7. Select Next to display the Local Name Server list.
 - a. Select Add to display the Add Name Server dialog box.
 - b. Enter the host name and IP address for a name server that your master server will query for addresses it cannot resolve by itself.
 - c. Select OK to accept the entry. If the server is not a known host, select Yes to add it to the `/etc/hosts` file.
Repeat steps 7a through 7c, if necessary. It is best to specify two or three name servers.
 - d. Select OK to accept the list of name servers. The addresses are later recorded in the `/etc/resolv.conf` file.
8. Select the appropriate check box to create the DNS database. Specify the name of the source file to use in the Hosts File field. Use

`/etc/namedb/src/hosts` for the file you created in step 1 or the default for `/etc/hosts`. Select Next to continue.

9. Select the appropriate check box to start the `named` daemon and select Next to continue. The utility prompts you to change the host name of the system.
10. Select the appropriate check box to change the host name, if necessary. If you choose to change the host name, you are prompted to add `localhost` to the access control list. Select Yes to allow graphical user interfaces to be displayed properly on your newly renamed system.
11. Select Next to continue, then select Finish to save the configuration and start the `named` daemon.

You are informed that you successfully configured the system as a DNS server. Select OK to close the DNS Server Configuration dialog box.

You can also modify your server configuration after the initial setup. See the online help for more information.

To enable dynamic updates on a DNS master server for IPv6 or Microsoft Windows network environments, see Section 8.5.1.2 and Section 8.6.

8.5.1.1 Configuring an IPv6 Master Server

Configuring an IPv6 master server is similar to configuring an IPv4 master server with a few exceptions. The following sections describe the exceptions.

8.5.1.1.1 DNS Configuration Files

The `/usr/examples/ipv6/namedb` directory contains DNS configuration files that show sample IPv6 information for you to study and adapt to your environment. Of the files in that directory, the following files contain IPv6 information that show reverse lookup addresses and dynamic update examples:

- `/usr/examples/ipv6/namedb/ipv6.rev`
- `/usr/examples/ipv6/namedb/ipv6.db`
- `/usr/examples/ipv6/namedb/named.conf`

After you customize these files for your environment, save the original files in the `/etc/namedb` directory, then move the customized files to that directory.

8.5.1.1.2 Server Guidelines

To configure a DNS server to operate in an IPv6 network environment, review the following guidelines:

- Select a node to function as an IPv6 name server.

- Dedicate a zone to IPv6 addresses or add IPv6 addresses to your enterprise's current zone.
- If you want global IPv6 name services, you must delegate a domain under the `ip6.int` domain for the reverse lookup of IPv6 addresses. Send mail to the following address to request a domain for reverse lookups:

`bmannig@isi.edu`

See RFC 1886 for more information.

See Section 3.2.5 information on how to create a reverse lookup zone name.

- If the system is already configured as a DNS server, change the `/etc/resolv.conf` file to point to the local node for name lookups, as follows:

```
nameserver 127.0.0.1
```

8.5.1.2 Enabling Dynamic Updates to the DNS Database

To enable dynamic updates on a DNS master server for IPv6 or Microsoft Windows network environments, do the following:

Caution

Each time you reconfigure your DNS master server with the SysMan Menu, you must reenale dynamic updates by repeating these steps because your `named.conf` file will be rewritten.

1. Edit the `/etc/namedb/named.conf` file and add the `allow-update` substatement to the master zone statements (forward and reverse lookup) for which you want to enable dynamic updates, as follows:

```
zone "zone-name" {
    type master;
    file "file-name";
    allow-update { any; };
};

zone "rev-ip.in-addr.arpa" {
    type master;
    file "file-name.rev";
    allow-update { any; };
};
```

For example, if you are enabling dynamic updates in an IPv6 zone, the zone statements might appear as follows after the change:

```

zone "ipv6.site1.corp.example" {
    type master;
    file "ipv6.site1.db";
    allow-update { any; };
};
zone "0.4.c.8.0.0.0.4.c.8.0.1.0.0.1.2.0.0.f.5.IP6.INT" {
    type master;
    file "ipv6.site1.rev";
    allow-update { any; };
};

```

Note that specifying `any` in the `allow-update` substatements allows any client to update the master DNS database. If you prefer to limit access to the database, see Section 8.6 for information about enabling authentication of dynamic updates. (However, note that the `nd6hostd` daemon on IPv6 clients does not support authentication.)

2. Start or restart the named daemon. See the online help for more information.

For information about configuring Microsoft Windows 2000 systems on a network with Tru64 UNIX DNS servers, see the Best Practice for *Integrating Windows 2000 DNS Clients with Tru64 UNIX DNS Services* at the following URL:

http://www.tru64unix.compaq.com/faqs/publications/best_practices

8.5.2 Configuring a Slave Server

To configure a slave server, invoke the SysMan Menu as documented in Section 1.1.1 and do the following:

1. From the SysMan Menu, select `Networking→Additional Network Services→Domain Name Service (DNS(BIND))→Configure system as a DNS server` to display the DNS Server Configuration dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman dns_server
```

2. Enter your local domain name in the Local Domain field.
3. Select SLAVE in the DNS Server Type pull-down menu.
4. Indicate the order in which to resolve host name queries in the Host Name Resolution Order field. Open the pull-down menu and choose from the list of options. Administrators usually use either the DNS Database, Local Host File, NIS option or the Local Host File, DNS Database, NIS option; the latter is recommended. Your choice is recorded in the `/etc/svc.conf` file.

Alternatively, you can run the `svcsetup` script to customize service order selection. See Section 8.8 and `svcsetup(8)` for information about modifying the `svc.conf` file.

5. Select the Advanced DNS Options button to display the Advanced Options dialog box, which allows you to choose a different directory and files in which to save DNS server configuration information and cache data. Make changes, if necessary, then select OK to close the dialog box.
6. Select Next to display the Zones Served list.
 - a. Select Add to display the Add Zone dialog box.
 - b. Select the Slave radio button in the Authority field and enter the name of the zone (domain) for which this server will have secondary authority.
 - c. Enter the name of the local file in which to store a copy of the database of zone information from the master server. Also, enter the IP address of the master server.
 - d. Select OK to accept the entry. Repeat steps 6a through 6d for additional entries. At the very least, you must add a forward lookup entry and reverse lookup entry for each zone.

Given the following `/etc/namedb/named.conf` file on the master server, you would add entries in the slave's Zones Served list for the `domain.suffix` and `nn.nnn.in-addr.arpa` zones:

```
zone domain.suffix {
    type master;
    file "hosts.db";
};

zone nn.nnn.in-addr.arpa {
    type master;
    file "hosts.rev";
};
```

7. Select Next to display the Local Name Server list.
 - a. Select Add to display the Add Name Server dialog box.
 - b. Enter the host name and IP address for a name server that your slave server will query for addresses that it cannot resolve by itself.
 - c. Select OK to accept the entry. If the server is not a known host, select Yes to add it to the `/etc/hosts` file.

Repeat steps 7a through 7c, if necessary. It is best to specify two or three name servers.

- d. Select Next to accept the list of name servers. The addresses are later recorded in the `/etc/resolv.conf` file.
8. Select the appropriate check box to start the `named` daemon and select Next to continue. The utility prompts you to change the host name of the system.
9. Select the appropriate check box to change the host name, if necessary. If you choose to change the host name, you are prompted to add `localhost` to the access control list. Select Yes to allow graphical user interfaces to be displayed properly on your newly renamed system.
10. Select Next to continue, then select Finish to save the configuration and start the `named` daemon.

You are informed that you successfully configured the system as a DNS server. Select OK to close the DNS Server Configuration dialog box.

You can also modify your server configuration after the initial setup. See the online help for more information.

8.5.3 Configuring a Caching-Only Server

To configure a caching-only server, invoke the SysMan Menu as documented in Section 1.1.1 and do the following:

1. From the SysMan Menu, select Networking→Additional Network Services→Domain Name Service (DNS(BIND))→Configure system as a DNS server to display the DNS Server Configuration dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman dns_server
```

2. Enter your local domain name in the Local Domain field.
3. Select CACHING in the DNS Server Type pull-down menu.
4. Indicate the order in which to resolve host name queries in the Host Name Resolution Order field. Open the pull-down menu and choose from the list of options. Administrators usually use either the DNS Database, Local Host File, NIS option or the Local Host File, DNS Database, NIS option; the latter is recommended. Your choice is recorded in the `/etc/svc.conf` file.

Alternatively, you can run the `svcsetup` script to customize service order selection. See Section 8.8 and `svcsetup(8)` for information about modifying the `svc.conf` file.

5. Select the Advanced DNS Options button to display the Advanced Options dialog box, which allows you to choose a different directory and

files in which to save DNS server configuration information and cache data. Make changes, if necessary, then select OK to close the dialog box.

6. Select Next to display the Local Name Server list.
 - a. Select Add to display the Add Name Server dialog box.
 - b. Enter the host name and IP address for a name server that your caching-only server will query for addresses that it cannot resolve by itself.
 - c. Select OK to accept the entry. If the server is not a known host, select Yes to add it to the `/etc/hosts` file.
Repeat steps 6a through 6c, if necessary. It is best to specify two or three name servers.
 - d. Select Next to accept the list of name servers. The addresses are later recorded in the `/etc/resolv.conf` file.
7. Select the appropriate check box to start the `named` daemon and select Next to continue. The utility prompts you to change the host name of the system.
8. Select the appropriate check box to change the host name, if necessary. If you choose to change the host name, you are prompted to add `localhost` to the access control list. Select Yes to allow graphical user interfaces to be displayed properly on your newly renamed system.
9. Select Next to continue, then select Finish to save the configuration and start the `named` daemon.
You are informed that you successfully configured the system as a DNS server. Select OK to close the DNS Server Configuration dialog box.

You can also modify your server configuration after the initial setup. See the online help for more information.

8.5.4 Configuring a Forward-Only Server

To configure a forward-only server, invoke the SysMan Menu as documented in Section 1.1.1 and do the following:

1. From the SysMan Menu, select Networking→Additional Network Services→Domain Name Service (DNS(BIND))→Configure system as a DNS server to display the DNS Server Configuration dialog box.
Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman dns_server
```
2. Enter your local domain name in the Local Domain field.
3. Select FORWARDER in the DNS Server Type pull-down menu.

4. Indicate the order in which to resolve host name queries in the Host Name Resolution Order field. Open the pull-down menu and choose from the list of options. Administrators usually use either the DNS Database, Local Host File, NIS option or the Local Host File, DNS Database, NIS option; the latter is recommended. Your choice is recorded in the `/etc/svc.conf` file.

Alternatively, you can run the `svcsetup` script to customize service order selection. See Section 8.8 and `svcsetup(8)` for information about modifying the `svc.conf` file.
5. Select the Advanced DNS Options button to display the Advanced Options dialog box, which allows you to choose a different directory and files in which to save DNS server configuration information and cache data. Make changes, if necessary, then select OK to close the dialog box.
6. Select Next to display the Forwarders list.
 - a. Select the appropriate check box to indicate that you want to configure the system as a forward-only server.
 - b. Select Add to display the Add Forwarder dialog box.
 - c. Enter the IP address for a forwarder, a name server that your forward-only server will query for addresses on remote networks (like the Internet).
 - d. Select OK to accept the entry. If the server is not a known host, select Yes to add it to the `/etc/hosts` file.

Repeat steps 6b through 6d, if necessary. It is best to specify two or three forwarders.
 - e. Select Next to accept the list of forwarders. The addresses are later recorded in the `/etc/resolv.conf` file.
7. Select Next to display the Local Name Server list.
 - a. Select Add to display the Add Name Server dialog box.
 - b. Enter the host name and IP address for a name server that your forward-only server will query for addresses on the local network.
 - c. Select OK to accept the entry. If the server is not a known host, select Yes to add it to the `/etc/hosts` file.

Repeat steps 7a through 7c, if necessary. It is best to specify two or three name servers.
 - d. Select Next to accept the list of name servers. The addresses are later recorded in the `/etc/resolv.conf` file.

8. Select the appropriate check box to start the `named` daemon and select Next to continue. The utility prompts you to change the host name of the system.
9. Select the appropriate check box to change the host name, if necessary. If you choose to change the host name, you are prompted to add `localhost` to the access control list. Select Yes to allow graphical user interfaces to be displayed properly on your newly renamed system.
10. Select Next to continue, then select Finish to save the configuration and start the `named` daemon.

You are informed that you successfully configured the system as a DNS server. Select OK to close the DNS Server Configuration dialog box.

You can also modify your server configuration after the initial setup. See the online help for more information.

8.5.5 Configuring a Stub Server

To configure a stub server, invoke the SysMan Menu as documented in Section 1.1.1 and do the following:

Note

When configuring stub service, run the SysMan Menu application on the server that will have authority for the subzone, not on the master server. See the definition for a stub server in Section 8.1 for more information.

1. From the SysMan Menu, select Networking→Additional Network Services→Domain Name Service (DNS(BIND))→Configure system as a DNS server to display the DNS Server Configuration dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman dns_server
```

2. Enter your local domain name in the Local Domain field.
3. Select STUB in the DNS Server Type pull-down menu.
4. Indicate the order in which to resolve host name queries in the Host Name Resolution Order field. Open the pull-down menu and choose from the list of options. Administrators usually use either the DNS Database, Local Host File, NIS option or the Local Host File, DNS Database, NIS option; the latter is recommended. Your choice is recorded in the `/etc/svc.conf` file.

Alternatively, you can run the `svcsetup` script to customize service order selection. See Section 8.8 and `svcsetup(8)` for information about modifying the `svc.conf` file.

5. Select the Advanced DNS Options button to display the Advanced Options dialog box, which allows you to choose a different directory and files in which to save DNS server configuration information and cache data. Make changes, if necessary, then select OK to close the dialog box.
6. Select Next to display the Zones Served list.
 - a. Select Add to display the Add Zone dialog box.
 - b. Select the Stub radio button in the Authority field. Enter the name of the stub zone (domain).
 - c. Enter the name of the local file in which to store a copy of the database of zone information from the master server. Also, enter the IP address of the master server.
 - d. Select OK to accept the entry. Repeat steps 6a through 6d for additional entries. At the very least, you must add a forward lookup entry and a reverse lookup entry for each zone.

Given the following `/etc/namedb/named.conf` file on the master server, you would add entries in the slave's Zones Served list for the `domain.suffix` and `nn.nnn.in-addr.arpa` zones:

```
zone domain.suffix {
    type master;
    file "hosts.db";
};

zone nn.nnn.in-addr.arpa {
    type master;
    file "hosts.rev";
};
```

7. Select Next to display the Local Name Server list.
 - a. Select Add to display the Add Name Server dialog box.
 - b. Enter the host name and IP address for a name server that your stub server will query for addresses that it cannot resolve by itself.
 - c. Select OK to accept the entry. If the server is not a known host, select Yes to add it to the `/etc/hosts` file.
Repeat steps 7a through 7c, if necessary. It is best to specify two or three name servers.
 - d. Select Next to accept the list of name servers. The addresses are later recorded in the `/etc/resolv.conf` file.

8. Select the appropriate check box to start the `named` daemon and select Next to continue. The utility prompts you to change the host name of the system.
9. Select the appropriate check box to change the host name, if necessary. If you choose to change the host name, you are prompted to add `localhost` to the access control list. Select Yes to allow graphical user interfaces to be displayed properly on your newly renamed system.
10. Select Next to continue, then select Finish to save the configuration and start the `named` daemon.

You are informed that you successfully configured the system as a DNS server. Select OK to close the DNS Server Configuration dialog box.

You can also modify your server configuration after the initial setup. See the online help for more information.

8.5.6 Configuring a DNS Client

To configure a DNS client, invoke the SysMan Menu as documented in Section 1.1.1 and do the following:

1. From the SysMan Menu, select Networking→Additional Network Services→Domain Name Service (DNS(BIND))→Configure system as a DNS client to display the Configure DNS Client dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman dns_client
```

2. Enter your local domain name in the Local Domain field.
3. Select Add to add a name server.
4. Enter the host name and the IP address for the name server.
The addresses are recorded in the `/etc/resolv.conf` file, where the resolver uses them to determine the IP addresses of name servers it will query.
5. Select OK to add the host name to the list of name servers. If the specified host is not listed in the `/etc/hosts` file, the script prompts you to add it to that file. Select Yes or No.

To add other name servers, repeat steps 3 through 5. You can specify up to three name servers.

6. Indicate the order in which to resolve host name queries in the Host Name Resolution Order field. Open the pull-down menu and choose from the list of options. Administrators usually use either the DNS Database, Local Host File, NIS option or the Local Host File, DNS

Database, NIS option; the latter is recommended. Your choice is recorded in the `/etc/svc.conf` file.

Alternatively, you can run the `svcsetup` script to customize service order selection. See Section 8.8 and `svcsetup(8)` for information about modifying the `svc.conf` file.

7. Configure your system to search alternate domains for address resolution by doing the following:
 - a. Select Domains Searched to display the associated dialog box.
 - b. Select Add to display the Add/Modify dialog box.
 - c. Enter the name of a domain to search. Your local domain is searched by default; you do not need to enter it.
 - d. Select OK to accept the entry. Repeat steps 7b through 7d, if necessary. You can specify up to six domains.
 - e. Select OK to accept the list of domains to be searched.
8. Select OK to accept the configuration. The script prompts you to change the host name of the system.
9. Select Yes or No as appropriate. If you choose Yes to change the host name, you are prompted to add `localhost` to the access control list. Select Yes to allow graphical user interfaces to be displayed properly on your newly renamed system.
10. Select OK to close the Configure DNS Client dialog box.

You can also modify your client configuration after the initial setup. See the online help for more information.

For IPv6 network environments, to enable dynamic updates for a DNS client, do the following:

1. Run the `ip6_setup` script and enable dynamic updates of IPv6 addresses by answering `y` and provide a fully qualified domain name for the IPv6 host. See Section 3.4.2 and Section 3.5.1 for more information.
2. Configure the DNS/BIND server to allow the updates (see Section 8.5.1.2).

If you do not want to enable dynamic updates, you must still run the `ip6_setup` script, but no special DNS configuration is necessary.

8.6 Configuring Authentication

The following sections describe how to configure authentication on DNS servers for the following purposes:

- Secure dynamic updates
- Secure zone transfers

Authentication serves a purpose only when the private key remains a secret between the servers; therefore, it is prudent to change this key frequently and save the key file as specified in the following sections to prevent the key from being compromised.

8.6.1 Configuring Secure Dynamic Updates

If you plan to use the `nd6hostd` daemon to dynamically update IPv6 zones, do not enable authentication for these zones. The `nd6hostd` daemon does not support authentication.

To configure a master server to authenticate dynamic updates it receives from new DNS clients (Microsoft Windows systems), do the following:

Caution

Each time you reconfigure your DNS master server with the SysMan Menu, you must reenable secure client updates by repeating these steps because your `named.conf` file will be rewritten.

1. Generate a private key using the `dnskeygen` command, as follows:

```
# dnskeygen -H size -h -c -n key-name
```

Valid key sizes are 512, 576, 640, 704, 768, 832, 896, 960, and 1024. Larger keys are more cumbersome, but they are more secure.

You can supply any name for a key, but it is best to give the keys canonical names so they are easy to distinguish. For example, if hosts from the `xyz.corp.com` zone send dynamic updates to your master server, `marlin.xyz.corp.com`, you might want to name your key `xyznet-marlin_update`.

The `dnskeygen` command produces two files:

- `K<key-name><proto-id><key-id>.key`
- `K<key-name><proto-id><key-id>.private`

Hereafter, these files are referred to as the `.key` and `.private` files.

For more information about generating keys, see the `dnskeygen(1)` reference page.

2. Create a file, possibly `named.keys`, to contain the key configuration statement for the update. This file must be read/writeable only by

superuser to prevent the private key from being compromised. For example:

```
# cd /etc/namedb
# touch key-config-file
# chmod 600 key-config-file
```

3. Incorporate the key information from the `.private` file into the `key-config-file` by adding the following key statement:

```
key key-name {
    algorithm hmac-md5;
    secret "generated-key";
};
```

In the key statement, replace `key-name` with the name of the key and `generated-key` with the entire private key as it appears in the `.private` file. It is best to enter the key by opening the `.private` file in another window, copying the necessary key text, and pasting the text into the text editor window. There must be no line feeds or spaces between the quotes that contain the key; if even one character is entered incorrectly, authentication fails.

4. Add the following include statement to the top of the `/etc/namedb/named.conf` file:

```
include "/etc/namedb/key-config-file";
```

Replace `key-config-file` with the name of the key configuration file you created in steps 2 and 3.

When the `named` daemon starts and reads the DNS data file, it calls the `key-config-file` and parses its contents.

5. Enable secure dynamic updates for the master zone by adding the `allow-update` substatement to the master zone statements (for forward and reverse lookups) in the `named.conf` file :

```
zone "zone-name" {
    type master;
    file "file-name";
    allow-update {
        key key-name;
    };
};

zone "rev-ip.in-addr.arpa" {
    type master;
    file "hosts.rev";
    allow-update {
        key key-name;
    };
};
```

Replace *key-name* with the name of the file you created in steps 2 and 3.

Specifying a key in this statement ensures that updates are successful only if they are signed with the private key.

6. Restart the `named` daemon by issuing the following command:

```
# /sbin/init.d/named restart
```

Once you have configured the master server to support secure dynamic DNS updates from new hosts, you can distribute the private key as necessary to administrators who need to add these hosts to the network. It is best to physically distribute the key on magnetic or optical media as opposed to sending it over the network where it can be compromised.

You can format a floppy for this purpose. See `mttools(1)` for information about formatting and reading Microsoft Windows-compatible floppy disks on a Tru64 UNIX system. If the described tools are not available, you need to install the `OSFDOSTOOLS` subset.

For information about configuring Microsoft Windows 2000 systems on a network with Tru64 UNIX DNS servers, see the Best Practice for *Integrating Windows 2000 DNS Clients with Tru64 UNIX DNS Services* at the following URL:

http://www.tru64unix.compaq.com/faqs/publications/best_practices

Note that when clients send updates to the master server, the `named` daemon does not immediately update the master database files. It creates temporary `database.ixfr` and `database.log` files where it logs the changes until they can be incorporated into the database. However, the daemon does become aware of the updates almost immediately in memory. You can verify them with the `nslookup` command as explained in Section 8.10.1.

8.6.2 Configuring Secure Zone Transfers

To configure a master server and slave servers to use authentication for zone transfers, do the following:

Caution

Each time you reconfigure DNS with the SysMan Menu, you must reenable secure zone transfers by repeating these steps because your `named.conf` file will be rewritten.

1. On the master server, perform steps 1–4 as specified in Section 8.6.1.

When creating a key name, choose a name that describes the zone transfer. For example, if the master server, `marlin.xyz.corp.com`, is sending updates to the slave server, `minnow.xyz.corp.com`, for the `xyz.corp.com` zone, you might name the key `xyznet-marlin-minnow_transfer`.

2. On the master server, add the `allow-transfer` substatement to the master zone statements (for forward and reverse lookups) in the `/etc/namedb/named.conf` file.

```
include "/etc/namedb/key-file";
.
.
.
zone "zone-name" {
    type master;
    file "hosts.db";
    allow-transfer {
        key key-name;
    };
}

zone "rev-ip.in-addr.arpa" {
    type master;
    file "hosts.rev";
    allow-transfer {
        key key-name;
    };
};
```

Replace `key-name` with the name of the key as you specified it in the key configuration file you created in steps 2 and 3 of Section 8.6.1.

Adding this server statement ensures that the master servers transfers the zone only if the request is signed with the private key. It also ensures that the master server signs the zone transfer with the key before it sends the data to the slave server.

3. Transfer the key configuration file (`key-config-file` or `named.keys`) over from the master server to the slave server(s). It is best to physically transfer this file on magnetic or optical media as opposed to sending it over the network where it can be compromised.

You can format a floppy for this purpose. See `mttools(1)` for information about formatting and reading Microsoft Windows-compatible floppy disks on a Tru64 UNIX system. If the described tools are not available, you need to install the `OSFDOSTOOLS` subset.

On the slave server(s), ensure that the permissions are set for read/writable only by superuser:

```
# chmod 600 key-config-file
```

4. On the slave server(s), add an include statement to the `named.conf` file to call the `key-config-file`. Also, insert the server statement after the include statement and before any zone statements:

```
include "/etc/namedb/key-config-file";
.
.
.
server ip-address {
    keys {key-name};
};
```

Replace `key-config-file` with the name of the key configuration file you copied over from the master server. Replace `ip-address` with the IP address of the master server. Finally, replace `key-name` with the name of the key you specified in the `key-config-file`.

Adding the `server` statement ensures that the slave server signs requests for zone transfers from the master server with the private key. It also ensures that the slave server authenticates signed zone transfers from the master server before it incorporates them into its data files.

5. Restart the `named` daemon on the master server and the slave server(s) by issuing the following command:

```
# /sbin/init.d/named restart
```

8.6.3 Authentication Example

The following examples show sample `named.keys` and `named.conf` files that implement both secure dynamic updates and secure zone transfers. These configuration files describe a network in which there is a DNS master server called `marlin.ocean.corp.com` and a slave server called `minnow.ocean.corp.com`.

Example 8–1: Sample `named.keys` File for Authentication

```
key oceannet-client_update {1
    algorithm hmac-md5;2
    secret "1SYbJjbTOLH2DB+kRpf0fcTJk0mOca90GDGdn5R7L2vPhyCx
daGhHp0o2pDU+PSzclE3Yk6Xg8jOkpRExx+2yw=="3
};

key oceannet-marlin-minnow_transfer {4
    algorithm hmac-md5;
    secret "648NyJi33LMhf00iavHjbkgqcTMJ71ZD4/r0DF9wgIQ2WH2b
peHLYjz2qYMrx1dMYw9E9gDp6F6LTMDHHCvFlw=="
```

In Example 8–1, the lines serve the following purpose:

- ❶ Defines the `oceannet-client_update` key, which will be used for secure dynamic updates from clients in the `ocean.corp.com` zone.
- ❷ Specifies the encryption algorithm. Keys for dynamic updates and zone transfers must be `hmac-md5`.
- ❸ Specifies the key string. This string must contain no spaces or carriage returns.
- ❹ Defines the `oceannet-marlin-minnow_transfer` key, which will be used for zone transfers between the master server, `marlin.ocean.corp.com`, and the slave server, `minnow.ocean.corp.com`.

Example 8–2: Sample Master Server `named.conf` File for Authentication

```
include "/etc/namedb/named.keys";❶

options {
    directory "/etc/namedb/";
};

zone "0.0.127.in-addr.arpa" {
    type master;
    file "named.local";
};

zone "ocean.corp.com" {
    type master;
    file "hosts.db";
    allow-update {
        key oceannet-client_update;❷
    };
    allow-transfer {
        key oceannet-marlin-minnow_transfer;❸
    };
};

zone "6.134.20.in-addr.arpa" {
    type master;
    file "hosts.rev";
    allow-update {
        key oceannet-client_update;❷
    };
    allow-transfer {
        key oceannet-marlin-minnow_transfer;❸
    };
};

zone "." {
```

Example 8–2: Sample Master Server named.conf File for Authentication (cont.)

```
        type hint;
        file "named.ca";
};
```

In Example 8–2, the lines serve the following purpose:

- ❶ Calls the aforementioned `named.keys` file into the `named.conf` file.
- ❷ Specify that dynamic updates for the `ocean.corp.com` zone must be authenticated with the `oceannet-client_update` key before they are incorporated into the DNS database.
- ❸ Specify that zone transfer requests for the `ocean.corp.com` zone must be authenticated with the `oceannet-marlin-minnow_transfer` key before any data is sent to the slave server(s).

Example 8–3: Sample Slave Server named.conf File for Authentication

```
include "/etc/namedb/named.keys";

server 20.134.6.2 {
    keys { oceannet-marlin-minnow_transfer };❶
};

options {
    directory "/etc/namedb/";
};

zone "0.0.127.in-addr.arpa" {
    type master;
    file "named.local";
};

zone "pubs.zk3.dec.com" {
    type slave;
    file "/etc/namedb/hosts.db";
    masters {
        20.134.6.2❷;
    };
};

zone "6.134.20.in-addr.arpa" {
    type slave;
    file "/etc/namedb/hosts.rev";
    masters {
        20.134.6.2;❷
    };
};
```

Example 8–3: Sample Slave Server `named.conf` File for Authentication (cont.)

```
};  
};  
  
zone "." {  
    type hint;  
    file "named.ca";  
};
```

In Example 8–3, the lines serve the following purpose:

- 1 Specifies that the slave server is to use the `oceannet-marlin-minnow_transfer` key for authentication of all communication between itself and `20.134.6.2` (`marlin.ocean.corp.com`).
- 2 Specify that `20.134.6.2` is the master server for the `ocean.corp.com` zone, and that it will provide the authoritative data for that zone.

For more information about the statements in the `named.conf` file, see `named.conf(4)` and the *Bind Configuration File Guide* on the Tru64 UNIX Documentation CD-ROM.

8.7 Deconfiguring DNS

Use the SysMan Menu application of the Common Desktop Environment (CDE) Application Manager to deconfigure DNS servers and clients. To invoke the SysMan Menu application, follow the instructions in Section 1.1.1.

When you deconfigure DNS, the service stops and the DNS server and client configuration information is deleted from the system. This action cannot be undone. To restore DNS, you must configure it again using the SysMan Menu.

To deconfigure DNS, do the following:

1. From the SysMan Menu, select **Networking**→**Additional Network Services**→**Domain Name Service (DNS(BIND))**→**Deconfigure DNS** on this system to display the Deconfigure DNS dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman dns_deconfigure
```

2. Select **Yes** to deconfigure DNS on the system.
3. Select **OK** to close the Deconfigure DNS dialog box.

8.8 Modifying the `svc.conf` File with `svcsetup`

You can modify the `/etc/svc.conf` file without running the DNS Configuration application. To do this, you invoke the `svcsetup` script using the following command:

```
# /usr/sbin/svcsetup
```

Once invoked, use the following steps to edit the `/etc/svc.conf` file:

1. Press the Return key following the informational messages to continue.
2. Press the Return key to choose the `m` option from the Configuration Menu.
3. Choose option 2 from the Change Menu. Option 2 corresponds to the `hosts` database.
4. Enter the number that corresponds to the order in which you want the services running on your system queried for `hosts` data.

Listing local first means that the local `/etc/hosts` file is searched first for the requested information. If the information is not found locally, then DNS servers, NIS servers, or both, are queried, depending on which options you choose.

Note

For better performance, it is best if the first service that your system queries for all databases is local, regardless of what services you are running.

Choose option 3, 4, 5, or 6 to configure the `svc.conf` file so that DNS serves `hosts` information.

The `svcsetup` script indicates that it is updating the `/etc/svc.conf` file. When `svcsetup` is finished updating the file, the script notifies you and the system prompt (`#`) is displayed.

8.9 Updating DNS Data Files on the Master Server

If you have not configured dynamic updates, as discussed in Section 8.2 and Section 8.5.1.2, you will need to manually update the DNS data files when you connect new hosts to the network.

To add a new host, follow these steps:

1. Edit the `/etc/namedb/src/hosts` file to add the new host.
2. Change to the `/etc/namedb` directory and enter one of the following commands:

```
# make hosts
# make all
```

After you edit the `hosts` file and enter the `make` command, the DNS conversion scripts (which are in the `/etc/namedb/bin` directory) do the following for you:

1. Create the new hosts databases: `named.local` and `named.ca`.
2. Place the new databases in the `/etc/namedb` directory.
3. Send a signal to the `named` daemon to reload all databases that have changed.

Note

If you have manually entered mail exchanger (MX) records in the `named.local` file, these records are lost. You will have to edit the `named.local` file and add the MX records.

The DNS database conversion scripts also increment the serial number field of the start of authority (SOA) entry in the database file and inform the slave servers that it is time to refresh their data.

The process is the same for all of the valid files in the master server's `/etc/namedb/src` directory. Scripts are provided to create the `named.local` and `named.ca` databases.

8.10 Obtaining Host Name and IP Address Information

There are several ways that you can obtain information about host names, IP addresses, and user information from a system using DNS. The following sections provide an introduction to two commands: `nslookup` and `whois`.

8.10.1 The `nslookup` Command

You can use the `nslookup` command to noninteractively and interactively query DNS for information about hosts on local and remote domains. You can also find information about DNS resource records such as mail exchanger (MX), name server (NS), and so forth.

For a noninteractive query, use the following syntax:

```
nslookup hostname
```

The output is the server name and address and the host name and address.

For an interactive query, use the following syntax:

```
nslookup
```

The output is the default server name and address and the `nslookup` prompt, a greater than sign (>).

For example, to obtain information about MX, you need to query `nslookup` interactively, supplying a valid domain name. The following example shows how to find the mail recipient for the domain `corp.com`:

```
# nslookup
Default Server: localhost
Address: 127.0.0.1

> set querytype=mx
> corp.com
Server: localhost
Address: 127.0.0.1
findmx.corp.com preference = 100, mail exchanger = gateway.corp.com
gateway.corp.com inet address = 128.54.54.79
> Ctrl/D
#
```

A good way to learn how to use the `nslookup` command is to experiment with it. To obtain a list of the interactive `nslookup` command options, enter a question mark (?) at the `nslookup` prompt. For further information, see `nslookup(1)`.

For a detailed description of the many different types of DNS resource records, see Appendix H.

8.10.2 NIC whois Service

The Network Information Center (NIC) `whois` service allows you to access the following information about a domain:

- The name of the domain
- The name and address of the organization responsible for the domain
- The domain's administrative, technical, and zone contacts
- The host names and network addresses of sites providing DNS for the domain
- The registered users in the domain

For example, to use the NIC `whois` service to obtain information about a domain named `compaq.com`, use the `whois` command and specify the domain name as follows:

```
# whois compaq.com
Registrant:
Compaq Computer Corporation (COMPAQ-DOM)
P.O. Box 692000
Houston, TX 77269

Domain Name: COMPAQ.COM
:
```

The InterNIC Registration Services database contains ONLY non-military and non-US Government Domains and contacts. Other associated whois servers:

American Registry for Internet Numbers	- whois.arin.net
European IP Address Allocations	- whois.ripe.net
Asia Pacific IP Address Allocations	- whois.apnic.net
US Military	- whois.nic.mil
US Government	- whois.nic.gov

To query other whois servers, use the `-h` option:

```
# whois -h whois.nic.gov whitehouse.gov
Whitehouse Public Access (WHITEHOUSE-DOM)
725 17th Street NW Room NEOB 4208
Washington, DC 20503
```

```
Domain Name: WHITEHOUSE.GOV
Status: ACTIVE
Domain Type: Federal
```

```
:
```

Network Information Service

The Network Information Service (NIS, formerly Yellow Pages) is a distributed data lookup service for sharing information on a local area network (LAN). NIS allows you to coordinate the distribution of database information throughout your networked environment.

This chapter describes:

- The NIS environment
- How to configure your system for NIS
- How to manage NIS servers and clients

For introductory information on NIS, see `nis_intro(7)`. For troubleshooting information, see Section 15.10 for clients and Section 15.9 for servers.

9.1 NIS Environment

In an NIS environment, systems can have the following roles:

- Master server — A system that stores the master copy of the NIS database files, or maps, for the domain in the `/var/yp/DOMAIN` directory and propagates them at regular intervals to the slave servers. Only the master maps can be modified. Each domain can have only one master server.
- Slave server — A system that obtains and stores copies of the master server's NIS maps. These maps are updated periodically over the network. If the master server is unavailable, the slave servers continue to make the NIS maps available to clients. Each domain can have multiple slave servers distributed throughout the network.
- Client — Any system that queries NIS servers for NIS database information. Clients do not store and maintain copies of the NIS maps locally for their domain.

Figure 9–1 shows a domain in which there is a master server, two slave servers, and some clients.

Figure 9–1: NIS Configuration

ZK-1145U-AI

By default, NIS distributes the aliases (`mail.aliases`), `group`, `hosts`, `netgroup`, `networks`, `passwd`, `protocols`, `rpc`, and `services` databases. (The `mail.aliases` and `netgroup` databases are created exclusively for NIS.) You can also create and distribute the enhanced security extended profile database, and site-specific customized databases, such as NFS Automount and AutoFS maps.

To configure NIS with support for enhanced security, and optionally create secure versions of NIS maps, carefully read the instructions in the *Creating and Maintaining Accounts* chapter of the *Security* guide before proceeding with the setup described in this chapter. For information on creating Automount and AutoFS maps for distribution by NIS, see Appendix B. For information on creating and distributing other site-specific NIS maps, see the Section 9.4.6.

9.2 Planning NIS

This section describes the tasks you must complete before configuring NIS.

9.2.1 Verifying That the Additional Networking Services Subset is Installed

For NIS servers, verify that the Additional Networking Services subset is installed by entering the following command:

```
# setld -i | grep OSFINET
```

If the subset is not installed, install it by using the `setld` command. For more information on installing subsets, see `setld(8)`, the *Installation Guide*, or the *System Administration* manual.

9.2.2 Preparing for the Configuration

Figure 9–2 shows the NIS Setup Worksheet, which you can use to record the information required to configure NIS. If you are viewing this manual online, you can use the print feature to print a copy of this worksheet. The following sections explain the information you need to record on the worksheet.

Figure 9–2: NIS Setup Worksheet

NIS Setup Worksheet	
	Domain name: _____
Master Server	Database files for NIS maps: _____ _____ _____ _____ _____ /var/yp/src/mail.alias file: <input type="checkbox"/> Yes <input type="checkbox"/> No /var/yp/src/netgroup file: <input type="checkbox"/> Yes <input type="checkbox"/> No Setup options: _____ Slave name: _____ IP address: _____ Slave name: _____ IP address: _____
Slave Server	Setup options: _____ Master name: _____ IP address: _____ Slave name: _____ IP address: _____ Slave name: _____ IP address: _____
Client	Setup options: _____ Server name: _____ Server name: _____

Domain name

The domain name (1 to 31 alphanumeric characters). All systems in the domain must declare the same domain name.

An NIS domain is an administrative entity that consists of a master server, one or more slave servers, and numerous clients. All systems in a domain share the same set of NIS database files.

Note

An NIS domain name is not the same as a DNS domain name. Furthermore, an NIS domain name is case-sensitive. Be very careful when specifying it. If you configure the system with an incorrect NIS domain name, all NIS-related operations (such as logging in and `ls -l` commands) hang for several minutes, then fail.

NIS runs on each system in your network. You must decide what role each system will play within the NIS domain that you are creating. Select one host to be the master server; there can be only one master server for each domain. Select one or more hosts to be slave servers. The rest of the hosts can run as NIS clients. (The master server and all slave servers are also considered to be NIS clients.)

Once you have determined a role for each system, fill in the remainder of the worksheet as specified in the following sections.

9.2.2.1 Master Server

Database files for NIS maps

The files you want to make into NIS maps. Choose from the following list:

- `/etc/group`
- `/etc/hosts`
- `/etc/networks`
- `/etc/passwd`
- `/etc/protocols`
- `/etc/rpc`
- `/etc/services`

`/var/yp/src/mail.aliases` file

The `mail.aliases` file, which is based on the `/var/adm/send-mail/aliases` file, defines network-wide mail aliases. If you want to define and distribute mail aliases on your network, check Yes; otherwise, check No.

If you choose not to create a `mail.aliases` file, the `nissetup` script issues an informational message that it cannot find the `mail.aliases` file while it is building the NIS maps. For information on defining mail aliases, see `aliases(4)`.

`/var/yp/src/netgroup` file

The `netgroup` file defines network-wide groups and is used for permission checking when doing remote mounts, remote logins, and remote shells. If you want to define and distribute `netgroup` information on your network, check Yes; otherwise, check No.

If you choose not to create a `netgroup` file, the `nissetup` script issues an informational message that it cannot find the `netgroup` file while

it is building the NIS maps. For information on defining network groups, see `netgroup(4)`.

Setup options

The list of setup options for master servers is as follows. Write the options you want to use in the appropriate place in the worksheet.

- Run the `yppasswdd` daemon.

The `yppasswdd` daemon allows users to update their passwords in the master copy of the password file by issuing the `yppasswd` command on any system in the NIS domain. If you want users to be able to update their NIS-distributed passwords without administrator intervention, run the `yppasswdd` daemon.

The `yppasswdd` daemon runs only on the master server.

- Create base or enhanced security versions of the NIS maps.

Tru64 UNIX security can be configured in either base or enhanced authentication mode. Enhanced security includes an additional `prpasswd` map that contains extended user profile information. Before configuring NIS to distribute this `prpasswd` map, read Chapter 12 of the *Security* guide. It describes important operational differences and additional steps necessary for NIS configuration in a secure environment.

- Create NIS maps in `btree` format.

If you serve very large maps, you might want to have NIS maintain these maps as `btree` files, which significantly reduces the time required to build and push very large maps. However, the use of `btree` files might degrade performance slightly for relatively small maps.

If you intend to use enhanced security with NIS, it is best to maintain your maps in `btree` format.

- Run the `yplibind` daemon with the `-s` option, which requires the server to use a reserved port.

For security purposes, it is best to run NIS with the `-s` option.

- Lock the `yplibind` daemon to a particular domain name and server list by specifying the `-S` option.

Normally, hosts broadcast NIS requests on the network and the first available server answers the request. The `-s` option allows you to lock the `yplibind` daemon to a particular domain and set of servers. Requests are made directly to the specified servers, rather than being broadcast. For security purposes, it is best to run NIS with the `-S` option.

If you choose to run NIS with the `-S` option, you must know the host names and IP addresses of the servers to which you are locking the `ypbind` daemon. You will add them to the local `hosts` file during configuration.

Security Note

When using the `nissetup` script to set up an NIS server that is running with enhanced security, you must answer Yes to the question about locking the domain name and authorized servers (the `ypbind -S` option). For a master server, the server is bound to itself by default.

- Run NIS with the `-ypset` option or the `-ypsetme` option.

The `-ypset` option allows a user logged in as root on any system in your domain to bind your system to a particular server. The `-ypsetme` option allows `ypbind` to accept `-ypset` requests only from the local system. For security purposes, it is best to disallow all `ypset` requests.

- Create and distribute Automount or AutoFS maps.

The `automount` and `autofs` daemons, which are alternatives to mounting remote file systems in the `/etc/fstab` file, allow users to mount remote file systems on an as-needed basis. When you use NIS to distribute the maps for these daemons, you create the maps on the NIS master server and distribute them to NIS slave servers and clients. For information on creating these maps, see Appendix B. For information on administering the maps, see Section 10.1.2.

Whether or not you use Automount or AutoFS depends on your site's networking environment.

Slave name

The name of each slave server in the domain.

IP address

The IP address of each slave server in the domain.

9.2.2.2 Slave Server

Setup options

The list of setup options for slave servers is as follows. Write the options you want to use in the appropriate place in the worksheet.

- Maintain base or enhanced security versions of the NIS maps.
Tru64 UNIX security can be configured in either base or enhanced authentication mode. Enhanced security includes an additional `prpasswd` map that contains extended user profile information. Before configuring NIS to distribute this `prpasswd` map, read Chapter 12 of the *Security* guide. It describes important operational differences and additional steps necessary for NIS configuration in a secure environment.
- Maintain NIS maps in btree format.
If you serve very large maps, you might want NIS to maintain these maps as btree files, which significantly reduces the time required to push very large maps. However, it might degrade performance slightly for relatively small maps.
If you intend to use enhanced security with NIS, it is best to maintain your maps in btree format.
- Run the `ybind` daemon with the `-s` option, which requires the server to use a reserved port.
For security purposes, it is best to run NIS with the `-s` option.
- Lock the `ybind` daemon to a particular domain name and server list by using the `-S` option.
Normally, hosts broadcast NIS requests on the network and the first available server answers the request. The `-S` option allows you to lock the `ybind` daemon to a particular domain and set of servers. Requests are made directly to the specified servers, rather than being broadcast. For security purposes, it is best to run NIS with the `-S` option.
If you choose to run NIS with the `-S` option, you must know the host names and IP addresses of the servers to which you are locking the `ybind` daemon to successfully complete the configuration process.

Security Note

When using the `nissetup` script to set up an NIS server that is running with enhanced security, you must answer **Yes** to the question about locking the domain name and authorized servers (the `ybind -S` option). For a slave server, the server is bound to itself by default and optionally to the master server and any other slave servers.

- Run NIS with the `-ypset` option or the `-ypsetme` option.

The `-ypset` option allows a user logged in as root on any system in your domain to bind your system to a particular server. The `-ypsetme` option allows `ypbind` to accept `-ypset` requests only from the local system. For security purposes, it is best to disallow all `ypset` requests.

- Distribute Automount or AutoFS maps.

The `automount` and `autofs` daemons, which are alternatives to mounting remote file systems in the `/etc/fstab` file, allow users to mount remote file systems on an as-needed basis. When you use NIS to distribute the maps for these daemons, you can configure the slave server to receive the maps from the master server, distribute them to clients, and use them to mount remote file systems. For information on creating these maps, see Appendix B. For information on administering the maps, see Section 10.1.2.

Whether or not you use Automount or AutoFS depends on your site's networking environment.

Master name

The host name of the master server in your domain.

IP address

The IP address of the master server in your domain.

Slave name

The name of another slave server in your domain. Specify several servers.

IP address

The IP address of a slave server in your domain.

9.2.2.3 Client

Setup options

The list of setup options for clients is as follows. Write the options you want to use in the appropriate place in the worksheet.

- Run the `ypbind` daemon with the `-s` option, which requires the server to use a reserved port.
For security purposes, it is best to run NIS with the `-s` option.
- Lock the `ypbind` daemon to a particular domain name and server list by using the `-S` option.

Normally, hosts broadcast NIS requests on the network and the first available server answers the request. The `-s` option allows you to lock the `ypbind` daemon to a particular domain and set of servers. Requests are made directly to the specified servers, rather than being broadcast. For security purposes, it is best run NIS with the `-s` option.

If you choose to run NIS with the `-s` option, you must know the host names and IP addresses of the servers to which you are locking the `ypbind` daemon to successfully complete the configuration process.

- Run NIS with the `-ypset` option or the `-ypsetme` option.

The `-ypset` option allows a user logged in as `root` on any system in your domain to bind your system to a particular server. The `-ypsetme` option allows `ypbind` to accept `-ypset` requests only from the local system. For security purposes, it is best to disallow all `ypset` requests.

- Use Automount or AutoFS and the associated maps.

The `automount` and `autofs` daemons, which are alternatives to mounting remote file systems in the `/etc/fstab` file, allow users to mount remote file systems on an as-needed basis. When you use NIS to distribute the maps for these daemons, you can configure clients to receive the maps from the NIS master and slave servers and use the maps to mount remote file systems. For information on creating these maps, see Appendix B. For information on administering the maps, see Section 10.1.2.

Whether or not you use Automount or AutoFS depends on your site's networking environment.

Server name

The name of a master or slave server in your domain. Specify several servers.

9.3 Configuring NIS

Use the SysMan Menu application of the Common Desktop Environment (CDE) Application Manager to configure NIS on master servers, slave servers, and clients. To invoke the SysMan Menu application, follow the instructions in Section 1.1.1.

9.3.1 Configuring an NIS Master Server

You must configure the NIS master server before you configure the other systems. Prior to using the SysMan Menu or the `nissetup` script, you must log in as root and complete the following tasks:

1. Copy into the `/var/yp/src` directory the local `/etc` files that you intend to make into NIS maps for distribution. If a file is absent from the `/var/yp/src` directory while it is building the default NIS maps, the `nissetup` script issues an informational message that it could not find that particular file and continues building the maps.

Note

If you copied the `passwd` file into the `/var/yp/src` directory, remove the root entry from the file.

2. Optionally, create the `/var/yp/src/mail.aliases` file. If you already have a `/var/adm/sendmail/aliases` file on your local system, you can copy it to the `/var/yp/src` directory and edit it, if necessary. For information on the format of this file, see `aliases(4)`.
3. Optionally, create the `/var/yp/src/netgroup` file. For information on the format of this file, see `netgroup(4)`.
4. Edit the `/var/yp/Makefile` file.

If you are using the NIS master server to serve the `/etc/auto.master` and `/etc/auto.home` maps for Automount or AutoFS, you must remove the comment sign (`#`) from the beginning of each of the following lines. These lines were added to the Makefile for use by the `automount` and `autofs` daemons.

```

:
:
#all: passwd group hosts networks rpc services protocols netgroup \
#   aliases auto.home auto.master
:
:
#$(YPBDDIR)/$(DOM)/auto.home.time: $(DIR)/auto.home
#   -if [ -f $(DIR)/auto.home ]; then \
#       $(SED) -e "/^#/d" -e s/#.*$$// $(DIR)/auto.home | \
#       $(MAKEDBM) -a $(METHOD) - $(YPBDDIR)/$(DOM)/auto.home; \
#       $(TOUCH) $(YPBDDIR)/$(DOM)/auto.home.time; \
#       $(ECHO) "updated auto.home"; \
#       if [ ! $(NOPUSH) ]; then \
#           $(YPPUSH) auto.home; \
#           $(ECHO) "pushed auto.home"; \
#       else \
#           : ; \
#       fi \
#   else \
#       $(ECHO) "couldn't find $(DIR)/auto.home"; \
#   fi
#
```

```

#$(YPDBDIR)/$(DOM)/auto.master.time: $(DIR)/auto.master
#
#   -@if [ -f $(DIR)/auto.master ]; then \
#       $(SED) -e "/^#/d" -e s/#.*$$// $(DIR)/auto.master | \
#       $(MAKEDBM) -a $(METHOD) - $(YPDBDIR)/$(DOM)/auto.master; \
#       $(TOUCH) $(YPDBDIR)/$(DOM)/auto.master.time; \
#       $(ECHO) "updated auto.master"; \
#       if [ ! $(NOPUSH) ]; then \
#           $(YPPUSH) auto.master; \
#           $(ECHO) "pushed auto.master"; \
#       else \
#           : ; \
#       fi \
#   else \
#       $(ECHO) "couldn't find $(DIR)/auto.master"; \
#   fi
#
#
#auto.home: $(YPDBDIR)/$(DOM)/auto.home.time
#auto.master: $(YPDBDIR)/$(DOM)/auto.master.time
#
#$(DIR)/auto.home:
#$(DIR)/auto.master:

```

Place a comment sign (#) in front of the following lines:

```

all: passwd group hosts networks rpc services protocols netgroup \
aliases

```

If you are using the NIS master server to serve other site-specific maps, you must add entries for the maps to the Makefile. See Section 9.4.8.1 for information on adding entries for site-specific NIS maps, other than the `/etc/auto.master` and `/etc/auto.homemaps`, to the `/var/yp/Makefile` file.

5. Copy the `auto.master` and `auto.home` maps, or any other site-specific maps, to the `/var/yp/src` directory. For information on creating Automount or AutoFS maps, see Appendix B. For information on creating other site-specific maps, see the Section 9.4.8.1.

To continue to set up the master server, invoke the SysMan Menu as documented in Section 1.1.1 and do the following:

1. From the SysMan Menu, select **Networking→Additional Network Services→Configure Network Information Service (NIS)**. SysMan Menu invokes the `nissetup` script.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman nis
```

A message reminds you that your network must be established before setting up NIS, and that in order to set up an NIS server you must have the Additional Networking Services subset installed.

2. Enter `c` to continue.

3. Press Return following the script's explanation of `nissetup`, and then press Return again after the script explains the three types of systems in an NIS domain.
4. Enter and confirm your system's case-sensitive NIS domain name.
5. Choose option 1 to indicate that you are configuring the master server.
6. Following the `nissetup` script's explanation that there can be only one master server configured for each NIS domain, enter `c` and indicate whether or not you want to run the `yppasswdd` daemon. It is best to run the `yppasswdd` daemon on the NIS master server.
7. Indicate whether or not you intend to use enhanced security with NIS.
8. Indicate whether or not you want your NIS maps to be maintained as `btree` files.
9. Enter the names of hosts that will be slave servers for this domain. If you enter a host name that is not listed in the master server's `/etc/hosts` file, the `nissetup` script prompts you for its IP address.

Enter the names of the SLAVE servers in the `test_domain` domain.
Press Return to terminate the list.

```

Host name of slave server: host2
Host name of slave server: host3
  Cannot find host3 in the file /etc/hosts.
  To add host3 to the /etc/hosts file you MUST
  know host3's Internet (IP) address.

Would you like to add host3 to the /etc/hosts file
(y/n) [y]? y

What is host3's Internet (IP) address [no default] ?
120.105.1.28

Is 120.105.1.28 correct (y/n) [no default] ? y

Hostname of slave server: Return

```

The `nissetup` script displays the list of servers that you entered. You can redo the list to correct errors or continue with the setup procedure.

The `nissetup` script then creates the default NIS maps, displaying messages similar to the following as it does:

```

Creating default NIS maps. Please wait...
updated passwd
updated group
updated hosts
updated networks
updated rpc
updated services
updated protocols
updated netgroup
Finished creating default NIS maps.

```

10. Indicate whether or not you want to use the `-s` security option.

If you choose to run NIS with the `-s` option, the `ypbind` process runs in a secure mode. It is best to use this option.

11. Indicate whether or not you want to use the `-S` security option.

It is best to use this option. If you choose to run NIS with the `-S` option, you must enter the names of up to four NIS servers.

If you enter the name of a server that is not listed in the system's `/etc/hosts` file, the `nissetup` script prompts you for its IP address. When you are done entering the list of servers, press Return on a blank `Server n name` field and enter `c` to continue configuring NIS on your system.

12. Indicate whether or not you want to allow `ypset` requests on your system.

It is best to disallow all `ypset` requests. Press Return to accept the default, and confirm your choice.

13. Indicate whether or not you want your system to use all of the NIS databases served by the master server.

It is best to use all of the NIS databases.

If you choose to use all of the NIS databases, the `nissetup` script edits the `/etc/svc.conf` file to include the string `yp` for each database. It also edits the `/etc/passwd` and `/etc/group` files to include a plus sign followed by a colon (`+:`) at the end of each file. This enables your system to use NIS for each database listed. This symbol enables the files to be distributed by NIS. Continue with step 16.

If you choose not to use all of the NIS databases, enter `n` and continue with the next step.

14. Indicate whether or not you want to add a plus sign followed by a colon (`+:`) to the end of the local `/etc/passwd` and `/etc/group` files.

For your system to use the NIS-served `passwd` database, `group` database, or both, `+:` must be the last line in the file or files you want served by NIS. This applies to the `passwd` and `group` databases only.

Note

The service order selection for the `passwd` and `group` databases is handled by the Security Integration Architecture (SIA). If BSD is selected for `passwd` and `group` information in the `/etc/sia/matrix.conf` file, only the `+:` is required for your system to search NIS.

15. Indicate whether or not you want the `nissetup` script to invoke the `svcsetup` script.

If you answer yes, the `nissetup` script invokes the `svcsetup` script, which allows you to modify the database services selection file (the `svc.conf` file). See Section 9.3.4 for information on modifying the `svc.conf` file.

If you answer no, the `nissetup` script continues. You must edit the `svc.conf` file later if you want your system to use NIS to obtain database information other than `passwd` and `group` information.

16. Indicate whether or not to start the NIS daemons automatically.

If you answer yes, `nissetup` starts the daemons.

If you answer no, use the following command to start the daemons manually after `nissetup` exits and returns you to the system prompt (`#`):

```
# /sbin/init.d/nis start
```

9.3.2 Configuring a Slave Server

To configure a slave server, invoke the SysMan Menu as documented in Section 1.1.1 and do the following:

1. From the SysMan Menu, select `Networking→Additional Network Services→Configure Network Information Service (NIS)`. SysMan Menu invokes the `nissetup` script.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman nis
```

2. A message reminds you that your network must be established before setting up NIS, and that in order to set up an NIS server you must have the Additional Networking Services subset installed. Enter `c` to continue.
3. Press Return following the script's explanation of `nissetup`, and then press Return again after the script explains the three types of systems in an NIS domain.
4. Enter and confirm your system's case-sensitive NIS domain name.
5. Choose option 2 to indicate that you are configuring a slave server.
6. Enter `c` to continue following the `nissetup` script's explanation that the master server's list must include each slave server, and that the master server must be established in order for maps to be copied to the slave server.
7. Enter the name of the master server for your domain.

8. Indicate whether or not you intend to use enhanced security with NIS.
9. Indicate whether or not you want your NIS maps to be maintained as btree files.

After you indicate your choice, the script copies the default NIS maps from the master NIS server.

10. Indicate whether or not you want to use the `-s` security option.

If you choose to run NIS with the `-s` option, the `ypbind` process runs in a secure mode. It is best to use this option.

11. Indicate whether or not you want to use the `-S` security option.

It is best to use this option. If you choose to run NIS with the `-S` option, you must enter the names of up to four NIS servers.

If you enter the name of a server that is not listed in the system's `/etc/hosts` file, the `nissetup` script prompts you for its IP address. When you are done entering the list of servers, press Return on a blank `Server n name` field and enter `c` to continue configuring NIS on your system.

12. Indicate whether or not you want to allow `ypset` requests on your system.

It is best to disallow all `ypset` requests. Press Return to accept the default and confirm your choice.

13. Indicate whether or not you want your system to use all of the NIS databases served by the master server.

It is best to use all of the NIS databases.

If you choose to use all of the NIS databases, the `nissetup` script edits the `/etc/svc.conf` file to include the string `yp` for each database. It also edits the `/etc/passwd` and `/etc/group` files to include a plus sign followed by a colon (`+:`) at the end of each file. This enables your system to use NIS for each database listed. This symbol enables the file to be distributed by NIS. Continue with step 16.

If you choose not to use all of the NIS databases, enter `n` and continue with the next step.

14. Indicate whether or not you want to add `+:` to the end of the local `/etc/passwd` and `/etc/group` files.

For your system to use the NIS-served `passwd` database, `group` database, or both, `+:` must be the last line in the file or files you want NIS to serve. This applies to the `passwd` and `group` databases only.

Note

The service order selection for the `passwd` and `group` databases is handled by the Security Integration Architecture (SIA). If BSD is selected for `passwd` and `group` information in the `/etc/sia/matrix.conf` file, the `+` only is required for your system to search NIS.

15. Indicate whether or not you want the `nissetup` script to invoke the `svcsetup` script.

If you answer yes, the `nissetup` script invokes the `svcsetup` script, which allows you to modify the database services selection file (the `svc.conf` file). See Section 9.3.4 for information on modifying the `svc.conf` file.

If you answer no, the `nissetup` script continues. You must edit the `svc.conf` file later if you want your system to use NIS to obtain database information other than `passwd` and `group` information.

16. Indicate whether or not to start the NIS daemons automatically.

If you answer yes, `nissetup` starts the daemons.

If you answer no, use the following command to start the daemons manually after `nissetup` exits and returns you to the system prompt (`#`):

```
# /sbin/init.d/nis start
```

9.3.3 Configuring an NIS Client

To configure an NIS client, invoke the SysMan Menu as documented in Section 1.1.1 and do the following:

1. From the SysMan Menu, select Networking→Additional Network Services→Configure Network Information Service (NIS). SysMan Menu invokes the `nissetup` script.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman nis
```

2. A message reminds you that your network must be established before setting up NIS, and that in order to set up an NIS server you must have the Additional Networking Services subset installed. Enter `c` to continue.
3. Press Return following the script's explanation of `nissetup`, and then press Return again after the script explains the three types of systems in an NIS domain.
4. Enter and confirm your system's case-sensitive NIS domain name.

5. Press Return to accept the default that you are configuring a client.
6. Enter `c` to continue following the `nissetup` script's warning that at least one server must be configured for this domain.
7. Indicate whether or not you want to use the `-s` security option.
If you choose to run NIS with the `-s` option, the `ypbind` process runs in a secure mode. It is best to use this option.
8. Indicate whether or not you want to use the `-s` security option.
It is best to use this option. If you choose to run NIS with the `-s` option, you must enter the names of up to four NIS servers.
If you enter the name of a server that is not listed in the system's `/etc/hosts` file, the `nissetup` script prompts you for its IP address. When you are done entering the list of servers, press Return on a blank `Server n name` field and enter `c` to continue configuring NIS on your system.
9. Indicate whether or not you want to allow `ypset` requests on your system.
It is best to disallow all `ypset` requests. Press Return to accept the default, and confirm your choice.
10. Indicate whether or not you want your system to use all of the NIS databases served by the master server.
It is best to use all of the NIS databases.
If you choose to use all of the NIS databases, the `nissetup` script edits the `/etc/svc.conf` file to include the string `yp` for each database. It also edits the `/etc/passwd` and `/etc/group` files to include a plus sign followed by a colon (`+:`) at the end of each file. This enables your system to use NIS for each database listed. This symbol enables the file to be distributed by NIS. Continue with step 13.
If you choose not to use all of the NIS databases, enter `n` and continue with the next step.
11. Indicate whether or not you want to add `+:` to the end of the local `/etc/passwd` and `/etc/group` files.
For your system to use the NIS served `passwd` database, `group` database, or both, `+:` must be the last line in the file or files you want served by NIS. This applies to the `passwd` and `group` databases only.

Note

The service order selection for the `passwd` and `group` databases is handled by the Security Integration Architecture (SIA). If BSD is selected for password and group information

in the `/etc/sia/matrix.conf` file, only the `+` is required for your system to search NIS.

12. Indicate whether or not you want the `nissetup` script to invoke the `svcsetup` script.

If you answer yes, the `nissetup` script invokes the `svcsetup` script, which allows you to modify the database services selection file (the `svc.conf` file). See Section 9.3.4 for information on modifying the `svc.conf` file.

If you answer no, the `nissetup` script continues. You must edit the `svc.conf` file later if you want your system to use NIS to distribute database information other than password and group information.

13. Indicate whether or not to start the NIS daemons automatically.

If you answer yes, `nissetup` starts the daemons.

If you answer no, use the following command to start the daemon manually after `nissetup` exits and returns you to the system prompt (`#`):

```
# /sbin/init.d/nis start
```

9.3.4 Modifying the `svc.conf` File with `svcsetup`

If you choose not to use NIS for all of the default databases, you can edit the `/etc/svc.conf` file with the `svcsetup` script. If you answer yes when `nissetup` asks if you want to run `svcsetup`, it invokes the `svcsetup` script. Use the following procedure to edit the `/etc/svc.conf` file:

1. Press Return to choose the `m` option from the Configuration Menu.
2. Enter the numbers from the Change Menu that correspond to the databases whose entries you want to modify.
3. Enter the number that corresponds to the order in which you want to query the services on your system.

If you choose the default (2), the local `/etc` files are searched first for the requested information. If the information is not found locally, then an NIS server are queried. This choice is valid for all of the databases that NIS serves.

To have NIS serve `hosts` information if your system is also having `hosts` information served by DNS, choose either option 5 (`local,bind,yp`) or option 6 (`bind,local,yp`) for the `hosts` database. Note that options 3 (`local,bind`), 4 (`bind,local`), 5, and 6 are valid for the `hosts` database only.

9.3.5 Modifying or Removing an NIS Configuration

If you configure NIS and run the `nissetup` script, you can modify or remove the NIS configuration.

If you choose to modify the NIS configuration, the `nissetup` script proceeds as described in Section 9.3.1 to Section 9.3.3, resulting in a new configuration.

If you choose to remove the NIS configuration, the `nissetup` script prompts you to verify your choice, then removes the NIS information from the following files:

- `/etc/rc.config.common`
- `/etc/passwd`
- `/etc/group`
- `/etc/svc.conf`
- `/var/yp/DOMAIN` (where *DOMAIN* is the name of the current NIS domain)

This directory and its contents are deleted (for NIS master and slave servers only).

9.4 Managing an NIS Server

This section describes how to perform the following NIS server tasks:

- Add an NIS slave server to a domain
- Remove an NIS slave server from a domain
- Add a user to an NIS domain
- Update an NIS map
- Add an NIS map to a domain
- Remove an NIS map from a domain
- Modify the `/var/yp/Makefile` file
- Restrict access to NIS data

9.4.1 Adding an NIS Slave Server to a Domain

Adding a slave server to a domain enables the slave server to receive updated NIS maps from the master server and serve them to NIS clients in a domain.

To add an NIS slave server to a domain, do the following:

1. Set up the system as a slave server. See Section 9.3.2 for information on setting up a slave server.

2. Log in to the NIS master server as root.
3. Change to the `/var/yp` directory by using the `cd` command.
4. Undo the `ypservers` map and direct the output to a file by using the following command:

```
# makedbm -u domainname/ypservers > filename
```
5. Edit the file and add the host name of the slave server.
6. Build a new `ypservers` map by using the `makedbm` command as follows:

```
# makedbm filename ypservers
```

You can combine steps 4, 5, and 6 into one command line. See the example at the end of this procedure.
7. Move the `ypservers.dir` and `ypservers.pag` map files to the domain subdirectory.
8. Distribute the updated `ypservers` map to the slave servers by using the `yppush` command.
9. Edit the NIS master server's master `hosts` file and add an entry for the slave server, if it is not already in the `hosts` file. Then update the map by entering the `make` command. The `make` command also distributes the updated map.

See `makedbm(8)` for more information on building maps.

The following example (illustrating steps 3 through 9) shows how to add slave server `host8` to domain `market`:

```
# cd /var/yp
# /var/yp/makedbm -u market/ypservers ; echo host8\ 1
|/var/yp/makedbm - tmpmap
# mv tmpmap.dir market/ypservers.dir 2
# mv tmpmap.pag market/ypservers.pag
# yppush ypservers 3
# vi /var/yp/src/hosts 4
:
# make hosts 5
```

- 1 Represents the combination of steps 4, 5, and 6 in the preceding procedure. The output from the `makedbm` command with the `-u` option is displayed and the new server name, `host8`, is echoed on standard output to add it to the file. Then, the output is piped back into the `makedbm` command to build a new map named `tmpmap`.

Note

You can type these lines as one command even if the command wraps on your screen, or you can use the backslash escape character (`\`), as shown.

- ❷ Moves the `tmpmap.dir` and `tmpmap.pag` map files to the domain market subdirectory and renames them as `ypservers` map files.
- ❸ Distributes the updated map to the slave servers.
- ❹ Adds a new host to the `hosts` NIS map on the master server.
- ❺ Updates the map and distributes the updated map to the slave servers.

Section C.1 contains a sample script you can copy that performs the steps involved in adding a slave server to a domain. You still have to set up the slave server and edit the master server's `hosts` file, adding a slave server entry, if necessary.

9.4.2 Removing an NIS Slave Server from the Domain

Removing a slave server from a domain means that the system will no longer receive updated NIS maps from the master server and serve them to NIS clients in a domain.

To remove an NIS slave server from the domain, do the following:

1. Log in to the NIS slave server.
If the system will be an NIS client, configure it as an NIS client by using `nissetup`. See Section 9.3.3 for more information.
If the system will no longer use NIS, turn off the NIS configuration flag in the `/etc/rc.config.common` file by using the following command:

```
# /usr/sbin/rcmgr -c set NIS_CONF NO
```
2. Log in to the NIS master server as `root`.
3. Change to the `/var/yp` directory by using the `cd` command.
4. Undo the `ypservers` map and direct the output to a file by using the following command:

```
# makedbm -u ypservers > filename
```
5. Edit the file and remove the host name of the slave server.
6. Build a new map by using the `makedbm` command as follows:

```
# makedbm filename ypservers
```

You can combine steps 4, 5, and 6 into one command line. See the example following this procedure.

7. Move the `ypservers.dir` and `ypservers.pag` map files to the domain subdirectory.
8. Distribute the updated `ypservers` map to the slave servers by using the `yppush` command.

See `makedbm(8)` for more information on building maps.

The following example (illustrating steps 4 through 8) shows how to remove slave server `host4` from domain `market`:

```
# cd /var/yp
# /var/yp/makedbm -u market/ypservers | \ 1
  grep -v host4 | /var/yp/makedbm - tmpmap
# mv tmpmap.dir market/ypservers.dir 2
# mv tmpmap.pag market/ypservers.pag
# yppush ypservers 3
```

- 1 Represents the combination of steps 4, 5, and 6 in the preceding procedure. The output from the `makedbm` command with the `-u` option is piped into `grep` with the `-v` option to display all lines except the one containing the slave server name (`host4`). Then, the output is piped back into the `makedbm` command to build a new map named `tmpmap`.

Note

You can type these lines as one command even if the command wraps on your screen, or you can use the backslash escape character (`\`), as shown.

- 2 Moves the `tmpmap.pag` and `tmpmap.dir` map files to the domain `market` subdirectory and renames them as `ypservers` map files.
- 3 Distributes the updated map to the slave servers.

Section C.2 contains a sample script you can copy that performs the steps involved in removing a slave server from a domain. You still have to reconfigure the slave server as an NIS client or as a system that does not use NIS.

9.4.3 Adding a New User to an NIS Domain

Adding a new user to an NIS domain adds the user's account information to the `passwd` map and allows the user to participate in the NIS environment. A user has only one password on all systems that use NIS for their `passwd` map.

To add a new user to an NIS domain, invoke the SysMan Menu on the NIS master server, as documented in Section 1.1.1, and do the following:

1. From the SysMan Menu, select Accounts→Manage NIS Users to display the Manage NIS Users dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman nis_users
```

2. Select Add to display the Add a User dialog box.
3. Enter the user name, user ID, and password for the new user.
4. Select a primary group for the user:
 - a. Select Choose to open the Primary Group dialog box.
 - b. Select one group from the list of groups. Then, select OK to close the Primary Group dialog box.
5. Enter a secondary group for the user, if necessary.
6. Select a shell for the user.
 - a. Select Choose to open the Shells dialog box.
 - b. Select a shell from the pull-down menu. Then, select OK to close the Primary Group dialog box.
7. Deselect the Create Home Directory check box if you do not want the system to create a home directory for the user. By default, the system creates a directory for the user in the `/usr/users` directory.

If you choose to allow the system to create the user's home directory, you can specify an alternate location for the directory in the Home Directory field.
8. Enter comments for the account, if necessary. For example, at a college, you could use this field to indicate that a new account is temporary for a visiting professor.
9. Deselect the Lock Account check box to unlock the account. Unlocking the account gives the user permission to log in and use the account.
10. Select OK to create the user's account. You are informed that the account has been created. Select OK to dismiss the confirmation message and to close the Add a User dialog box.
11. Select Exit to close the Manage NIS Users dialog box.
12. Create the user's home directory if you did not allow the utility to create it for you. Then, set up the user's environment. See the *System Administration* guide for more information.

You can also modify and delete NIS users with the SysMan Menu. See the online help for more information.

If you prefer, you can use the `dxaccounts` or `useradd` utilities to administer NIS users. See the online help and `useradd(8)` for more information.

9.4.4 Adding a New Group to an NIS Domain

Adding a group to an NIS domain adds the group and all of its registered users to the `group` map. To add a new group to an NIS domain, invoke the SysMan Menu on the NIS master server, as documented in Section 1.1.1, and do the following:

1. From the SysMan Menu, select Accounts→Manage NIS Groups to display the Manage NIS Groups dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman nis_groups
```

2. Select Add to display the Add a Group dialog box.
3. Enter the group name and group ID for the new group.
4. Select one or more users who will be in the group from the Members list.
5. Select OK to create the group. You are informed that the group has been created. Select OK to dismiss the confirmation message and to close the Add a Group dialog box.
6. Select Exit to close the Manage NIS Groups dialog box.

You can also modify and delete NIS groups with the SysMan Menu. See the online help for more information.

If you prefer, you can use the `dxaccounts` or `groupadd` utilities to administer NIS groups. See the online help and `groupadd(8)` for more information.

9.4.5 Updating an NIS Map

Updating an NIS map involves making changes to an NIS map's master file, updating the `Makefile` file (if the map is not listed), and building and distributing the new map. Entries for the following standard maps are included in the `Makefile` file:

- `passwd`
- `group`
- `hosts`
- `networks`

- `rpc`
- `services`
- `protocols`
- `netgroup`
- `aliases` (`mail.aliases`)

The master files are located in `/var/yp/src` on the NIS master server.

To update an NIS map, do the following:

1. Log in to the NIS master server as root.
2. Change to the `/var/yp` directory by using the `cd` command.
3. Modify the `Makefile` file, if no entry exists in the `/var/yp/Makefile` file for the map you want to update.
See Section 9.4.8 for information on modifying the `Makefile` file.
4. Change to the `/var/yp/src` directory by using the `cd` command.
5. Edit the master file of the map you want to update and make your changes.
6. Change to the `/var/yp` directory by using the `cd` command.
7. Update and distribute the map by using the `make` command as follows:

```
# make map_name
```

The following example (illustrating steps 4 through 7) shows how to update the `hosts` map:

```
# cd /var/yp/src 1
# vi hosts 2
:
# cd /var/yp 3
# make hosts 4
```

- 1 Changes to the `/var/yp/src` directory.
- 2 Opens the `/var/yp/src/hosts` file for editing.
- 3 Changes to the `/var/yp` directory.
- 4 Updates the map and distributes it to the slave servers.

9.4.6 Adding an NIS Map to a Domain

Adding an NIS map to a domain allows the database information to be distributed throughout an NIS domain. You can create and distribute maps for any information you want to distribute.

To add an NIS map to a domain, do the following:

1. Log in to the NIS master server as root.
2. Create a master file for your new map.

A master file is an ASCII text file containing individual entries. Each entry has fields separated by spaces. Some of these fields are used to build a key to each entry. Review some of the master files in the `/var/yp/src` directory to better understand the structure of a master file.

3. If you are using NIS to distribute NFS Automount or AutoFS maps, create a file named `auto.master` in the `/var/yp/src` directory. If the file exists, add an entry for the map you want to distribute.

See Section 10.1.2 and Appendix B for more information on the `auto.master` map.

4. Edit `/var/yp/Makefile` file to include the new map in the default set of maps.

See Section 9.4.8 for information on modifying the `Makefile` file.

5. Change to the `/var/yp` directory by using the `cd` command.
6. Update the map by using the `make` command as follows:

```
# make map_name
```

The following example adds the `phonelist` map to a domain:

```
# vi /var/yp/src/phonelist 1
:
# vi /var/yp/Makefile 2
:
# cd /var/yp 3
# make phonelist 4
```

- 1 Creates a `phonelist` master file on the master server.
- 2 Opens the `Makefile` file for editing.
- 3 Changes to the `/var/yp` directory.
- 4 Updates the map and distributes the updated map to the slave servers.

9.4.7 Removing an NIS Map from a Domain

Removing an NIS map from a domain prevents the database information from being distributed throughout an NIS domain.

To remove an NIS map from a domain, do the following:

1. Log in to the NIS master server as root.

2. If you are using NIS to distribute NFS Automount or AutoFS maps, delete the entry for the map you no longer want distributed from the `auto.master` file in the `/var/yp/src` directory.

See Section 10.1.2 and Appendix B for more information on the `auto.master` map.

3. Edit the `/var/yp/Makefile` file to remove the map from the default set of maps.

See Section 9.4.8 for information on modifying the `Makefile` file.

9.4.8 Modifying the `/var/yp/Makefile` File

Modifying the `Makefile` file means adding or deleting database entries in the `/var/yp/Makefile` file on the NIS master server. By adding a database entry to the `Makefile` file, you indicate that you want a map produced for the specific database when you use the `make` command. By deleting a database entry, you indicate that you do not want a map produced for the specific database.

As you edit the `/var/yp/Makefile` file, remember the following:

- The order of entries in the line that begins with `all:` is not important. However, in continuation lines, the blank space preceding the line must be a tab character; do not use spaces.
- Variables are defined at the top of the `Makefile` file.

9.4.8.1 Adding an Entry

To add an entry to the `Makefile` file, do the following:

1. Log in to the NIS master server as root.
2. Edit the `/var/yp/Makefile` file and add the database name to the line beginning with `all:`. Next, add a line with the following format to the end of the file:

```
database_name:database_name.time
```

Finally, add an entry with the following format to the middle of the file:

```
database_name.time: various_commands
```

To simplify the creation of this entry, copy the `auto.home.time: entry` in the file and make the necessary database name changes.

3. If you are using NIS to distribute NFS Automount or AutoFS maps, uncomment any line that contains the `auto.master` string by deleting the comment character (`#`) that precedes it.

The following example shows the `phonelist` database added to the `/var/yp/Makefile` file. There is a tab character preceding the `netgroup` database name in the `all:` line.

```
all: passwd group hosts networks rpc services protocols \
    netgroup aliases phonelist
    :
$(YPDBDIR)/$(DOM)/phonelist.time: $(DIR)/phonelist
    -@if [-f $(DIR)/phonelist ]; then \
        $(SED) -e "/^#/d" -e s/#.*$$// $(DIR)/phonelist | \
        $(MAKEDBM) -a $(METHOD) - $(YPDBDIR)/$(DOM)/phonelist; \
        $(TOUCH) $(YPDBDIR)/$(DOM)/phonelist.time; \
        $(ECHO) "updated phonelist"; \
        if [ ! $(NOPUSH) ]; then \
            $(YPPUSH) phonelist; \
            $(ECHO) "pushed phonelist"; \
        else \
            : ; \
        fi \
    else \
        $(ECHO) "couldn't find $(DIR)/phonelist"; \
    fi
    :
phonelist: phonelist.time
```

9.4.8.2 Deleting an Entry

To delete an entry from the `Makefile` file, do the following:

1. Log in to the NIS master server as `root`.
2. Edit the `/var/yp/Makefile` file, delete the database name from the line beginning with `all:`, and delete the line beginning with the database name (`database_name:`).

Instead of deleting the database line, you could comment out the line by adding a comment character (`#`) to the beginning of the line.

9.4.9 Restricting Access to NIS Data

By default, the `ypserv` and `ypxfrd` daemons provide NIS information to anyone with network access to an NIS server who makes a request. However, you can restrict NIS database access to only those hosts in subnets you specify by completing the following steps:

1. Log in to the NIS server as `root`.
2. Create a `/var/yp/securenets` file.

3. Edit the `/var/yp/securenets` file and add an entry for each subnet from which the NIS server is to accept NIS requests. The format of each file entry is as follows:

```
subnet_mask subnet_ip_address
```

For example:

```
255.255.0.0 128.30.0.0 1
255.255.255.0 128.211.10.0 2
255.255.255.255 128.211.5.6 3
```

- 1 Allows IP addresses that are within the subnet 128.30 range to access the NIS files. The network mask is 255.255.0.0 and the corresponding network address is 128.30.0.0.
- 2 Allows IP addresses that are within the subnet 128.211.10 range to access the NIS files.
- 3 Allows one host with the IP address 128.211.5.6 to access the NIS files.

4. Save the file.

If the file does not exist or contains no entries, the server accepts any NIS request.

If the file exists and contains entries, the `ypserv` and `ypxfrd` daemons read the `/var/yp/securenets` file during initialization. When an NIS request is received, the requester's IP address is compared to the subnets in the `/var/yp/securenets` file. If it matches, the request is processed. If it does not match, NIS silently discards the request. No message is logged (because malicious users could use these messages to fill up a system's disk).

On the system making the NIS request, NIS commands such as `ypcat` terminate with no error message. If a user is trying to log in to a system, the login times out after many retries.

Note

If the `/var/yp/securenets` file is modified, you must kill and restart the `ypserv` and `ypxfrd` daemons.

You can also use a `/var/yp/securenets` file to restrict access to NIS data on a slave server. However, the NIS slave server's IP address must be in the authorization range of entries in the `/var/yp/securenets` file of the NIS master.

9.5 Managing an NIS Client

This section describes how to perform the following NIS client management tasks:

- Change an NIS password
- Obtain NIS map information

9.5.1 Changing an NIS Password

To change a user's password in the NIS `passwd` map, use the `yppasswd` command. If you receive an error message, ask the system administrator on the master server to verify that the `rpc.yppasswdd` daemon on the NIS master server is running.

If you try to change an NIS-distributed password with the `passwd` command, you receive the following error message:

```
Not in passwd file.
```

The root password is local and not in the NIS file. To change the root password, use the `passwd` command.

See `yppasswd(1)` and `rpc.yppasswdd(8)` for further information.

9.5.2 Obtaining NIS Map Information

NIS map information includes the following:

- Map names
- Map values
- Map keys
- Map master server

To obtain NIS map information, issue one of the commands listed in Table 9-1.

Table 9-1: NIS Map Information Commands

Command	Action
<code>ypcat</code>	Prints values from an NIS database
<code>ypwhich</code>	Prints the name of the host that is the current NIS server or map master
<code>ypmatch</code>	Prints the values of one or more keys from an NIS map

Use the `-x` option with any of the commands shown in Table 9-1 to list all the map nicknames.

See `ypcat(1)`, `ypwhich(1)`, and `ypmatch(1)` for more information about these commands.

The following command lists all available maps and their master servers:

```
# ypwhich -m
```

The following command lists all values in the `hosts` map:

```
# ypcat hosts
```

The following command lists all occurrences in the `hosts` map that have the key `apple`:

```
# ypmatch apple hosts
```

The following command lists all occurrences in the `hosts` map that have the name `jones` associated with them. The name `jones` is not a key in this map.

```
# ypcat hosts | grep jones
```

10

Network File System

The Network File System (NFS) is a facility for sharing files in a heterogeneous environment. This chapter describes:

- The NFS environment
- How to configure your system for NFS
- How to manage NFS servers and clients

For introductory information on NFS, see `nfs_intro(7)`. For troubleshooting information, see Section 15.12 for clients and Section 15.11 for servers.

10.1 NFS Environment

In the NFS environment, systems can have the following roles:

- Client — A system that imports file systems. A client can mount file systems by using either the `/etc/fstab` file or an automatic mounting daemon, such as the `automount` or `autofs` daemons. All methods are explained in this chapter.
- Server — A system that exports file systems.

Your system can be set up as an NFS server, a WebNFS server, an NFS client, or all three.

10.1.1 Distributing the hosts Database

If your network is running the Network Information Service (NIS) or the Domain Name System (DNS) to distribute host information, you do not need to list each server that is referenced in a client's `/etc/fstab` file in the client's local `/etc/hosts` file. However, the server's host information must be in the NIS or DNS database.

Similarly, if your network is running NIS or DNS to distribute host information and the client information is listed in the `hosts` database, you do not have to list each client that is referenced in a server's `/etc/exports` file in the server's local `/etc/hosts` file.

10.1.2 Automatic Mounting Daemons

The `automount` and `autofs` daemons offer alternatives to mounting remote file systems with the `/etc/fstab` file, allowing you to mount them on an as-needed basis.

When a user on a system running one of these daemons invokes a command that must access a remotely mounted file or directory, the daemon mounts that file system or directory and keeps it mounted for as long as the user needs it. When a specified amount of time elapses (the default is 5 minutes) without the file system or directory being accessed, the daemon unmounts it.

You specify the file systems to be mounted in map files. These maps may be customized to suit your environment and administered in the following ways:

- Use NIS to create and distribute the maps
- Administer the maps locally
- Use a combination of both methods

See Appendix B for information on creating these maps. Note that with a few restrictions, as documented in the Restrictions section of `autofs`(8), Automount and AutoFS maps can be used interchangeably.

10.1.2.1 Serving Automount and AutoFS Maps with NIS

NIS allows you to create and distribute customized Automount and AutoFS maps. When NIS is used to distribute maps, the administrator of the NIS master server creates and administers the maps for the NIS domain. In this case, you must configure each system that uses Automount or AutoFS as an NIS client so that it can receive the maps.

If many clients in an environment remotely mount the same file system by specifying it in their `/etc/fstab` file, that file system is a good candidate for inclusion in a map distributed by NIS. Carefully constructed maps can allow client systems to eliminate a large part of their `/etc/fstab` files. If the location of a file system that is included in a distributed map changes, or its server changes, the administrator changes the map on the NIS master server. The change is then propagated throughout the domain without users on the client systems having to edit their `/etc/fstab` files.

See Section 9.3.1 for information on configuring a master NIS server to serve maps.

10.1.2.2 Local Automount and AutoFS Maps

Local Automount and AutoFS maps might be useful to you under the following circumstances:

- Your system mounts remote file systems that are not typically mounted by other NIS clients.
- Your network is not running NIS.
- You need to test a map.

Administering the `automount` or `autofs` daemons locally is the same as administering them when NIS distributes the maps, except that you, as administrator of your system, create and manage the maps.

A local `auto.master` map serves the same function as one distributed in an NIS domain. If you specify a local `auto.master` map, the daemon consults it for the location of other maps, their local mount points, and the mount options. You can use an `auto.master` map that is distributed by NIS, a local `auto.master` map, both, or neither, if the selected daemon is invoked correctly.

10.1.2.3 WebNFS

WebNFS is an NFS protocol that allows clients to access files over the Internet in the same way that local files are accessed. WebNFS uses a public file handle that allows it to work across a firewall. This public file handle also reduces the amount of time required to initialize a connection. The public file handle is associated with a single directory (`public`) on the WebNFS server. See `exports(4)`, `exportfs(2)`, and `nfs_intro(4)` for further information.

10.2 Planning NFS

Figure 10–1 shows the NFS Setup Worksheet, which you can use to record the information required to configure NFS. If you are viewing this manual online, you can use the print feature to print a copy of this worksheet. The following sections explain the information you need to record on the worksheet.

Figure 10–1: NFS Setup Worksheet

NFS Setup Worksheet			
Server			
Number of nfsd threads:	TCP: _____	UDP: _____	
Property lists:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	
NFS locking:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	
PC-NFS daemon:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	
Allow nonroot mounts:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	
Address verification:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	
Exported directories:			
Path name:	Permissions:	Network group/ Node name:	
_____	_____	_____	
_____	_____	_____	
_____	_____	_____	
_____	_____	_____	
_____	_____	_____	
Client			
Number of I/O threads:	_____		
NFS locking:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	
Automatic mounting daemon:	<input type="checkbox"/> Automount	<input type="checkbox"/> AutoFS	<input type="checkbox"/> None
Imported directories:			
Path name:	Remote server name:	Local mount point:	RO:
_____	_____	_____	<input type="checkbox"/>
_____	_____	_____	<input type="checkbox"/>
_____	_____	_____	<input type="checkbox"/>
_____	_____	_____	<input type="checkbox"/>
_____	_____	_____	<input type="checkbox"/>

10.2.1 Server

Number of nfsd threads

Enter the number of `nfsd` TCP and UDP server threads to run. These threads service requests from NFS clients. The default number of 8 is adequate for an average work load. You can configure a combined total of 0 to 128 TCP and UDP server threads.

On systems that support Cache Coherent NUMA, the number of threads is per Resource Affinity Domain (RAD). See `nfsd(8)` and `numa_intro(3)` for more information.

Property lists

If you want to run the property list daemon, check Yes; otherwise, check No. The property list daemon allows the server to handle requests to get, set, or delete the property lists associated with NFS-served file system objects. See `proplistd(8)` and `proplist(4)` for more information.

NFS locking

If you want to run the NFS lock manager (`rpc.lockd`) and status monitor (`rpc.statd`), check Yes. Running these daemons allows users to use `fcntl(2)` and `lockf(3)` to lock file regions on NFS files (in addition to local files). If you do not run these daemons, users can use advisory locking primitives only on local files.

PC-NFS daemon

If you want to run the PC-NFS daemon (`rpc.pcnfsd`), check Yes; otherwise, check No. The PC-NFS daemon allows the server to handle NFS requests from PCs.

Allow nonroot mounts

If you allow nonroot mounts, users on client systems who do not have root privileges can still mount the file systems or directories exported from this system. If you do not allow nonroot mounts, only the superusers on the client systems can mount file systems from this host. The default setting does not allow nonroot mounts.

Address Verification

If you want the server to verify the Internet address of any host that requests an exported directory, check Yes; otherwise, check No. If you choose Yes and you also want to verify that the host is in the server's domain or subdomain, check Domain Checking, Subdomain Checking, or both.

10.2.1.1 Exported Directories

Use the following fields to define file systems that your server will export to client systems:

Path name

The path name of the file systems or directories that you intend to export.

Permissions

The permissions to assign for each exported file system or directory. You can specify whether a file system or directory is exported with read-write (rw) or read-only (ro) permission, and you can map client superuser access to a root user ID (UID) number other than the default of -2. If you have a WebNFS server with the `-public` option set, the mount access list is ignored by the server so that all hosts using the WebNFS protocol have access to this directory. For more information on assigning permissions to exported file systems or directories and on specifically mapping the root UID for clients, see `exports(4)`.

Network group/Node name

The network groups or individual host names to which you will export these file systems or directories. If you want to limit the hosts that can import a file system or directory, you must explicitly specify the individual hosts or network groups in the `/etc/exports` file. If you do not specify individual hosts or network groups, all hosts can import that file system or directory. For information on defining network groups, see `netgroup(4)`.

10.2.2 Client

Number of I/O threads

The number of I/O threads to run. The default number of 7 is recommended for optimum load generation on servers. You can configure from 0 to 64 `nfsiod` threads.

In addition, you can start `nfsiod` threads from the command line. See `nfsiod(8)` for information on starting `nfsiod` threads from the command line.

NFS locking

If you want to run the NFS lock manager (`rpc.lockd`) and status monitor (`rpc.statd`), check Yes. Running these daemons allows users to use `fcntl(2)` and `lockf(3)` to lock file regions on NFS files (in addition to local files). If you do not run these daemons, users can use advisory locking primitives only on local files.

Automatic mounting daemon

If the client is to run an automatic mounting daemon, such as Automount or AutoFS, check the box for one of these daemons; otherwise, check None.

You can select only one automatic mounting daemon. While AutoFS provides higher efficiency and availability than Automount, there are some restrictions for its use. See the Restrictions sections of `autofs(8)` and `autofs(8)` for more information.

If the network is running the NIS, the Automount or AutoFS maps are better administered and served from the NIS master server. The format of the maps is the same whether they are local or served by the NIS master server. For information on creating maps, see Appendix B.

10.2.2.1 Imported Directories

Use the following fields to define the remote file systems that your client will import:

Path name

The complete pathnames of the file systems or directories that you want to import.

Remote server name

The host names of the servers from which you are importing file systems or directories.

Local mount point

The mount point on the local system where you want the imported file systems or directories to reside.

RO (Read-only)

The permissions for the imported file systems or directories. Check the box for a read-only mount. Leave the box unchecked for a read-write mount.

Note

If you mount your user area from a server, make sure that your UID on the client is the same as your UID on the server. NFS uses your client UID to check against file access permissions on the server. If your UID is different on the client and server, you cannot modify your own NFS mounted files (assuming that you have the permissions on the mounted files set so that only you can modify them). Since the server does the access checking, the only UID allowed to modify the files is the one that the server knows.

10.3 Configuring NFS

Use the SysMan Menu application of the Common Desktop Environment (CDE) Application Manager to configure NFS on clients and servers. To invoke the SysMan Menu application, follow the instructions in Section 1.1.1.

10.3.1 Configuring an NFS Server

To configure an NFS server, complete the following steps. If you want your system to import file systems, see Section 10.3.2 for information on configuring an NFS client.

1. From the SysMan Menu, select Networking→Additional Network Services→Network File System (NFS)→Configure system as an NFS server to display the Configure NFS Server dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman nfs_server
```

2. Enter the number of server TCP threads to be run in the appropriate field.
3. Enter the number of server UDP threads to be run in the appropriate field.
4. Select the Enable Property List Daemon check box if you want to run the property list daemon (`proplistd`).
5. Deselect the Enable Locking check box if you do not want to run the NFS lock manager (`rpc.lockd`) and status monitor (`rpc.statd`) daemons. Locking is enabled by default.
6. Select the Enable PC-NFS Daemon check button if you want to run the `rpc.pcnfsd` daemon.

If you run the PC-NFS daemon, you must export to the client the directories you want to mount on the PC client. To enable the client to utilize network printing, you must export the `/usr/spool/pcnfs` directory to the PC client. For information on exporting directories, see Section 10.5.2.

7. Select the Allow Nonroot Mounts check box if you want to allow users other than root to mount file systems.
8. Deselect the Internet Address Verification check box if you do not want the `mountd` daemon to verify the IP address of each host requesting a mount or unmount. Internet Address Verification is enabled by default.
9. Select the Internet Address Verification & Domain Checking check box to have the `mountd` daemon verify that the host requesting a mount or unmount is in the server's domain.

10. Select the Internet Address Verification & Subdomain Checking check box to have the `mountd` daemon verify that the host requesting a mount or unmount is in the server's subdomain.
11. Specify the directories you want to export by following steps 2 through 7 in Section 10.5.2.
12. Select OK to validate your changes. The utility prompts you to start the NFS daemons.
13. Select Yes to save your configuration, start the daemons, and apply the changes immediately; or select No to save your configuration, close the Configure NFS Server dialog box, and apply the changes the next time you reboot your system.

If you choose Yes, you are informed that the NFS daemons have been started. Select OK to dismiss the message and to close the Configure NFS Server dialog box.

You can also modify or deconfigure your server configuration after the initial setup. See the online help and Section 10.4 for more information.

10.3.2 Configuring an NFS Client

To configure an NFS client, do the following:

1. From the SysMan Menu, select Networking→Additional Network Services→Network File System (NFS)→Configure system as an NFS client. The Configure NFS Client dialog box is displayed.
Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman nfs_client
```
2. Enter the number of client I/O threads to be run in the appropriate field.
3. Select the Enable Locking check box to specify locking configuration if the status of the `lockd` daemon is Stopped. If the status of the daemon is Running, locking is already set.
4. Select the Enable Automount Daemon check box to configure the `automount` daemon. See Section 10.1.2 for information on Automount and Appendix B for information on Automount maps. If you would like to configure the AutoFS daemon, see Section 10.6.2.2 for more information.
5. Enter appropriate arguments to the `automount` daemon in the Automount Arguments field. See Section 10.6.2.3 for more information.
6. Specify the directories you want to import, those not already imported by `automount`, by following steps 2 through 10 in Section 10.6.1.

7. Select OK to validate the changes. (Due to the myriad of `automount` arguments available to the user, the validation of these arguments is deferred until the `automount` daemon starts and verifies them.)

You are asked if you would like to start or restart the NFS daemons.

8. Select Yes to save the configuration, start the daemons, and apply your changes immediately; or select No to save the configuration, close the Configure NFS Client dialog box, and apply the changes the next time you reboot your system.

If you choose Yes, you are informed that the NFS daemons have been started. Select OK to dismiss the message and to close the Configure NFS Client dialog box.

You can also modify or deconfigure your client configuration after the initial setup. See the online help and Section 10.4 for more information.

10.4 Deconfiguring NFS

You can use the SysMan Menu to deconfigure NFS servers and clients. When you deconfigure an NFS server or an NFS client, the corresponding NFS daemons stop and all of the corresponding NFS configuration information is deleted from the system. This action cannot be undone. To restore your NFS server or client, you must configure it again using the SysMan Menu.

When you deconfigure an NFS server, the client services are not removed. Likewise, when you deconfigure an NFS client, the server configuration is not removed. If you would like to deconfigure both the client and server configurations on a system, you must perform each action independently.

To deconfigure an NFS server, select Deconfigure system as an NFS Server from the SysMan Menu, or enter the following command on the command line:

```
# /usr/sbin/sysman nfs_deconfig_server
```

To deconfigure an NFS client, select Deconfigure system as an NFS Client from the SysMan Menu, or enter the following command on the command line:

```
# /usr/sbin/sysman nfs_deconfig_client
```

For both client and server, the Deconfigure NFS dialog box is displayed. Select Yes to deconfigure the service. You are informed that the service has been deconfigured. Select OK to dismiss the message and to close the dialog box.

10.5 Managing an NFS Server

This section describes how to perform the following NFS server tasks:

- Export a directory or file system
- Halt export of a directory or file system
- Enable a superuser on a client system to access files as superuser
- Send mail to superuser (root) across NFS
- Enable port monitoring
- Monitor the NFS load

10.5.1 Export Guidelines

The `/etc/exports` file defines an export list for each file system and directory that a client can mount. When creating entries in the `/etc/exports` file, remember the following:

- Make only one entry for each exported file system or directory; multiple entries are not supported.
- Each entry exports that directory and all subdirectories in it, except for those subdirectories that reside in a file system (disk partition) different from the exported directory.
- File systems and directories are exported with read-write access by default.
- If no remote system (client) names are specified for a file system or directory, any client on the network can mount that file system or directory.
- If one or more client names are specified for a file system or directory, only those clients can mount the exported file system or directory.
- If you start the `mountd` daemon with the `-i` option, only those hosts in the server's host database are allowed mount access. If you start the `mountd` daemon with the `-d` or `-s` option, only those clients in the same domain or subdomain, respectively, are allowed mount access.
- Exporting specific directories to specific clients provides more security than does exporting an entire file system to all clients.
- Protect sensitive exported data on the server by making the data files owned and accessible only by root, and do not allow superusers on client systems root access over NFS.
- The `-public` option can only be specified by one exported file system.

10.5.2 Exporting a File System or Directory

Exporting a file system or directory makes it available for client systems on the network to mount remotely. If you want your system to be an NFS server and to export file systems and directories, be aware that your system will be less secure. However, depending on how you export your files, you can minimize the security risks.

To export a file system by using the SysMan Menu, do the following:

1. From the SysMan Menu, select Networking→Additional Network Services→Network File System (NFS)→Configure system as an NFS server to display the Configure NFS Server dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman nfs_server
```

2. Select the Shared Local Directories button to display the Share Local Directory dialog box.
3. Select Add to add a shared directory. The Add/Modify dialog box is displayed.
4. Enter the full path name of the directory to be exported in the Share this Directory field.
5. Select whether the directory has read/write or read-only access and whether all hosts or only selected hosts can have access. By default, the directory is exported with read/write permissions to all hosts.
If you choose Selected in either the Read/Write or Read-Only dialog box, enter the name of each host that can have access to this directory in the appropriate field. Select Add for each host.
6. Select OK to validate the entry and to close the Add/Modify dialog box. Repeat steps 3 through 6 for additional directories.
7. Select OK to save the list of directories you chose to export in the `/etc/exports` file. You are informed that the changes have been made. Select OK to dismiss the message and to close the Share Local Directory dialog box.
8. Select OK to close the NFS Server dialog box.

You can also modify and delete exported directories with the Share Local Directory dialog box. See Section 10.5.3 and the online help for more information.

Optionally, you can use a text editor to add, modify, and delete exported directories directly in the `/etc/exports` file. See the `exports(4)` reference page for more information about editing this file.

10.5.3 Halting Export of a Directory or File System

Halting export of a directory or file system prevents client systems from accessing the particular directory or file system; you can still export other directories or file systems. If you do not want to export any file systems, you might want to deconfigure your NFS server as documented in Section 10.4.

To halt the export of a file system by using the SysMan Menu, do the following:

1. From the SysMan Menu, select Networking→Additional Network Services→Network File System (NFS)→Configure system as an NFS server to display the Configure NFS Server dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman nfs_server
```

2. Select the Shared Local Directories button to display the Share Local Directory dialog box.
3. Select the entry that you no longer want to export from the list of shared directories.
4. Select Delete to remove the highlighted entry from the list. Repeat steps 3 and 4 to halt the export of additional entries.
5. Select OK to save the remaining list of exports in the `/etc/exports` file. You are informed that the changes have been made. Select OK to dismiss the message and to close the Share Local Directory dialog box.
6. Select OK to close the NFS Server dialog box.

You can also add and modify exports with the Share Local Directory dialog box. See Section 10.5.2 and the online help for more information.

Optionally, you can use a text editor to add, modify, and delete exports directly in the `/etc/exports` file. See the `exports(4)` reference page for more information about editing this file.

10.5.4 Enabling Client Superuser Access to Files

By default under NFS, a superuser (root) on a client system does not have superuser privileges on the server and cannot do the following:

- Access remotely mounted files and directories whose permissions do not allow world access
- Change the ownership of remotely mounted files (run the `chown` command)

For security reasons, it is best not to allow a remote superuser access to your system as superuser unless both the remote host and superuser are

trusted. However, in a friendly network environment, you can explicitly allow superuser access over the network.

To allow a superuser on a client access to your server system, edit the `/etc/exports` file on your server and add the `-root=0` option to the entry you want to make available. The `-root=0` option maps the remote superuser's identification to UID 0. All future mount requests will be honored with root mapping. By default, this option allows superuser access from any client system on the network. To restrict the superuser access to specific systems, use the `-root=host_list` option, where `host_list` is a list of host names. See `exports(4)` for more information.

By default, NFS servers regard superusers and those users without UNIX authentication (personal computer systems) as anonymous users. This class of users can only access files that are accessible to the world. To prevent anonymous users from accessing file systems or directories, use the `-anon=-1` option. If you still want to allow client superusers access to the file systems or directories, specify the `-root` option in addition to the `-anon` option. The `-root` option overrides the `-anon` option for client superusers only.

A superuser on a client system can assume the identity of any other user on the client system by substituting the UID number. The client superuser could then have the access rights of another user on the server. Therefore, to protect sensitive exported data on the server, make root the owner of the data files and do not export the directory or file system with root mapping. This is useful if you need to export other files in the file system.

The following example shows entries in an `/etc/exports` file:

```
/usr/games -root=0 host8 1  
/usr/templates -root=host8 2
```

- 1 Exports the `/usr/games` file system. It can be mounted remotely (read-write) only by the client system `host8`. However, the client superuser has superuser access to the file system. The superuser's UID is 0 (zero).
- 2 Exports the `/usr/templates` file system. It can be mounted remotely (read-write) by any client in the network. However, only the superuser on `host8` has superuser access to the file system.

10.5.5 Sending Mail to Superuser (root) Across NFS

If the `/usr/spool/mail` directory is remotely mounted from the server, and the directory is not exported with the `root=0` option, client users will not be able to send mail to the superuser (root) on the server. To enable clients to send mail to root, set the root and admin aliases to the login name or names

of the system administrators for that system. Then, users can address all mail intended for the administrators of that system as follows:

```
admin@system
```

To enable clients to send mail to root, follow these steps:

1. Edit the `/var/adm/sendmail.cf` file and add the alias name `admin` to the following line:

```
CN MAILER-DAEMON postmaster
```

The resulting line will look like the following line:

```
CN MAILER-DAEMON postmaster admin
```

This adds the name `admin` to the class `N`.

Alternatively, you can run the Mail Configuration application and add `admin` as a local user. See Chapter 13 for more information.

2. Edit the `/var/adm/sendmail/aliases` file, add the login names of the system administrators, and redefine (alias) the name `root` to be `admin`.
3. Restart the `sendmail` daemon by using the following command:

```
# /sbin/init.d/sendmail restart
```

If you are enabling clients to send mail to root, remember the following:

- It is best for all systems in the local area network (LAN) to follow this convention. Mail for `root` or `admin` on any system can be automatically directed to any user login on any system.
- A `/usr/spool/mail/root` mailbox is not created or used.

The following example shows the steps involved in enabling clients to send mail to root.

```
# vi /var/adm/sendmail/sendmail.cf 1
:
# vi /var/adm/sendmail/aliases 2
:
# /sbin/init.d/sendmail restart 3
```

- 1 Opens the `/var/adm/sendmail/sendmail.cf` file to add the `admin` alias.
- 2 Opens the `/var/adm/sendmail/aliases` file to add the login names and `root` alias.
- 3 Restarts the `sendmail` daemon.

The following example shows entries in the `/var/adm/sendmail/aliases` file for the system administrators `John`, `Mary`, and `Joe`:

```
admin:john,mary,joe
root:admin
```

10.5.6 Enabling Port Monitoring

Only privileged users can attach to Internet domain source ports known as privileged ports. By default, NFS does not check to see if a client is bound to a privileged port. You might want to activate NFS server port monitoring to be sure that file access requests were generated by the client kernel rather than forged by an application program.

Although this operating system enforces the privileged port convention, some operating systems do not. If hosts running a different operating system are on your network, activating port checking might not improve security, but could prevent those systems from functioning properly as NFS client systems.

To start NFS server port monitoring, enter the following command:

```
# /usr/sbin/nfsportmon on
```

To stop source port monitoring, enter the following command:

```
# /usr/sbin/nfsportmon off
```

10.5.7 Monitoring the NFS Load

Monitoring the NFS load allows you to see the number of NFS requests, both client and server, being executed on the local machine. It is a good idea to monitor NFS requests periodically to determine whether you need additional NFS server threads.

To monitor NFS requests, use the `nfsstat` command with the following syntax:

nfsstat -n

See `nfsstat(8)` for more information on monitoring NFS load.

The following example shows the client and server activity on a local machine:

```
# /usr/bin/nfsstat -n
nfs:
calls      badcalls
69228      0

Server nfs V2:
null      getattr  setattr  root      lookup    readlink  read
1 0%      24 0%    0 0%      0 0%      60 0%    0 0%      5 0%
wrcache   write    create    remove    rename    link      symlink
0 0%      58030 83%  20 0%     0 0%      0 0%     0 0%     0 0%
mkdir     rmdir    readdir  statfs
0 0%      0 0%     0 0%      2 0%
```

```

Server nfs V3:
null      getattr  setattr  lookup    access    readlink  read
0 0%      667 0%   1009 1%   2598 3%   101 0%   200 0%   1408 2%
write     create   mkdir    symlink   mknod    remove    rmdir

10.6 Managing an NFS Client

Your system can be an NFS client if the following conditions exist:

- Your system can reach an NFS server over the network.
- Your system's host or network group name is included in the server's `/etc/exports` file, or the server is exporting a file system to all systems on the network.

This section describes how to perform the following NFS client tasks:

- Mount a remote file system or directory
- Mount a remote file system or directory with Automount or AutoFS
- Unmount a remote file system or directory

10.6.1 Mounting a Remote File System or Directory

You can mount a remote file system or any subdirectory within a remote file system onto a local mount point. While mounted, it is treated as a file system by the local system.

To mount a remote file system or directory by using the SysMan Menu, do the following:

1. From the SysMan Menu, select Networking→Additional Network Services→Network File System (NFS)→Configure system as an NFS client to display the Configure NFS Client dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman nfs_client
```

2. Select the Mount Network Directories button to display the Mount Network Directory dialog box.
A list of NFS-mounted directories that are saved in the `/etc/fstab` file is displayed. Remote file systems that you mounted by using the `mount` command are not included in this list.
3. Select Add to add a remote directory. The Add/Modify dialog box is displayed.
4. Enter the host name of the NFS server from which the remote directory is exported in the Remote Host Name field.
5. Enter the full path name of the directory to be imported in the Remote Directory Path field.
6. Enter the full path name of the local directory on which the imported directory is to be mounted in the Local Mount Point field.
7. Select whether the directory has read-only or read/write access with the appropriate radio button.
8. Select the Mount on Reboot checkbox if you want the directory to be mounted each time you reboot.
9. Select OK to validate the entry and to close the Add/Modify dialog box. Repeat steps 3 through 9 for additional directories.
10. Select OK to save the list of directories you chose to import. The names of those directories that are to be mounted on reboot are saved in the `/etc/fstab` file.
You are informed that the changes have been made. Select OK to dismiss the message and to close the Mount Network Directory dialog box.
11. Select OK to close the NFS Client dialog box.

You can also modify and delete your imported directories with the Mount Network Directory dialog box. See Section 10.6.3 and the online help for more information.

Each directory imported via the Mount Network Directory dialog box is mounted using the `bg` and `hard` options of the `mount` command. If the first attempt to mount the directory fails, the client tries mounting it in the

background (`bg` option), and it continues attempting to mount the directory until the server responds (`hard` option). No other `mount` options can be selected via the dialog box.

Optionally, you can use the `mount` or `umount` commands to mount or unmount remote file systems from the command line. Or, you can use a text editor to directly add, modify, or delete entries in the `/etc/fstab` file. You would use these alternatives if you need to specify `mount` options that are not supported by the Mount Network Directory dialog box. See `mount(8)`, `umount(8)`, and `fstab(4)` for more information.

10.6.2 Automatically Mounting a Remote File System

The following sections describe how to configure Automount and AutoFS, two daemons that allow you to automatically mount a remote file system or directory at the time of access.

Before starting the configuration procedure for either daemon, determine whether you are using local maps or NIS-distributed maps. See Section 10.1.2 for a description of local and NIS-distributed maps.

10.6.2.1 Using Automount to Mount a Remote File System

To use local Automount maps, do the following:

1. Log in as root.
2. Create a local `auto.master` map. You can create this and other maps in any directory on the system, but they are conventionally located in the `/etc` directory, where the SysMan Menu expects to find them.

See Appendix B for information on creating maps.

Note

If you are modifying an existing `auto.master` map, you must stop and restart the `automount` daemon to apply the revised map.

3. Create the local maps for your system.
4. Start the `automount` daemon by using the NFS Client dialog box of the SysMan Menu. See Section 10.3.2 for information on starting the `automount` daemon.

When the `automount` daemon starts, it uses the local `auto.master` file to determine the location of other maps, their local mount points, and the mount options.

To use NIS-distributed Automount maps, do the following:

1. Set up your system as an NIS client. See Section 9.3.3 for information on setting up an NIS client.
2. Start the `automount` daemon by using the NFS Client dialog box of the SysMan Menu. See Section 10.3.2 for information on starting the `automount` daemon.

The NIS master server serves all Automount maps in the domain. When the `automount` daemon starts, it uses the master `auto.master` file to determine the location of other maps, their local mount points, and the mount options.

If you alter your local or NIS-distributed Automount maps at any time, you must restart the `automount` daemon on clients as follows to apply the changes:

1. From the SysMan Menu, select Networking→Additional Network Services→Network File System (NFS)→Configure system as an NFS client to display the Configure NFS Client dialog box.
Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman nfs_client
```
2. Deselect the Enable Automount check box.
3. Select OK to disable Automount and Yes to restart the NFS daemons. A message indicates the the daemons are restarted; select OK to dismiss the message and close the NFS Client dialog box.
4. Open the NFS Client dialog box again.
5. Select the Configure for Automount check box.
6. Select OK to enable Automount and Yes to restart the NFS daemons. A message indicates the the daemons are restarted.
7. Select OK to dismiss the message and to close the NFS Client Setup dialog box.

See `automount(8)` for information on the `automount` command and its arguments.

10.6.2.2 Using AutoFS to Mount a Remote File System

If you currently use Automount to mount remote file systems, and you are switching to AutoFS, see `autofs(8)` and `autofsmount(8)` for information about features and restrictions that are specific to AutoFS. Note that Automount and AutoFS maps are compatible, with the few exceptions that are mentioned in Restrictions section of `autofsmount(8)`.

To use local AutoFS maps, do the following:

1. Log in as root.
2. Create a local `auto.master` map. You can create this and other maps in any directory on the system, but they are conventionally located in the `/etc` directory.

See Appendix B for information on creating maps.

Note

If you are modifying an existing `auto.master` map, you must process the map with the `autofs mount` command to apply the changes.

3. Create the local maps for your system.
4. Start the `autofs d` daemon by entering the following command:

```
# /usr/sbin/autofs d &
```
5. Execute the `autofs mount` command to process your local master file:

```
# /usr/sbin/autofs mount -m -f local_master_file
```
6. Use the `rcmgr` utility to configure AutoFS to start each time you boot your system. Note that the AutoFS parameters in the following steps are case sensitive and must be typed in uppercase as shown.
 - a. Enable the AutoFS daemon by entering the following command:

```
# rcmgr -c set AUTOFS 1
```
 - b. Specify options for the `autofs d` daemon and the `autofs mount` command, as follows:

```
# rcmgr -c set AUTOFS_ARGS "options"  
# rcmgr -c set AUTOFSMOUNT_ARGS "-m -f local_master_file"
```

See `autofs d(8)` and `autofs mount(8)` for lists of the available options.

When the `autofs mount` command is executed, it installs intercept points into the kernel based on the maps you created. When users access the associated file systems, the kernel communicates with the `autofs d` daemon to mount and unmount the file systems based on the map entries.

To use NIS-distributed AutoFS maps, do the following:

1. Set up your system as an NIS client. See Section 9.3.3 for information on setting up an NIS client.
2. Start the `autofs d` daemon by entering the following command:

```
# /usr/sbin/autofs &
```

3. Use the `rcmgr` utility to configure AutoFS to start each time you boot your system. Note that the AutoFS parameters in the following steps are case sensitive and must be typed in uppercase as shown.

- a. Enable the AutoFS daemon by entering the following command:

```
# rcmgr -c set AUTOFS 1
```

- b. Specify options for the `autofs` daemon and the `autofsmount` command, as follows:

```
# rcmgr -c set AUTOFS_ARGS "options"  
# rcmgr -c set AUTOFSMOUNT_ARGS ""
```

See `autofs(8)` for a list of its available options. Setting the `autofsmount` command to run with no options indicates that AutoFS is to use the NIS-distributed `auto.master` file.

The NIS master server serves all AutoFS maps in the domain. When the `autofsmount` command is executed, it uses the master `auto.master` file to determine the location of other maps, their local mount points, and the mount options.

If you alter your local or NIS-distributed maps at any time, you must process the map with the `autofsmount` command to apply the changes. Note that you cannot update map entries while an active NFS file system is mounted on the designated mount point. You must unmount the NFS file system before the AutoFS mount-update takes effect.

See `autofs(8)` and `autofsmount(8)` for more information. See `sys_attrs_autofs(5)` for tuning information.

10.6.2.3 Specifying automount and autofsmount Arguments

You can specify arguments for the `automount` or `autofs` daemons from the command line, in a local `auto.master` map, in an NIS-distributed `auto.master` map, or some combination of the three. However, it is important to know that the daemons read and carry out their instructions in the following order:

1. Command line information, such as additional mount points or replacements to entries in a master map, are read first. Command line information takes precedence over instructions in any maps — local or NIS-distributed.
2. Instructions in a local `auto.master` map (specified with the `-f` option) are read next. The information in the local master map overrides information in an NIS-distributed master map.
3. Information in the NIS-distributed master map is read last.

When you invoke the `automount` or `autofs` commands without any options, they look for a distributed NIS map called `auto.master`. If they find one, the commands check the master map for information about the location of other maps, their local mount points, and the mount options. If they do not find one, and if no local `auto.master` is specified, the commands exit.

You can pass command arguments to the `automount` daemon from the NFS Client dialog box of the SysMan Menu as documented in Section 10.3.2. You can also pass arguments to either `automount` or `autofs` in one of the following ways:

- Specify all of the arguments to either command on the command line. For example:

```
# automount /net -hosts \  
/home /etc/auto.home -rw,intr \  
/- /etc/auto.direct -ro,intr
```

- Specify all of the arguments to either command in the `rc.config.common` file by using the `rcmgr` utility. Arguments you specify in this file are passed to the command when you boot your system. For example:

```
# rcmgr -c set AUTOMOUNT_ARGS "/net -hosts \  
/home /etc/auto.home -rw,intr \  
/- /etc/auto.direct -ro,intr"
```

For the `autofs` command, the parameter to set is `AUTOFSMOUNT_ARGS`, as follows:

```
# rcmgr -c set AUTOFSMOUNT_ARGS "/net -hosts \  
/home /etc/auto.home -rw,intr \  
/- /etc/auto.direct -ro,intr"
```

- Include the arguments from the previous examples in an NIS-distributed `auto.master` map:

```
/net    -hosts  
/home  /etc/auto.home      -rw,intr  
/-     /etc/auto.direct    -ro,intr
```

If this NIS `auto.master` map is distributed, typing the `automount` command or the `autofs` command at the superuser prompt (`#`) produces the same results as the previous command line.

- Include the arguments in a local `auto.master` file and use the `-f` option to instruct the `automount` command or the `autofs` command to process the local `auto.master` file. The `-f` option instructs these commands to consult the local master map first and then the NIS-distributed master map. For example:

```
# automount -f /etc/auto.master
```

You can also add the `-m` option, which forces the commands to ignore the NIS-distributed master map completely, if there is one. For example:

```
# automount -m -f /etc/auto.master
```

- Specify mount points on the command line, in addition to those included in the local `auto.master` file. For example:

```
# automount -f /etc/auto.master \  
/src /etc/auto.src -ro,soft
```

- Nullify one of the entries in the local `auto.master` map. For example:

```
# automount -f /etc/auto.master /home -null
```

This option is currently not supported by the `autofs` command.

- Replace an entry in the local `auto.master` map with one of your own. For example:

```
# automount -f /etc/auto.master \  
/home /mine/auto.home -rw,intr
```

See `automount(8)` and `autofs(8)` for more information on these commands and their arguments.

10.6.3 Unmounting a Remote File System or Directory

Unmounting a remote file system or directory removes access to a particular file system or directory that is being imported from an NFS server; you can still import other directories or file systems. If you do not want to import any file systems, you might want to deconfigure your NFS client as documented in Section 10.4.

To unmount a remote file system or directory by using the SysMan Menu, do the following:

1. From the SysMan Menu, select **Networking**→**Additional Network Services**→**Network File System (NFS)**→**Configure system as an NFS client** to display the **Configure NFS Client** dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman nfs_client
```

2. Select the **Mount Network Directories** button to display the **Mount Network Directory** dialog box.

A list of NFS-mounted directories that are saved in the `/etc/fstab` file is displayed. Remote file systems that you mounted by using the `mount` command are not included in this list. Use the `umount` command to unmount these file systems. See `umount(8)`.

3. Select the entry that you want to unmount from the list.
4. Select Delete to remove the highlighted entry from the list. Repeat steps 3 and 4 to remove additional entries
5. Select OK to save the current list of imported directories in the `/etc/fstab` file.
You are informed that the changes have been made. Select OK to dismiss the message and to close the Mount Network Directory dialog box.
6. Select OK to close the NFS Client dialog box.

You can also add and modify your imported directories with the Mount Network Directory dialog box. See Section 10.6.1 and the online help for more information.

Optionally, you can use the `mount` or `umount` commands to mount or unmount remote file systems from the command line. Or, you can use a text editor to directly add, modify, or delete entries in the `/etc/fstab` file. See `mount(8)`, `umount(8)`, and `fstab(4)` for more information.

UNIX-to-UNIX Copy Program

The UNIX-to-UNIX Copy Program (UUCP) is a group of programs that enables batched, error-free file transfer and remote command execution between two UNIX systems. UUCP is typically used to transfer electronic mail, network nets, and public domain software over low-speed, low-cost communications links. Tru64 UNIX implements the HoneyDanBer version of UUCP.

This chapter describes:

- The UUCP Environment
- How to configure your system for UUCP
- How to manage UUCP

For general information about UUCP see `uucp_intro(7)`. For information on how to use UUCP, see the *Command and Shell User's Guide*.

For troubleshooting information, see Section 15.13.

11.1 UUCP Environment

In the UUCP environment, systems can be connected to each other in the following ways:

- Directly connected to each other, if they are in close proximity
- Connected through modems and a telephone network, if they are not in close proximity
- Connected through a local area network (LAN), if they are not in close proximity

Figure 11–1 shows two simple UUCP configurations. Figure 11–2 shows a sample UUCP configuration on a LAN in which Host A has a TCP/IP connection with Host C.

Figure 11–1: Sample Simple UUCP Configuration

ZK-1174U-AI

Figure 11–2: Sample UUCP Over TCP/IP Configuration

ZK-1175U-AI

11.2 Planning UUCP

This section describes those tasks you need to do before configuring UUCP.

11.2.1 Verifying the Correct Hardware

In verifying the correct hardware, you need to verify both the cables and modems, if used.

Make sure you are using the correct cable to connect to the serial port of your system. If you do not, you might experience signal degradation and the software will fail to function properly.

If the two systems are in close proximity to each other, use one of the null modem cables listed in Table 6-1.

If the two systems are connected through modems and telephone lines, see Table 6-7 for a list of modem cables to use. When using modems with UUCP, make sure that both the local and the remote modems are correctly configured.

UUCP can also be configured to run over TCP/IP local area networks (LANs). For information on running UUCP over a LAN, see `uucp_manual_setup(7)`.

11.2.2 Preparing for the Configuration

UUCP configuration consists of defining the following parts:

- Connection information for your system
- Dial-up information for outgoing calls
- Information for receiving incoming calls

The type of information you need depends on the types of connections you plan to set up and use. The following sections contain worksheets that you can use to record the information required to configure UUCP.

11.2.2.1 Information for Connections

Figure 11-3 shows the UUCP Setup Worksheet. If you are viewing this manual online, you can use the print feature to print a copy of the worksheet. The sections that follow explain the information you need to record on the worksheet.

Figure 11–3: UUCP Setup Worksheet

UUCP Setup Worksheet

Type of connection: Modem Direct link TCP/IP

Modems:

 Modem type: _____

 Baud rate: _____ Any

 Device name: _____

 /etc/inittab entry ID: _____

Direct links:

Remote system name: _____ Direct

 Baud rate: _____ Any

 Device name: _____

 /etc/inittab entry ID: _____

TCP/IP:

Outgoing connections: Yes No

Incoming connections: Yes No

Type of connection

The types of connections you want to configure. You can configure one or all of the following connections:

- **Modems** — Modems enable you to use UUCP over analog transmission facilities, which include telephone lines.
- **Direct (hardwired) links** — Direct hardwired links connect systems with cables.
- **TCP/IP** — Connections using the TCP/IP protocol.

For modem connections, supply the following information:

Modem type

The type of modem you want to use. The supported devices are listed in the `/usr/lib/uucp/Devices` file. For more information, see `uucp_manual_setup(7)`.

Baud rate or Any

The speed at which the modem is to operate; for example: 1200, 2400, 9600, or any.

Device name

The name of the tty device that you want the modem to use, as listed in the `/dev` directory. If you are unsure of the terminal device, see `ports(7)`.

/etc/inittab entry ID

The process ID for the `ugetty` process entry in the `/etc/inittab` file. The `ugetty` process sets up speed, terminal flags, and the line discipline for managing terminals. For more information, see `ugetty(8)`.

Note

Run the `ugetty` command only on RS-232 lines, not printer or console lines.

For direct link connections, supply the following information:

Remote system name or Direct

The type of direct link. If you want to connect to a specific remote system, enter the name of the remote system. This restricts connections to that system only.

If you want to connect to any system to which you have a direct hardwired connection, check `Direct`.

Baud rate or Any

The speed at which the direct link is to operate; for example: 1200, 2400, 9600, or any.

Device name

The name of the tty device that you want the direct link to use, as listed in the `/dev` directory. If you are unsure of the terminal device, see `ports(7)`.

/etc/inittab entry ID

The process ID for the `ugetty` process entry in the `/etc/inittab` file. The `ugetty` process sets up speed, terminal flags, and the line discipline for managing terminals. For more information, see `ugetty(8)`.

Note

Use the `uucp` command to configure only RS-232 lines, not printer or console lines.

For TCP/IP connections, supply the following information:

Outgoing connections

If you want to configure UUCP to place outgoing calls over TCP/IP, check Yes. When you enable UUCP to place outgoing calls over TCP/IP, an entry for TCP/IP is added to the `/usr/lib/uucp/Devices` file.

Otherwise, check No.

Incoming connections

If you want to configure UUCP to accept incoming calls over TCP/IP, check Yes. When you enable UUCP to accept incoming calls over TCP/IP, the `/etc/inetd.conf` file is modified. In addition, you must stop and restart the `inetd` daemon to be able to accept UUCP calls over TCP/IP.

Otherwise, check No.

11.2.2.2 Information for Outgoing Systems

Figure 11-4 shows the UUCP Outgoing Systems Worksheet. If you are viewing this manual online, you can use the print feature to print a copy of the worksheet. The sections that follow explain the information you need to record on the worksheet.

Figure 11–4: UUCP Outgoing Systems Worksheet

UUCP Outgoing Systems Worksheet	
Remote system name:	_____
Type of connection:	<input type="checkbox"/> Modem <input type="checkbox"/> Direct link <input type="checkbox"/> TCP/IP
TCP/IP conversation protocol:	<input type="checkbox"/> g <input type="checkbox"/> t <input type="checkbox"/> e <input type="checkbox"/> f
Calling times:	_____
Baud rate:	_____ <input type="checkbox"/> Any
Phone number (for modem):	_____
Login ID:	_____
For modem/direct links, expect-send string:	<input type="checkbox"/> Carriage returns <input type="checkbox"/> None <input type="checkbox"/> Prompt

Remote system name

The name of the remote system to which you plan to connect.

Type of connection

The type of the connection. Check modem, direct hardwired, or TCP/IP. You must configure the type of the connection with the information from Section 11.2.2.1.

TCP/IP conversation protocol

For TCP/IP connections, the TCP/IP conversation protocol, which can be one of the following:

- g — Specifies the default protocol, which provides error checking.
- t — Presumes an error-free channel and therefore is not reliable for use with modem connections.
- e — Used to communicate with sites that are running both Tru64 UNIX and other UNIX versions of UUCP.
- f — Relies on flow control of the data stream. It is meant for working over links that can virtually be guaranteed to be error free, specifically X.25/PAD links.

Calling times

The times when your system is allowed to connect to the remote host. You can select the following times:

- Any time of any day

- Evenings — Monday to Friday 5 p.m. to 8 a.m.; Saturday and Sunday, all day
- Any three nights — You can choose the three nights from the following:
 - Monday to Friday, 11 p.m. to 8 a.m.
 - Saturday, all day
 - Sunday, until 5 p.m.
- Never

Baud rate or Any

The baud rate that corresponds to a device you configured in the `/usr/lib/uucp/Devices` file, or you can specify any, if the device can be used at any speed.

Phone number (for modem)

For modem connections, the telephone number of the remote system. You can enter the complete telephone number or a dialing prefix and the telephone number.

A dialing prefix is defined in the `/usr/lib/uucp/Dialcodes` file. The `/usr/lib/uucp/Dialcodes` file contains dial code abbreviations and partial phone numbers that complete the telephone entries in the `/usr/lib/uucp/Systems` file. Entries in the `/usr/lib/uucp/Dialcodes` file contain an alphabetic prefix attached to a partial phone number that can include, for example, access codes, area codes, and exchange numbers.

If you know the dialing prefix, enter it on the worksheet. If none is defined, enter it and the sequence of numbers to be associated with the prefix.

Login ID

The login name for your system on the remote system. This must match the information in the `/etc/passwd` file on the remote system. Ask the administrator of the remote system for the login name and password that is assigned to your system on the remote system. The administrator of the remote system must include the login name and password for your system in the remote system's `/etc/passwd` file.

Note

Although the password for the login ID on the remote system is required in order to configure UUCP, to protect system security do not write the password on this worksheet.

For modem/direct links, expect-send string

The *expect-send* string to be used immediately before performing the login on the remote system. You can choose one of the following:

- To send a series of carriage returns before expecting any characters from the remote system
- To specify no *expect-send* strings
- To be prompted to enter *expect-send* strings

Modems usually use a series of carriage returns as an *expect-send* string.

For more information on *expect-send* strings, see *Systems(4)*.

11.2.2.3 Information for Incoming Systems

Figure 11–5 shows the UUCP Incoming Systems Worksheet. If you are viewing this manual online, you can use the print feature to print a copy of the worksheet. The sections that follow explain the information you need to record on the worksheet.

Figure 11–5: UUCP Incoming Systems Worksheet

UUCP Incoming Systems Worksheet	
Remote system name:	_____
Local system name:	_____
Login ID:	_____
Alternative login ID:	_____
REQUEST option:	<input type="checkbox"/> Yes <input type="checkbox"/> No
SENDFILES option:	<input type="checkbox"/> Yes <input type="checkbox"/> Call
Additional READ/WRITE locations:	_____
Additional NOREAD/NOWRITE locations:	_____
Commands:	_____ _____ _____
VALIDATE option:	<input type="checkbox"/> Yes <input type="checkbox"/> No
CALLBACK option:	<input type="checkbox"/> Yes <input type="checkbox"/> No
Phone number (for modem):	_____

Remote system name

The name of the remote system you want to allow to establish incoming UUCP connections.

Local system name

The name of your system. The default provided is the name that you assigned to your system at installation.

Login ID

The login ID for the remote system. The login ID is automatically added to the `/etc/passwd` file on your system.

By convention, the login ID that you assign to a remote system establishing incoming connections is the system name prefixed with an uppercase u (U). For example, if you specify `machine1` for incoming connections, the login ID, by convention, is `Umachine1`; however, you can select any login ID.

You also have the option of adding a comment to the `/etc/passwd` file for this login ID.

Alternative login ID

You have the option to assign more than one login ID for each incoming system. Assigning multiple logins to a remote system allows you to maintain better access control for users on the remote system. With multiple logins, you can grant privileged users on the remote system more access on your system than you do to nonprivileged users. With multiple logins, you can assign multiple sets of permissions.

You must provide this information to the administrator of each remote system that will connect to your system as an incoming system.

REQUEST option

If you want a remote system to ask for any queued work on the local system that is meant for that remote system, check Yes; otherwise, check No.

If you check Yes, remote system users can transfer files to and execute commands on a local system more easily. If security is a consideration, you can restrict this access so that the local system retains control of file transfers and command executions initiated by remote systems.

SENDFILES option

If you want the local system to try to send queued work to the calling remote system after the remote computer finishes transferring files to or executing commands on the local system, check Yes.

Security considerations at your site might require that you limit a remote system's access to the local system. In this case, check Call to send queued work to the remote system only when the local system contacts the remote system.

Additional READ/WRITE locations

If you do not specify pathnames in the READ and WRITE options, uucp permits files to be transferred only to the `/usr/spool/uucppublic` directory. However, if you specify pathnames in these options, you must enter the pathname for every source and destination. If you enter a pathname in either option, you must also explicitly specify the public directory if you want the `uucico` daemon to be allowed to place files in that location.

Additional NOREAD/NOWRITE locations

These options allow you to explicitly specify directories and files on the local system to which the remote system cannot transfer data. These are exceptions to the READ and WRITE options.

Commands

A list of commands the remote system is allowed to run on the local system. If you list a set of commands, that list comprises the new default command set for the systems listed in the MACHINE entry of the `/usr/lib/uucp/Permissions` file. The default is the command `rmail only`.

VALIDATE option

If you want the calling remote system to use a specific ID and password, check Yes; otherwise, check No.

If you use this option, no other ID from the remote system can call in. Several systems, however, can use the same ID. The VALIDATE option is meaningful only when the login ID and password are protected.

CALLBACK option

If you want the local system to contact the remote system before the remote system can transfer any files to the local system, check Yes; otherwise, check No.

If both systems use the `CALLBACK` option in their respective `Permissions` files, they will never be able to communicate with each other.

Phone number (for modem)

For modem connections, the phone number and speed of the modem attached to the local system. You must provide this information to the administrator of each remote system that will connect to your system as an incoming system.

11.3 Configuring UUCP

After you complete the required UUCP planning, use the `uucpsetup` script to configure UUCP. To invoke the `uucpsetup` script, enter the following command:

```
# /usr/sbin/uucpsetup
```

By default, the `uucpsetup` script prompts you for the information required to configure connections, incoming systems, and outgoing systems. To configure only specific components, you can specify one of the other options listed in Table 11-1:

Table 11-1: Options for `uucpsetup` Command

Use this command:	If you want to:
<code>uucpsetup</code>	Configure connections, incoming systems, and outgoing systems
<code>uucpsetup -i</code>	Configure the incoming systems only
<code>uucpsetup -o</code>	Configure the outgoing systems only
<code>uucpsetup -p</code>	Configure the <code>Poll</code> file

The following sections provide information on how to configure connections, incoming systems, outgoing systems, and the `Poll` file.

11.3.1 Configuring Connections

After you invoke `uucpsetup`, use the the information you gathered in Section 11.2.2.1 to configure UUCP connections. The following guidelines explain how to answer some of the script questions:

- Device names — The script lists the available device names. Enter the last letter or number of the device that you want the modem to use. For example, if you want to use `tty01`, enter 1.

- `/etc/inittab` entry ID — The script prompts you for the *Identifier* field and asks if this entry will be used in shared mode. It automatically supplies information for the other fields. No two processes can have the same ID.

The following example illustrates how to select the process ID (PID) u4:

```
Select an ID for the process in /etc/inittab file
For example type 'u1': u4
```

The ID that you select is checked against those that exist in the `/etc/inittab` file. If the ID that you assign exists, the `uucpsetup` script prompts you to enter another ID.

You must also indicate whether the system will use the modem or direct line in shared mode.

For more information on the `/etc/inittab` file, see `inittab(4)`.

11.3.2 Configuring Outgoing Systems

After you invoke the `uucpsetup` script, use the the information you gathered in Section 11.2.2.2 to configure UUCP for outgoing systems. This enables you to use UUCP to connect to other remote systems.

If you are doing a complete UUCP setup, the `uucpsetup` script prompts you for information on outgoing systems when you finish configuring connections. The following guidelines explain how to answer some of the script questions:

- Phone number — If you choose a dialing prefix and the telephone number, the script prompts you to enter a prefix to be defined in the `/usr/lib/uucp/Dialcodes` file. After you enter the prefix, the script prompts you for the meaning of the prefix. Enter the sequence of numbers that you want the system to substitute for the prefix. The following example illustrates how to define the prefix `btown` to be the dialing sequence 1617772:

```
Enter the prefix for the Dialcodes file; for example "boston"
stands for 9=16171234 : btown
What telephone number does the prefix stand for; Please include
the long distance access code, area, or country codes;
for example type 9=1617123 : 9=1617772
```

The 9 in this example is used to obtain a secondary dial tone. The 9 is site specific; it can be different for your site. The equal sign (=) is used with the 9, or number for your site, and means “wait for the dial tone.” Following the equal sign (=) is the rest of the number. Enter the rest of the number.

- Password — For security considerations, the password is not written on the worksheet. However, when the script prompts for it, you must enter it.

If you define an outgoing TCP system, edit the `/etc/uucp/Systems` file and add an entry for the remote system. The remote system name must be the fully qualified name.

When you finish configuring your outgoing system, you need to configure the `/usr/lib/uucp/Poll` file. See Section 11.3.4 for more information.

11.3.3 Configuring Incoming Systems

After you invoke the `uucpsetup` script, use the the information you gathered in Section 11.2.2.3 to configure UUCP for incoming systems. This enables specific remote systems to connect to your system using UUCP.

If you are doing a complete UUCP setup, the script prompts you for information on incoming systems when you are done configuring outgoing systems.

The first time you add an incoming system, the Incoming Systems Configuration menu prompts you for the name of the system you want to add. After you add an incoming system, this menu offers you the following choices:

- Specify a remote system name.
- Specify options for all the other systems not specified in the `Permissions` file but listed in the `Systems` file.
- Neither. If you choose this option, the script terminates and the defaults for the options are not entered in the `Permissions` file.

The following guidelines explain how to answer some of the script questions:

- **Password** — The `uucpsetup` script invokes the `vipw` command, which starts your default editor (defined in the `EDITOR` environment variable) and allows you to edit the UUCP entry for the incoming system. After you are finished editing the `/etc/passwd` file, save the file, exit the editor, and supply a password for the new entry. The following example shows output from this process on a system that is configured to use the `vi` utility as its default editor:

```
Invoking 'vipw'.
Press RETURN to continue...
Return
root:fQPPWjF20Dfso:0:1:Charles Root:/:bin/csh
nobody:*Nologin:4294967294:4294967294:anonymous NFS user:/:
daemon:*:1:1:Mr Background,,,:/
uucp:No Login:2:2:UNIX-to-UNIX Copy:/usr/spool/uucppublic:\
/usr/lib/uucp/uucico
bin:*:3:4:Mr Binary:/bin:
marcy:5jW0VXKeP6n1E:1242:15:Marcy Darcy,,,:\  
/usr/users/marcy:/bin/false
Umachine1:H/kj951Fq12ub:2:2:uucp login:/usr/spool/uucppublic:\
```

```

    /usr/lib/uucp/uucico
~
~
~
"/etc/ptmp" 15 lines, 933 characters
:wq
15 password entries, maximum length 100

You must enter a password
Changing password for Umachine1.
New password:
Retype new password:

```

You must provide this information to the administrator of each remote system that will connect to your system as an incoming system.

- **Commands** — The script prompts you for each command separately.

If you define an incoming UUCP system and your system uses NIS, edit the `/etc/passwd` file and add the wildcard (+:) as the last line (if not there already).

11.3.4 Configuring the Poll File

After you finish configuring an outgoing system, you need to configure the `/usr/lib/uucp/Poll` file to schedule the intervals at which the local system will poll remote systems. You can configure the `Poll` file by invoking the `uucpsetup` script with the `-p` option and completing the following steps:

1. Enter 1 (Configure the Poll file) from the Poll File Configuration Menu.
2. Enter the name of the remote system, which has been configured in the `/usr/lib/uucp/Systems` file as an outgoing system.
3. Enter the sequence of hourly intervals. For example, to have the system polled every 4 hours, enter 0 4 8 12 16 20.
Press Return to update the `Poll` file.
4. To add another system to the `Poll` file, enter y; otherwise, press Return to exit `uucpsetup`.

See `Poll(4)` for more information about the `Poll` file.

11.3.5 Configuring the uucico Daemon

The `uucico` daemon transfers UUCP command, data, and execute files to remote systems. Both the local and remote systems run the `uucico` daemon, and the two daemons communicate with each other to complete transfer requests.

Typically, the `uucico` daemon is set up as the UUCP user's login shell for incoming connections, or it is automatically called by various UUCP commands for outgoing connections, and no further configuration is necessary. However, you might need to specify the type of flow control `uucico` uses for certain UUCP transfers. For example, if you establish a connection to a terminal server via a modem and then `telnet` to a UUCP account, you might require a different type of flow control than a user who initiates UUCP transfers via a serial port connection.

To specify the type of flow control that the `uucico` daemon uses, set the `FLWCTL` environment variable for the accounts on your system that use UUCP connections. Permitted values for `FLWCTL` are: `HW` (hardware), `SW` (software), `HSW` (hardware and software), and `NONE`. The local and remote systems must use the same type of flow control. If the remote site runs UUCP on a different platform, set `FLWCTL` to `NONE` on the Tru64 UNIX system.

For example, to establish a UUCP connection over `telnet`, you would set flow control to `NONE` as follows:

```
$ export FLWCTL=NONE
$ /usr/lib/uucp/utry remote_site
```

On a system that is configured to allow other sites to dial in, you can use the following procedure to create a customized script that automatically sets the `FLWCTL` variable:

1. Create a file, optionally called `uu_start`, that contains the following commands:

```
#!/bin/ksh
export FLWCTL=NONE
exec /usr/lib/uucp/uucico $*
```

2. Change the permissions on the file to make it executable:

```
# chmod +x /usr/local/bin/uu_start
```

3. Change the UUCP account's login shell from `/usr/lib/uucp/uucico` to the new executable file:

```
# chsh uucp
Old shell: /usr/lib/uucp/uucico
New shell: /usr/local/bin/uu_start
```

11.4 Monitoring the File Transfer Queue

Monitoring the file transfer queue enables you to determine the status of several types of networking operations, including jobs that have been queued

on a local system for transfer to a remote system. General users and system administrators can monitor the file transfer queue.

11.4.1 Getting Queue Status Manually

To get queue status manually, use the `uustat -q` command.

This command lists the jobs queued for all systems. The jobs listed in the queue include jobs that are currently executing as well as jobs that are waiting to execute. If a status file exists for a system, its date, time, and status information are reported.

The `uustat` command also allows you to do the following:

- Get information about the status of mail activities
- Control `uucp` jobs queued to run on remote systems
- Check the status of `uucp` connections to other systems, using the `-m` flag
- Cancel transfer requests, using the `-k` flag
- Monitor requests for file transfers generated with the `uucp` and `uuto` commands, and requests for command executions generated with the `uux` command

See `uustat(1)` for more information on `uustat` flags.

The following example shows all jobs in the current queue: one command file for system `host4`, three command files for system `host6`, and two command files for system `host8`. The command files for system `host6` have been in the queue for 2 days.

```
# uustat -q
host4 1C Sat May 9 11:12:30 1992 SUCCESSFUL
host6 3C(2) Sat May 9 11:02:35 1992 CAN'T ACCESS DEVICE
host8 2C Sat May 9 10:54:02 1992 NO DEVICES AVAILABLE
```

11.4.2 Getting Queue Status Automatically

You can automatically receive status information about the `uucp` file transfer queue. To enable this mechanism, edit the `/usr/spool/cron/crontabs/uucp` file and delete the comment character (`#`) from the beginning of the following line:

```
# 48 8,12,16 * * * /usr/lib/uucp/uudemon.admin > /dev/null
```

In the preceding example:

48	Represents minutes
8,12,16	Represents hours based on 24-hour clock notation
* * *	Three asterisks are placeholders representing the day of the month, the month of the year, and the day of the week

The `cron` daemon will run the `uudemon.admin` shell script daily at 48 minutes past the hours 8, 12, and 16; that is, at 8:48 a.m., 12:48 p.m., and 4:48 p.m. The `uudemon.admin` script sends mail to the `uucp` login ID containing queue status information.

Note

These times are the defaults. You can change the time to fit the needs of your site by editing the line in the `/usr/spool/cron/crontabs/uucp` file.

You can also manually run the `uudemon.admin` script by entering the following command:

```
# /usr/lib/uucp/uudemon.admin
```

11.4.3 Guidelines for Checking Queue Status

When examining queue status, check the number and age of the file-transfer and command execution requests queued in the `/usr/spool/uucp/system_name` directory. In some cases, queued jobs remain in the queue for some time, essentially going undelivered. The status information you need to check includes:

- The age in days of the oldest request in each queue
- The number of times the local system has tried and failed to reach the specified computer
- The reason for the failure to contact the specified system

See Appendix E for error messages and solutions.

If necessary, delete the files in the queue, either manually or automatically. See Section 11.5 for information on deleting files.

11.5 Cleaning Up the Spooling Directories

Each system connected by UUCP has the following spooling directories:

- The `/usr/spool/uucp/system_name` directory is the UUCP spooling directory. It contains queued local requests for file transfers and

command executions on remote systems. These files are removed by the `uucp` program after they are transferred to the designated system.

- The `/usr/spool/uucppublic` directory is the UUCP public directory. When a user transfers a file to a remote system or issues a request to execute a command on an other system, the files generated by these UUCP commands are stored in the public directory on the designated system.

Depending upon the size of your installation and the number of files sent to the local `/usr/spool/uucppublic` directory by users on remote systems, the public directory can become quite large. Similarly, if requests are not transferred to remote systems for whatever reasons, the spooling directory could also become quite large. Therefore, part of UUCP management is to clean up the spooling directories and conserve disk resources.

11.5.1 Cleaning Up Directories Manually

To clean up the spooling directories manually, log in as root and remove the files by using the `uucleanup` command.

The `uucleanup` program performs the following tasks:

- Informs the system manager of requests to send files to and receive files from remote systems that the local system cannot contact.
- Warns users about requests that have been waiting in the spooling directory for a given period of time. The default is 1 day.
- Returns to the original sender mail that cannot be delivered.
- Removes all other files older than a specified number of days from the spooling directory.

Note

Depending on the size of your installation and the available storage space on the local system, you can set the age limit for any length of time. However, it is best to allow files to remain in the spooling directory for at least the default number of days.

See `uucleanup(8)` for more information on the `uucleanup` command options.

The following example deletes all old files in the UUCP spooling and public directories for system `host2` on the local system:

```
# uucleanup -shost2
```

11.5.2 Cleaning Up Directories Automatically

Although automatic cleanup is not enabled when UUCP is installed, you can enable it by doing the following:

1. Log in as root.
2. Edit the `/usr/spool/cron/crontabs/uucp` file and delete the comment character (`#`) from the beginning of the following line:

```
# 45 23 * * * ulimit 5000; /usr/lib/uucp/uudemon.cleanu > /dev/null
```

In the preceding example:

45	Represents minutes
23	Represents hours based on 24-hour clock notation
* * *	Three asterisks are placeholders representing the day of the month, the month of the year, and the day of the week

The cron daemon will start the `uudemon.cleanu` shell script daily at 45 minutes after hour 23; that is, at 11:45 p.m. The shell script in turn starts the `uucleanup` program. This time is the default. You can change the time to fit the needs of your site by editing the line in the `/usr/spool/cron/crontabs/uucp` file.

You can instruct the cron daemon to run the `uudemon.cleanu` shell script daily, weekly, or at longer intervals, depending on the number of `uucico` and `uuxqt` transactions that occur on the local system.

The `uudemon.cleanu` script incorporates the actions of the `uucleanup` program and performs the following additional tasks:

- Locates and deletes empty directories and files older than 30 days from the `/usr/spool/uucppublic` directory. This helps keep the local file system from overflowing when users send files to the public directory. If the local system does not have enough storage space to accommodate a large `/usr/spool/uucppublic` directory, you can change the 30-day default to a shorter time period by modifying the `uudemon.cleanu` shell script.
- Cleans up all the `uucp` spooling directories, including the public directories, unless you direct it to clean up only the directories of a specific system by issuing the `uucleanup -s system_name` command.
- Updates archived log files, removing log information more than 2 days old. The script removes log files for individual computers from the `/usr/spool/uucp/.Log` directory, merges them, and places them in the `/usr/spool/uucp/.Old` directory, which contains old log information.

- Mails a summary of the status information gathered during the current day to the UUCP login ID. You can modify the script to send status information to other login IDs, such as root.

The operating system allots UUCP a specified amount of storage space for any one log file; the number of blocks is determined by the default `ulimit` value. If the `uudemon.cleanu` script fails to execute because the `ulimit` value is set too low for the requirements of the local system, increase the default `ulimit` value.

See `uudemon(8)` for more information on command options.

11.5.3 Guidelines for Removing Files

When removing files from the queue, observe the guidelines for the following files:

- **Execute files** — Usually, you can remove execute files that have been in the queue for at least 2 days, using either the `uucleanup` or `uudemon.cleanu` script. The execute files are still queued because the data files required to execute the specified command on the designated system were not transferred. Since data files are generally sent at the same time as execute files, the transfer probably failed at the point of destination. Execute files are named `X.filename` and data files are named `D.filename`.
- **Command files** — Before removing old command files, make every possible effort to establish the connection and transfer the files. You can then remove these files by using either the `uucleanup` or `uudemon.cleanu` script. Command files are named `C.filename`.

11.6 Viewing Log Files

The `uucp` program creates a log file for each remote system with which your local system communicates. Each time you use the networking utilities facility, `uucp` places status information about each transaction in the appropriate log file. Log file names can be in either of the following forms:

```
/usr/spool/uucp/.Log/daemon_name/system_name
```

```
/usr/spool/uucp/.Log/command_name/system_name
```

In the preceding example:

`daemon_name` Represents either `uucico` (called by the `uucp` and `uuto` commands) or `uuxqt` (called by the `uux` command)

<i>command_name</i>	Represents either <code>uucp</code> or <code>uux</code>
<i>system_name</i>	Represents the name of the system with which your local system is communicating

To display individual log files, use the `uulog` command.

You can use the `uulog` command to display a summary of `uucp` and `uux` requests by user or by system. See `uulog(1)` for more information on the `uulog` command and its options.

Instead of viewing the log files individually, you can have the `uudemon.cleanu` script automatically append these log files to one primary log file, and then view only the primary log file.

The `uudemon.cleanu` script combines the `uucico`, `uuxqt`, `uux`, and `uucp` log files on a system and stores them in a directory named `/usr/spool/uucp/.Old`. By default, the `uudemon.cleanu` script saves log files that are up to two days old.

You can change the default by modifying the `-o2` option in the following line in the `uudemon.cleanu` script:

```
uucleanup -D7 -C7 -X2 -o2 -W1
```

If storage space is a problem on a particular system, consider reducing the number of days that the files are kept in the individual log files. See Section 11.5.2 for information on setting up the `uudemon.cleanu` script.

The following command displays the log file for `uucico` requests for system `host2`:

```
# uulog -s host2
```

The following command displays the log file for `uuxqt` requests for system `host1`:

```
# uulog -x host1
```

The following command displays the last 40 lines of the file transfer log for system `host6` and executes a `tail -f` command. Press `Ctrl/C` to terminate the command.

```
# uulog -f host6 -40
```

11.7 Cleaning Up `su`log and `cron/log` Files

The following two system log files are affected by the `uucp` program:

- The `/usr/adm/su`log file contains a history of superuser (`su`) command usage. The `uudemon` entries in the `/usr/spool/cron/crontabs/uucp` file each use the `su` command.

- The `/usr/adm/cron/log` file contains a history of all the processes generated by the `cron` daemon.

Both files can grow quite large over a period of time. Purge these files periodically to keep them at a reasonable size. See *System Administration* for information on these files.

11.8 Limiting the Number of Remote Executions

The `Maxuuxqts` file, located in the `/usr/lib/uucp` directory, limits the number of `uuxqt` processes running simultaneously on a local system. Typically, the file requires no configuration or maintenance unless the system on which it is installed is utilized frequently and heavily by users on remote systems.

To change the number of `uuxqt` processes on the system, edit the `Maxuuxqts` file and change the ASCII number to meet the needs of your installation; the default is 2. In general, the larger the number, the greater the potential load on the local system.

11.9 Scheduling Work in the Spooling Directory

When users issue `uucp` commands to copy files and execute remote commands, the files containing these work requests are queued for transfer in the local `/usr/spool/uucp/system_name` directory. The `uucp` daemon `uusched` schedules the transfer of these files.

11.9.1 Starting `uusched` Manually

You can start the `uusched` daemon manually to schedule jobs by executing the `uusched` command. See `uusched(8)` for a list of available options.

11.9.2 Starting `uusched` Automatically

Although you can start the `uusched` daemon manually, the preferred method is to start it automatically at specified intervals by using the `uudemon.hour` shell script, which is stored in the `/usr/lib/uucp` directory. The shell script, in turn, is started periodically by the `cron` daemon, based on instructions in the `/usr/spool/cron/crontabs/uucp` file.

The `/usr/lib/uucp/Maxuuscheds` file limits the number of remote systems that the `uucico` daemon can contact at any one time. This file is used in conjunction with the `uusched` daemon and the lock files in the `/usr/spool/locks` directory to determine the number of systems currently being polled.

The `Maxuuscheds` file requires no configuration or maintenance unless the system on which it is installed is utilized frequently and heavily by users on remote systems. You use this file to help manage system resources and load averages.

The `Maxuuscheds` file contains a number that you can change to meet the needs of your installation; the default is 2. In general, the larger the number, the greater the potential load on the local system.

See `uusched(8)` for more information on the `uusched` command and its options.

The following command starts the `uusched` daemon manually as a background process:

```
# /usr/lib/uucp/uusched &
```

11.10 Calling File Transfer Programs (`uudemon.hour`)

The `uudemon.hour` shell script is used in conjunction with the `Poll` file, the `uudemon.poll` shell script, and the `/usr/spool/cron/crontabs/uucp` file to initiate calls to remote systems. Specifically, `uudemon.hour` calls programs involved in transferring files between systems at specified hourly intervals.

You can instruct the `cron` daemon to run the `uudemon.hour` shell script at specified hourly intervals. The frequency at which you run the script depends on the amount of file transfer activity originating from the local computer.

Although the `uudemon.hour` shell script is not enabled when UUCP is installed, you can enable it by doing the following:

1. Log in as root.
2. Edit the `/usr/spool/cron/crontabs/uucp` file and delete the comment character (`#`) from the beginning of the following line:

```
# 25,55 * * * * /usr/lib/uucp/uudemon.hour > /dev/null
```

In the preceding example:

<code>25,55</code>	Represents minutes past the hour
<code>* * * *</code>	Four asterisks are placeholders representing the hour interval, the day of the month, the month of the year, and the day of the week

The `cron` daemon will run the `uudemon.hour` script at 25 minutes past the hour and again at 55 minutes past the hour; for example, at 8:25 a.m. and 8:55 a.m., 9:25 a.m. and 9:55 a.m., and so on.

These times are the defaults. You can change the time to fit the needs of your site by editing the line in the `/usr/spool/cron/crontabs/uucp` file.

If users on the local system initiate a large number of file transfers, you might need to specify that the `cron` daemon run the `uudemon.hour` script several times an hour. If the number of file transfers originating from the local system is low, you can probably specify a start time once every 4 hours, for example.

11.11 Polling Remote Systems (`uudemon.poll`)

The `uudemon.poll` shell script is used in conjunction with the `Poll` file, the `uudemon.hour` shell script, and the `/usr/spool/cron/crontabs/uucp` file to initiate calls to remote systems. The `uudemon.poll` shell script polls the systems listed in the `/usr/lib/uucp/Poll` file. In addition, it creates command files for the systems listed in the `Poll` file.

The time at which you run the `uudemon.poll` script depends on the time at which you run the `uudemon.hour` script. You generally schedule the polling shell script to run before the hourly script. This schedule enables the `uudemon.poll` script to create any required command files before the `cron` daemon runs the `uudemon.hour` script.

Although the `uudemon.poll` script is not enabled when UUCP is installed, you can enable it by doing the following:

1. Log in as root.
2. Edit the `/usr/spool/cron/crontabs/uucp` file and delete the comment character (`#`) from the beginning of the following line:

```
# 20,50 * * * * /usr/lib/uucp/uudemon.poll > /dev/null
```

In the preceding example:

<code>20,50</code>	Represents minutes past the hour
<code>* * * *</code>	Four asterisks are placeholders representing the hour interval, the day of the month, the month of the year, and the day of the week

The `cron` daemon will run the `uudemon.poll` script at 20 minutes past the hour and again at 50 minutes past the hour, for example, at 8:20 a.m. and 8:50 a.m., 9:20 a.m. and 9:50 a.m., and so on.

These times are the defaults. You can change the times at which the `cron` daemon executes the `uudemon.poll` script to correspond to the times you set up for the `uudemon.hour` script. Set the `cron` daemon to run the `uudemon.poll` script about 5 to 10 minutes before running the `uudemon.hour` script.

12

Network Time Protocol

The Network Time Protocol (NTP) provides accurate, dependable, and synchronized time for hosts on both wide area networks (WANs) like the Internet network and local area networks (LANs). In particular, NTP provides synchronization traceable to clocks of high absolute accuracy, and avoids synchronization to clocks keeping bad time. The Tru64 UNIX NTP subsystem is derived from the University of Delaware's implementation, NTP Version 4.98a.

This chapter describes:

- The Tru64 UNIX NTP subsystem and its components
- How to configure your system to use NTP
- How to enable the high-resolution clock
- How to manage NTP clients and servers

For introductory information on NTP, see the `ntp_intro(7)` reference page. For troubleshooting information, see Section 15.14. Also, for information about the latest releases of NTP, more examples of how to configure NTP subnets, and more extensive NTP troubleshooting information, visit the NTP website at <http://www.eecis.udel.edu/~ntp>.

As an alternative to NTP, you can set your system time by using the `rdate` command or the `timed` daemon.

Note

The `timed` daemon is provided only for compatibility; use NTP for time synchronization. If you plan to run both the `timed` daemon and NTP, configure NTP first and run the `timed` daemon with the `-E` option.

For more information on the `rdate` command, see `rdate(8)` and `ntp_manual_setup(7)`.

For more information on the `timed` daemon, see `timed(8)` and `timedsetup(8)`.

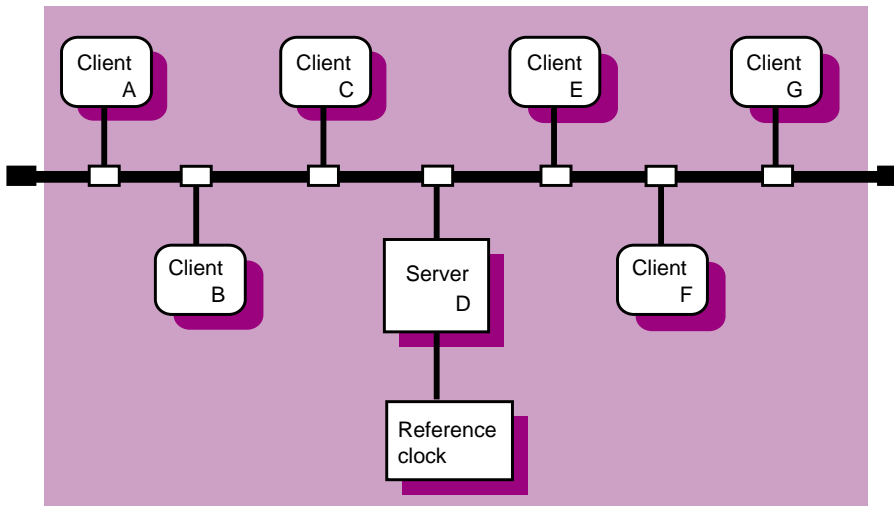

12.1 NTP Environment

In the NTP environment, systems can have the following roles:

- Client — An NTP client system is a system that synchronizes its time with local NTP servers.
- Server — An NTP server is a local system that synchronizes its time with an Internet NTP server or with a local reference clock, or both for better accuracy.

Figure 12–1 shows a sample NTP configuration on a LAN in which host D is an NTP server that uses a local reference clock as its time source. Hosts A, B, C, E, F, and G are NTP clients, synchronizing their time with host D.

Figure 12–1: Sample NTP Configuration (Local Clock)

ZK-1158U-AI

Figure 12–2 shows a sample NTP configuration in which host D is an NTP server that uses an Internet time server as its time source. Hosts A, B, C, E, F, and G are NTP clients, synchronizing their time with host D.

Figure 12–2: Sample NTP Configuration (Internet Source)

ZK-1159U-AI

12.2 Planning NTP

Your system can be a local NTP server or an NTP client, or both. Figure 12–3 shows the NTP Setup Worksheet, which you can use to record the information required to configure NTP. If you are viewing this manual online, you can use the print feature to print a copy of this worksheet. The following sections explain the information you need to record on the worksheet.

Figure 12–3: NTP Setup Worksheet

NTP Setup Worksheet				
Server				
Time source: _____				
Server Internet address:	Server name:	Version:	Stratum:	
_____	_____	_____	_____	
_____	_____	_____	_____	
_____	_____	_____	_____	
Client				
Local NTP server address:	Server name:	Version:		
_____	_____	_____		
_____	_____	_____		
_____	_____	_____		

12.2.1 Server Information

Time source

Your system's time source. For local NTP servers, the time source is one of the following:

- Internet NTP servers — If your system is connected to the Internet, you can obtain a list of possible NTP Internet servers from **<http://www.eecis.udel.edu/~ntp>** on the World Wide Web. Select a minimum of three systems from the server list with which to synchronize the time on your local NTP servers. Obtain permission from the contact person listed for each Internet server before specifying it as a server for your local NTP servers.
- A reference clock — If your network is not connected to the Internet network, you can select a system on your network to configure with a reference clock, which obtains its time via radio broadcasts or satellite transmissions. As a last resort, if no Internet servers or reference clock devices are available, you can select a system on your network to configure with a local reference clock, which means that the system uses its own CPU timekeeping unit as a reference clock.

See `ntp_manual_setup(7)` and `ntp.conf(4)` for information about configuring different types of reference clocks.

Server Internet address

The IP address of the Internet NTP server or the local reference clock. Local NTP servers are the time sources for NTP clients.

Server name

The host name of the Internet NTP server.

Version

The version of NTP daemon running on the Internet NTP server or the local reference clock. This can be Version 1 (the `ntpd` daemon), Version 2 (the `xntpd` daemon), or Version 3 (the `xntpd` daemon). Servers running Version 3.2 or earlier of the Tru64 UNIX operating system run Version 2 (the `xntpd` daemon); servers running Version 4.0 of the Tru64 UNIX operating system run Version 3 (the `xntpd` daemon).

Stratum

A stratum value describes the accuracy of a system's reference clock: the higher the number, the less accurate the clock.

If you are configuring a local reference clock, you can specify a higher stratum value to indicate that the clock's time is not very accurate. This discourages other systems from using your clock as a reliable time source, because NTP clients will obtain the time from the server with the lowest stratum they can find. For example, if you set a stratum of 8 for your local reference clock, NTP clients will ignore your server and use a server with stratum 2 or lower (if one can be found).

You can supply a value between 0–15 for the Stratum field; however it is best not to override the default value assigned by NTP unless you have a specific reason for doing so. For local reference clocks, that default value is 3. For other clocks, the default value is 0.

12.2.2 Client Information**Local NTP server address**

The local NTP server IP address. Local NTP servers are the time sources for NTP clients.

Server name

The local NTP server name.

Version

The version of NTP daemon running on the local NTP server. This can be Version 1 (the `ntpd` daemon), Version 2 (the `xntpd` daemon),

or Version 3 the (the `xntpd` daemon). Servers running Version 3.2 or earlier of the Tru64 UNIX operating system run Version 2 (the `xntpd` daemon); servers running Version 4.0 of the Tru64 UNIX operating system run Version 3 (the `xntpd` daemon).

12.3 Configuring NTP

Use the SysMan Menu application of the Common Desktop Environment (CDE) Application Manager to configure NTP servers and clients. To invoke the SysMan Menu application, follow the instructions in Section 1.1.1.

Note

Do not use the SysMan Menu to configure NTP on local NTP servers that use a local or external reference clock as a time source. Instead, see `ntp_manual_setup(7)` for instructions.

Also, if you plan to use both NTP and the `timed` daemon, set up NTP prior to setting up the `timed` daemon.

To configure NTP, do the following:

1. From the SysMan Menu, select Networking→Additional Network Services→Network Time Protocol (NTP)→Configure system as an NTP client to display the Configure NTP Client dialog box.

Alternatively, enter the following command on a command line:

```
# /usr/bin/sysman ntp_config
```

2. Indicate whether you want to enable authentication by selecting the appropriate check box. If you choose to enable authentication, you must enter at least one authentication key as follows; repeat the steps to add additional keys:
 - a. Select Add under the Authentication Keys list to display the Add/Modify dialog box.
 - b. Enter the Key Number and Key for a peer or peers. The Key Number is a number from 1–15 that identifies the Key. The Key is an alphanumeric password of 1–8 characters with no spaces.
 - c. Select OK to add the authentication key to the list and to dismiss the Add/Modify dialog box.

Your authentication keys are stored in the `/etc/ntp.keys` file when you save your configuration and close the Configure NTP Client dialog box.

3. Select Add under the Servers & Peers list to display the Add/Modify dialog box.
4. Enter the host name, mode, version, and key number for an NTP server. If the NTP Server's IP address is not available through DNS or NIS, you must add it to the `/etc/hosts` database on your system as described in Section 2.3.7.

For clients, enter the information for an NTP server that is local to your site.

For servers, enter the information for an Internet NTP server or a local reference clock. (See Section 12.2 for information.) If you are configuring a local reference clock, and you need to override the default stratum that the `xntpd` daemon assigns to it, select the Fudge Factor check box and select a value from 0 to 15 for the Stratum field.

The information will be recorded in the `/etc/ntp.conf` file. For clients, entries in this file are designated as server entries because clients can synchronize their time only with these systems. An NTP server, however, can contain server and peer entries in its `ntp.conf` file. A peer system can be synchronized to another system's time or it can synchronize another system's time to its own.

5. Select OK to validate the parameters you entered and to dismiss the Add/Modify dialog box. To add other NTP servers, repeat steps 3 through 5. It is best to specify at least three servers.
6. Indicate whether you want to correct large time differences by selecting the appropriate check box.

This option, enabled by default, allows `xntpd` to correct differences of more than 1000 seconds between your system time and your system's NTP server's time that occur after the `xntpd` daemon is started. The `ntpdate` command is run at boot time by the `/sbin/init.d/settime` script to correct initial time differences. If your system is sensitive to security threats, do not enable this option. If you do not use this option, time differences of more than 1000 seconds will cause the `xntpd` daemon to log a message to the `syslogd` daemon and exit.

7. Indicate whether you want to prevent time from being set backwards by selecting the appropriate check box. The default is to allow the `xntpd` daemon to set the system time backward.
8. Select OK to accept the configuration and to close the Configure NTP Client dialog box.
9. A new dialog box is displayed indicating that the changes have been saved and prompting you to start the `xntpd` daemon.

10. Select Yes to start the daemon and apply your changes immediately, or select No to close the Configure NTP Client dialog box and apply the changes the next time you reboot your system.

Note

When you start NTP, the system attempts to synchronize its clock with an NTP server's clock. If you previously enabled a screen saver on your system, the time difference might be enough to activate it. In some cases, this blanks the screen, but it does not harm the system. Move the mouse or hit a key on the keyboard to reactivate the display.

If you choose Yes, you are informed that the NTP daemons have been started. Select OK to dismiss the message and to close the Configure NTP Client dialog box.

You can modify your NTP configuration after the initial setup. You can also stop and restart the `xntpd` daemon as necessary. See the online help for more information.

12.4 Enabling the High-Resolution Clock

The operating system includes an optional high-resolution clock that can be used for time-stamping and for measuring events that occur on the order of microseconds, such as the time spent in a critical code path. Programmers might be able to use this information to find the source of a bug or to determine where a program can be optimized to improve performance.

To enable the high-resolution clock, add the following line to the kernel configuration file and rebuild the kernel:

```
options MICRO_TIME
```

The system clock (`CLOCK_REALTIME`) resolution as returned by the `clock_getres` function does not change, nor does the timer resolution. However, the time as returned by the `clock_gettime` routine is extrapolated between the clock ticks, and the granularity of the time returned is in microseconds. The resulting time values are SMP-safe, they are monotonically increasing, and they have an apparent resolution of 1 microsecond.

12.5 Monitoring Hosts Running the `xntpd` Daemon

You can monitor the hosts running the `xntpd` daemon by using either the `ntpq` command or the `xntpd` command.

To monitor the local host's NTP status using the `ntpq` command, use the following syntax:

```
ntpq [options...]
```

To monitor remote hosts' NTP status using the `ntpq` command, use the following syntax:

```
ntpq [options...] host1 host2...
```

Table 12–1 shows the `ntpq` command options.

Table 12–1: Options to the `ntpq` Command

Option	Function
<code>-c subcommand</code>	Interprets <i>subcommand</i> as an interactive format command and adds it to a list of commands to be executed on the specified host or hosts
<code>-i</code>	Forces <code>ntpq</code> to operate in interactive mode
<code>-p</code>	Prints a list of peers and a summary of their state

You can specify `ntpq` subcommands on the command line with the `-c` option, or you can run the `ntpq` program interactively with the `-i` option. When you are finished entering subcommands in interactive mode, enter `quit` to exit the program.

By default, the subcommands apply to the local host. You can specify a host other than the local host on the command line or with the `host` subcommand in interactive mode. See `ntpq(8)` for more information about this command and its subcommands.

The following example shows normal output from the `ntpq` command with the `-p` option (or `peers` subcommand):

```
% ntpq -p
      remote           refid      st when poll reach  delay  offset  disp
-----
*host2.corp.com host121.corp.co  2   47  64  377   31.3   93.94   16.5
+host4.corp.com host2.corp.com   3  212 1024 377   33.8   89.58   16.9
 host8.corp.com host2.corp.com  16 never  64    0    0.0    0.00  64000
```

The last line of the previous example shows that `host8` is either not running NTP or cannot be reached.

To monitor the local host's NTP status using the `xntpd` command, use the following syntax:

```
xntpd [options...]
```

To monitor remote hosts' NTP status using the `xntpd` command, use the following syntax:

xntpdc [*options...*] *host1 host2...*

Note

The latest versions of the `xntpdc` command and `xntpd` daemon, delivered with NTP Version 4, are incompatible with previous versions of NTP. If you use the latest `xntpdc` command to collect information from an older `xntpd` daemon, or an older `xntpdc` command to collect information from the latest `xntpd` daemon, you will receive inconsistent results.

Table 12–2 shows some of the `xntpdc` command options.

Table 12–2: Options to the `xntpdc` Command

Option	Function
<code>-c subcommand</code>	Interprets <i>subcommand</i> as an interactive format command and adds it to a list of commands to be executed on the specified host or hosts.
<code>-i</code>	Forces <code>xntpdc</code> to operate in interactive mode.
<code>-l</code>	Prints a list of peers that are known to the server.
<code>-p</code>	Prints a list of peers and a summary of their state. This is similar in format to the <code>ntpq -p</code> command.

See `xntpdc(8)` for more information on this command and its subcommands.

The following example shows normal output from the `xntpdc` command with the `-p` option:

```
% xntpdc -p
      remote           refid      st when poll reach  delay  offset  disp
=====
*host2.corp.com host121.corp.co  2   47  64   377  31.3  93.94  16.5
+host4.corp.com host2.corp.com  3   212 1024  377  33.8  89.58  16.9
.host5.corp.com host12.usc.edu    2   111 1024  377  39.1  46.98  17.7
```

12.6 Querying Servers Running NTP

You can query time by using the `ntp` and `ntpdate` commands. However, it is best to use the `ntpdate` command because it works with all versions of NTP and provides additional features.

Mail System

The Tru64 UNIX mail system enables users to send mail to other users, whether on the same system, same network, or the other side of the world. This chapter describes:

- The Tru64 UNIX mail system and its components
- How to configure mail (the `sendmail` utility) on a standalone system or across an enterprise
- How to configure POP and IMAP mail
- How to administer mail on server and client systems

For additional introductory information on mail, see `mail_intro(7)`, the *sendmail* book by O'Reilly & Associates, and the *Sendmail Installation and Operation Guide* (provided in PDF format on the Tru64 UNIX Documentation CD-ROM). For troubleshooting information, see Section 15.18 for the `sendmail` utility and Section 15.19 for POP and IMAP mail.

The mail daemons in Tru64 UNIX are based on `sendmail` Version 8.9.3 from Sendmail, Inc, POP3 Version 2.5.3 from Qualcomm, Inc., and Cyrus IMAP4 Version 1.6.19 from Carnegie-Mellon University. If you need later versions of these packages than the operating system offers, you can obtain updated software directly from the aforementioned organizations or you can obtain the Open Source Internet Solutions (OSIS) product, a collection of popular Open Source software that Compaq distributes on a CD-ROM.

The OSIS kit usually contains more up-to-date versions of the Open Source software than the operating system because OSIS is updated and distributed several times a year. OSIS also contains an administration utility that allows you to easily configure advanced features of `sendmail`, including masquerading, virtual domains, anti-spam, and the Lightweight Directory Access Protocol (LDAP). For more information about the OSIS product, see the following URL:

<http://www.tru64unix.compaq.com/internet/detailed.htm>

13.1 Mail Environment

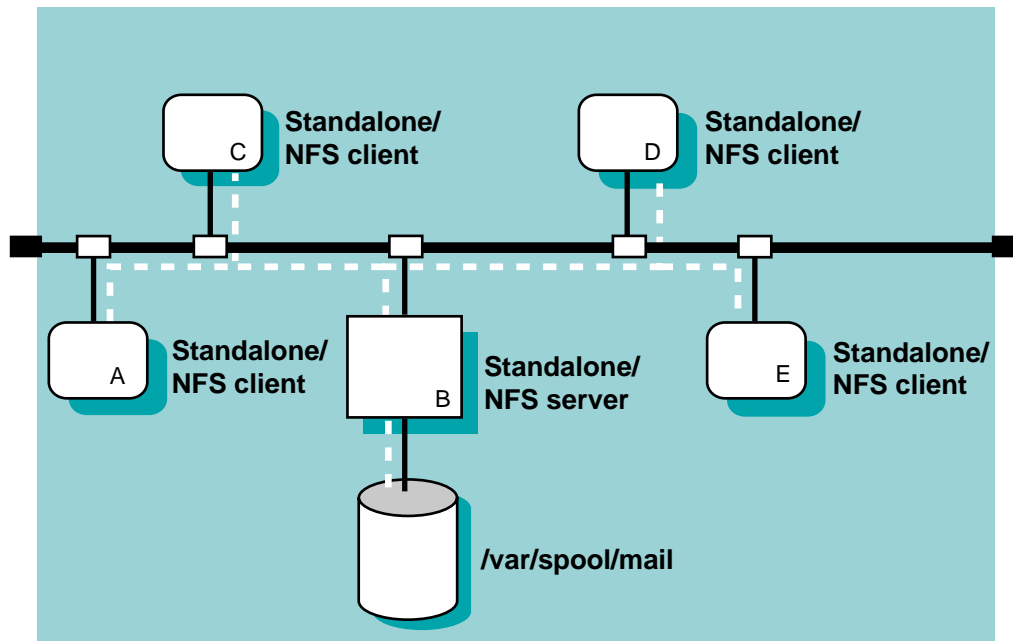

In the mail environment, systems can have the following roles:

- **Standalone** — A mail standalone system is one that processes, sends, and delivers mail locally. This is useful for configurations of from 1 to 6 systems. In small LAN configurations of two or more systems, one system serves the mailbox to the other systems using NFS. In this case, NFS must be configured on all systems.
- **Client** — A mail client system is a system that sends all of its mail to a mail server for processing and delivery. If the addressee is on the client system, the mail is delivered there. If not, the mail is forwarded to the destination system.
- **Server** — A mail server system is a system that receives mail from clients in a local domain for processing and delivery to other domains, the Internet, or other networks. In addition, the server also receives mail from other domains for delivery.

Figure 13-1 shows a sample standalone configuration on a LAN in which all hosts are configured as mail standalone systems. Host B is also an NFS server, exporting the `/var/spool/mail` directory to hosts A, C, D, and E. Hosts A, C, D, and E are also NFS clients, importing the `/var/spool/mail` directory from host B.

The hosts must also have identical information in their `passwd` and `aliases` files. This information can be distributed either by using NIS or by manually editing the files on each system.

Figure 13–1: Sample Mail Standalone Configuration

ZK-1156U-AI

Figure 13–2 shows a sample client/server configuration in which host B is configured as a mail server and hosts A, C, D, and E are configured as mail clients. This is useful in larger enterprise networks that consist of multiple domains and connections to the Internet or other networks.

This configuration also provides for the creation of a natural hierarchy of mail servers in large enterprise networks with multiple domains. Mail clients in each domain would direct all traffic to one or more mail servers, depending on the number of clients in the domain. Each domain's servers would then forward mail to the enterprise's top domain servers for forwarding to the Internet. Since almost all of your local domain's mail traffic goes through the servers, this simplifies administration and problem resolution in that you only have to manage the servers.

The connection to the Internet in Figure 13–2 could be direct or through a local access provider. Business configurations would typically use firewalls and dedicated mail servers. If using a firewall, ensure the firewall and the mail server are configured to work with each other. See the documentation for your firewall product for more information.

Figure 13–2: Sample Mail Client/Server Configuration

ZK-1157U-AI

If users need to send mail between systems that use different mail protocols, such as the Simple Mail Transfer Protocol (SMTP), UNIX-to-UNIX Copy Program (UUCP), and DECnet, it is best to designate specific server systems in your network to perform those functions. These server systems are also known as mail relays.

Additional mail configurations are possible, but they require more effort to plan for and to configure. See the *sendmail* book by O'Reilly and Associates and the *Sendmail Installation and Operation Guide* for more information.

In implementing a client/server mail environment, you need to decide how to do the following:

- Direct outgoing mail to the servers
- Handle incoming mail to the domain
- Deliver mail to clients
- Distribute the `aliases` file
- Distribute the `passwd` file
- Handle DECnet mail

This section describes each of these topics.

13.1.1 Directing Outgoing Mail to Servers

To direct outgoing mail to a server, you include the DNS mail exchanger (MX) entry in the `/etc/namedb/hosts.db` file. This entry specifies a system in the local domain that can deliver mail to other systems, especially those not directly connected to the local network. Using MX to route mail has the following benefits:

- You can define an MX record to point to all of the mail servers in your local domain. If a mail server is inaccessible, mail can be delivered to another host listed in the MX record.
- You can use MX records to define a system to be a mail exchanger for an inaccessible remote system. Then, if you send mail to the remote, inaccessible host, instead of being queued on your local system and periodically resent, the mail is sent to the mail exchanger and queued there until the host is restored.

For information on adding entries to the `/etc/namedb/hosts.db` file, see Section 8.9, Appendix H, and `bind_manual_setup(7)`.

13.1.2 Handling Incoming Mail to the Domain

To simplify the handling of incoming mail to a domain and to ensure reliability, use domain-based addresses in your environment. Mail sent over the Internet is usually addressed in the following format:

username@hostname.domain

For example: `joe@host1.nyc.big.com`

Using domain-based addresses, this address appears as follows:

`joe@nyc.big.com`

Mail is sent to the local domain `nyc.big.com` instead of to the specific host within that domain `host1.nyc.big.com`; the return address is also `@nyc.big.com`. Then, the mail servers within the local domain decide how to deliver the mail to the user's account.

Domain-based addresses make it easier to manage your mail environment. You can change your mail system (that is, move user accounts and replace or move systems) without disrupting your mail delivery. These changes are transparent to users sending mail to your systems.

13.1.3 Delivering Mail to Clients

Once mail is delivered to the domain, you can deliver it to clients using one of the following mechanisms:

- Deliver the mail to the `/var/spool/mail` directory on each client, which is the default
- Deliver the mail to the server and use NFS to serve the mail directory to each client
- Deliver the mail from a server to a local client machine using POP (see Section 13.4)
- Deliver the mail to a server using IMAP (see Section 13.5)

To deliver mail to each client, each server in the domain must have an `aliases` file that contains an entry for each user on the client. For example:

```
username1: username1@client1
username2: username2@client1
```

13.1.4 Distributing the aliases File

For standalone and server systems, use the Network Information System (NIS) to distribute the mail aliases file from one machine. In a LAN environment with standalone systems, distribute the mail aliases file from the NFS server system. In a client/server environment, distribute the `aliases` file to the servers in the domain. In any case, sharing the `aliases` file among systems simplifies administration in that you need to update only one aliases file, instead of several.

See `aliases(4)` for more information about the database. See Section 13.9 and Chapter 9 for information about distributing the database with NIS.

13.1.5 Distributing the passwd File

If you have multiple server systems in a domain, make sure that the information in the `passwd` file is identical on each system. For security reasons and to ensure correct mail delivery, it is best to do this by manually editing the `passwd` file on each server system.

13.1.6 Handling DECnet Mail

When you set up a mail server system, you must consider that the mail address formats for DECnet Phase IV and DECnet/OSI are different from those for TCP/IP. Therefore, you need to establish a mapping scheme to translate mail addresses when sending mail between a DECnet node and a TCP/IP node.

The mapping scheme used by the Tru64 UNIX version of the `sendmail` program for DECnet Phase IV encapsulates DECnet addresses inside a pseudomain. For example, a typical DECnet Phase IV address has the following format:

nodename::username

Mail addressed in this format is mapped to an address in the following format:

username@nodename.pseudodomain.top.domain

The variables represent the following:

username

The user name.

nodename

The DECnet node name.

pseudodomain

An arbitrary string that specifies the DECnet pseudodomain. The pseudodomain can be an arbitrary string, but it must be used consistently throughout your organization. All of your mail systems must be configured to use the same string for the pseudodomain.

top.domain

Usually, your company's domain name; for example, *abc.com*.

The mapping for DECnet/OSI uses a similar scheme. A typical DECnet/OSI address has the following format:

username@namespace.site.nodename

Mail addressed in this format is mapped as follows:

username@nodename.site.namespace.pseudodomain.top.domain

As with DECnet Phase IV, the pseudodomain can be an arbitrary string. However, if you use both DECnet Phase IV and DECnet/OSI within your organization, it is best to use different pseudodomain names.

Some environments that support both DECnet Phase IV and DECnet/OSI use the DECnet Phase IV syntax to handle DECnet-based mail. This simplifies the mail administration task. In order to implement this, all DECnet-OSI nodes must have a unique Phase IV Synonym and must be configured to use the Phase IV Synonym. You can reconfigure a DECnet/OSI host by typing the following command line:

```
# ncl set session control application mail111 Node Synonym=true
```

See the DECnet/OSI documentation for more information.

13.2 Planning Mail

This section describes those tasks you need to do before configuring mail.

13.2.1 Verifying that Required Protocols are Installed

Depending on the protocols supported by your mail server, verify that the following required subsets are installed and configured:

- DECnet
- DECnet/OSI
- X.25 (PSInet)
- UUCP

See the documentation for each product for installation and configuration instructions. For UUCP, verify that the UUCP subset is installed by entering the following command:

```
# setld -i | grep OSFUUCP
```

If it is not installed, install it by using the `setld` command. For more information on installing subsets, see `setld(8)`, the *Installation Guide*, or the *System Administration* manual.

13.2.2 Verifying that Required Services are Configured

The following table lists specific mail configurations and the network service required:

If you want to:	Configure this service:
Distribute the aliases file	NIS
Use domain-based addressing	DNS/BIND

If NIS is needed, enter the following command as root to verify that NIS is configured:

```
# rcmgr get NIS_CONF
```

If the command returns `NO`, then NIS is not configured. See Chapter 9 for instructions on how to configure NIS and distribute the `aliases` file.

If DNS is needed, enter the following command as root to verify that DNS is configured:

```
# rcmgr get BIND_SERVERTYPE
```

If the command returns nothing, then DNS is not configured. See Chapter 8 for instructions on how to configure DNS.

13.2.3 Preparing for the Configuration

After you install and configure the required protocols and services, you configure mail using the Mail Configuration application.

Mail configuration consists of:

- Defining the standalone, client, or server system
- Defining the protocol information (server systems only)

The following sections contain worksheets that you can use to record the information required to configure mail.

13.2.3.1 General System Information

Figure 13–3 shows the Basic Mail Setup Worksheet. If you are viewing this manual online, you can use the print feature to print a copy of this worksheet. The following sections explain the information you need to record on the worksheet.

Figure 13–3: Basic Mail Setup Worksheet

Basic Mail Setup Worksheet			
Mail server (clients only):	_____		
Top domain (servers only):	_____		
Mailbox directory:	<input type="checkbox"/> Local	<input type="checkbox"/> NFS client	<input type="checkbox"/> NFS server
Locking:	<input type="checkbox"/> lockf	<input type="checkbox"/> Lock file	<input type="checkbox"/> Both
Mailbox server:	_____		

Mail server (clients only)

The fully qualified name of your mail server; for example, `foo.dec.com`. Or, the name of your domain; for example, `dec.com`, if you are using domain-based routing. It is advantageous to specify the domain name itself because your mail service cannot be interrupted by a single mail server that becomes unavailable.

Top domain (servers only)

The name of the highest level domain in your organization that uniquely identifies your organization. For example, if the server domain name is `nyc.big.com`, the top domain is `big.com`. If the server domain name is `cs.big.univ.ac.uk`, the top domain is `big.univ.ac.uk`.

Mailbox directory

The location of the mailbox directory.

For standalone and client systems, if the mailbox directory is on the local system, check Local. If it is on a remote system and is to be mounted on the local system using NFS, check NFS Client. If the local system is to export mail boxes to NFS clients, check NFS Server.

For server systems, check Server to make the mailbox directories available to other systems. If you do not want to share the mailbox directories, check Local. In this case, use the `aliases` file to send each user's mail to the appropriate system. See Section 13.9 and `aliases(4)` for more information.

Locking

The type of file locking to use on the mailbox.

For standalone and client systems, if the host with the mailbox directory is a Tru64 UNIX system, check `lockf`; this provides the best performance. If you are not sure what operating system the host with the mailbox directory is running, check `Lock file`. If you want to use both, check `Both`.

Note

The locking mechanism you select must match the mechanism used by the NFS server. If you are not sure how the locking mechanisms are set on the NFS server, ask the administrator of the NFS server.

For server systems, if you checked `Local` as the mailbox location, check `lockf`. If you checked `Client` as the mailbox location, check `Lock file`. If you checked `Server` as the mailbox location, check `Both`.

Mailbox server

The name of the system that exports the mailbox to your local system.

13.2.3.2 Protocol Information

Figure 13–4 shows the Mail Protocol Worksheet. If you are viewing this manual online, you can use the print feature to print a copy of this worksheet. The following sections explain the information you need to record on the worksheet.

Figure 13–4: Mail Protocol Worksheet

Mail Protocol Worksheet	
Internet (SMTP)	Forward: <input type="checkbox"/> None <input type="checkbox"/> Internet <input type="checkbox"/> Nonlocal <input type="checkbox"/> Local
	Relay's host name: _____
	Relay's protocol: _____
	Pseudodomain: _____
	Pseudodomain aliases: _____
	Host aliases: _____
Others	Protocol: <input type="checkbox"/> DECnet <input type="checkbox"/> DECnet/OSI <input type="checkbox"/> POP3 <input type="checkbox"/> MTS <input type="checkbox"/> UUCP <input type="checkbox"/> X.25 <input type="checkbox"/> IMAP4
	Routing: <input type="checkbox"/> Internet <input type="checkbox"/> Direct <input type="checkbox"/> Relay
	Relay's host name: _____
	Relay's protocol: _____
	Node address (DECnet): _____
	DNS name space (DECnet/OSI): _____
	Pseudodomain: _____
	Pseudodomain aliases: _____
	Host aliases: _____

To configure your system as an Internet (SMTP) server, you need to collect the following information:

Forward

The type of mail that must be forwarded to a relay. If the local host has direct access to the Internet and does not forward any mail, check None. If the local host must forward all mail addressed outside of the top domain, check Internet. If the local host must forward all messages addressed outside of the local Internet domain, check Nonlocal. If the local host must forward all mail, including local domain mail, check Local.

Relay's host name

The name of the remote host that will process SMTP mail.

Relay's protocol

The name of the protocol the server uses to forward messages to the relay host.

Pseudodomain

An arbitrary string that specifies the pseudodomain for SMTP mail. The pseudodomain name must be unique for each protocol and must be used consistently throughout your enterprise.

Pseudodomain aliases

Any synonyms for your pseudodomain.

Host aliases

The alternative names that other systems might use to direct mail to your host.

To configure your system as a server for other mail protocols, you need to collect the following information:

Protocol

The type of mail protocols to use. Available protocols include the following:

- DECnet (Phase IV)
- DECnet/OSI (Phase V)
- Internet Mail Protocol (SMTP) (required)
- Internet Message Access Protocol (IMAP)
- Message Transport System (MTS)
- Post Office Protocol (POP)
- UUCP
- X.25 (PSInet)

Routing

For DECnet, DECnet/OSI, UUCP, MTS, and X.25 only. If mail for the particular protocol is to be forwarded over the Internet to an unspecified gateway, check Internet. The Internet depends on DNS to select an appropriate relay; therefore, do not specify a relay hostname for the Internet.

If the particular protocol is installed on this server, check Direct. If mail requiring the particular protocol is to be forwarded to another system for processing, check Relay. Complete the Relay's hostname and Relay's protocol fields.

Relay's host name

The name of the remote host that will process mail for the protocol.

Relay's protocol

The name of the protocol the server uses to forward messages to the relay host.

Node address (DECnet)

The address for this machine (DECnet only).

DNS name space (DECnet/OSI)

The complete DNS name space name for this node (DECnet/OSI only). The syntax of the DNS name space is as follows:

namespace::site.nodename

Pseudodomain

An arbitrary string that specifies the pseudodomain (DECnet, DECnet/OSI, and MTS only). The pseudodomain name must be unique for each protocol and must be used consistently throughout your enterprise.

Pseudodomain aliases

Any synonyms for your pseudodomain (DECnet, DECnet/OSI, UUCP, and MTS only).

Host aliases

The alternative names that other systems might use to direct mail to your host.

13.3 Configuring Mail

Use the Mail Configuration application of the Common Desktop Environment (CDE) Application Manager to configure mail on systems with graphics capabilities.

Note

Alternatively, you can use the SysMan Menu (`/usr/sbin/sysman-accel mail`) or the `mailsetup` utility to configure mail on

your system. See the online help and `mailsetup(8)` for more information.

You can configure the following systems:

- Standalone systems
- Client systems
- Server systems

To start the Mail Configuration application, do the following:

1. Log in as root.
2. Click on the Application Manager icon on the CDE desktop.
3. Double-click on the System_Admin application group icon.
4. Double-click on the Configuration application group icon.
5. Double-click on the Mail Configuration application icon in the Configuration group. The Mail Configuration main window is displayed, showing available Mail service types and configured Mail service types.

To exit the Mail Configuration application, choose File then Exit. See `mailconfig(8)` for more information.

The Mail Configuration application has an extensive online help system that you can use, instead of the instructions in this section, to configure mail on your system.

13.3.1 Configuring a Standalone Mail System

To configure mail for a standalone system, do the following:

1. Select Standalone from the Available Mail Service Types list box in the Mail Configuration window
2. Select Configure to display the Standalone Setup dialog box.
3. Select Mailbox Setup to display the Mailbox Setup dialog box if your site uses NFS to import or export system mailbox directories (for instance, `/var/spool/mail`); otherwise, go to step 7, the default settings are applicable for your mail configuration.
4. If your system imports its mailbox using NFS, select the NFS Client radio button and do the following:
 - a. Enter the server name in the Mailbox Server field.
 - b. Select a radio button for the appropriate Locking mechanism: lockf, Lock Files, or Both.

5. If your system distributes mailboxes to NFS clients, select the NFS Server radio button, then select the Both radio button for the Locking Mechanism setting.
6. Select OK to complete the mailbox setup and close the Mailbox Setup dialog box.
7. Select Commit to save the changes. You are asked if you would like to restart the `sendmail` daemon.
8. Select Restart to start the `sendmail` daemon and apply your changes immediately. Or, select No to apply the changes the next time you reboot your system.
If you choose Restart, you are informed that the `sendmail` daemon has been started. Select OK to dismiss the message.
9. Select Close to close the Standalone Setup dialog box.

13.3.2 Configuring a Mail Client

To configure a mail client, do the following:

1. Select Client from the Available Mail Service Types list box in the Mail Configuration window.
2. Select Configure to display the Client Setup dialog box.
3. Enter the name of a mail server for outgoing mail in the Mail Server field.
4. Select Mailbox Setup to display the Mailbox Setup dialog box.
5. Select the NFS Client radio button for the Mailbox Directory if your site uses NFS to share system mailbox directories; otherwise, select Local and go to step 7.
6. Enter the name of the server that exports the mailbox directory to your system in the Mailbox Server field.
7. Select a radio button for the appropriate Locking mechanism: lockf, Lock Files, or Both.
8. Select OK to complete the mailbox setup and to close the Mailbox Setup dialog box.
9. Select Commit to save the changes. You are asked if you would like to restart the `sendmail` daemon.
10. Select Restart to start the `sendmail` daemon and apply your changes immediately. Or, select No to apply the changes the next time you reboot your system.

If you choose Restart, you are informed that the `sendmail` daemon has been started. Select OK to dismiss the message.

11. Select Close to close the Client Setup dialog box.

13.3.3 Configuring a Mail Server

To configure a mail server, follow these steps. If you intend to implement the POP or IMAP daemons, configure SMTP and other necessary protocols first, then see Section 13.4 and Section 13.5.

1. Select Server from the Available Mail Service Types list box in the Mail Configuration window.
2. Select Configure to display the Server Setup dialog box.
3. Select the mail protocol you want to configure from the Available Protocols list box. The Internet Mail Protocol (SMTP) protocol is the only required protocol configuration. Configure additional protocols as necessary.
4. Select Configure to display the protocol setup dialog box for the protocol you selected.
5. For the SMTP protocol, select the type of forwarding for this server. If you select None, go to step 11; otherwise, go to step 7.
6. For the DECnet, DECnet/OSI, MTS, UUCP, and X.25 protocols, select a Routing type. If you select Internet or Direct, go to step 9. If you select Relay, go to step 7.
7. Enter a host name in the Relay's Hostname field if you will be forwarding mail to another system for processing; otherwise, continue with step 9.
8. Select the protocol used to communicate with the relay in the Relay's Protocol pulldown menu.
9. For the DECnet, DECnet/OSI, and MTS protocols, in the Pseudo Domain field, enter the domain name used to identify mail that requires the selected protocol.
10. For the DECnet, DECnet/OSI, MTS, UUCP, and X.25 protocols, to add aliases for the pseudodomain, select Pseudo Domain Aliases to display the Pseudo Domain Aliases dialog box, and do the following:
 - a. Enter the alias name in the Pseudo Domain Alias field and select Add.
 - b. Repeat the previous step as many times as necessary.
 - c. Select OK to close the Pseudo Domain Aliases dialog box.

11. To add aliases for this mail server, select Host Alias to display the Host Aliases dialog box, and do the following:
 - a. Enter the alias name in the Host Alias field and select Add.
 - b. Repeat the previous step as many times as necessary.
 - c. Select OK to close the Host Aliases dialog box.
12. For the DECnet protocol, enter the DECnet node address (area.node) for this server in the Node Address field, for example, 32.958.
13. For the DECnet/OSI protocol, enter the name space of the node, which is usually the token before the colon (:) in a DECnet Phase V address, in the DNS Name Space field.
14. Select OK to close the Setup dialog box for the protocol you selected. The Server Setup dialog box is active.
15. Configure another protocol if necessary. Repeat steps 3 through 15 for each additional protocol.
16. Select Mailbox Setup to display the Mailbox Setup dialog box.
17. Select a radio button for Mailbox Directory.

If your site does not use NFS to distribute the system mailbox directories, select Local instead of NFS Server, and then go to step 19.
18. If you selected NFS Client as a Mailbox Directory, enter the name of the mail server in the Mail Server field. Be sure to include the domain. For example, for a server named mailhub, the server name with domain might be mailhub.nyc.dec.com.
19. Select a radio button for the appropriate Locking mechanism: lockf, Lock Files, or Both.
20. Select OK to complete the mailbox setup and close the Mailbox Setup dialog box.
21. Select Commit to save the changes. You are prompted to restart the `sendmail` daemon.
22. Select Restart to start the `sendmail` daemon and apply your changes immediately. Or, select No to apply the changes the next time you reboot your system.

If you choose Restart, you are informed that the `sendmail` daemon has been started. Select OK to dismiss the message.
23. Select Close to close the Server Setup dialog box.
24. Add DNS mail exchanger (MX) records to the `/etc/namedb/hosts.db` file for each host in your environment, if necessary. See Section 13.1.1 for more information.

13.3.4 Adding a New Mail Host

To add a new mail host to your existing mail environment, do the following:

1. Configure the network and network services on the host. See Chapter 2 for more information.
2. If you are using DNS MX records in your environment, update the DNS data files. See Section 13.1.1 for more information.

13.4 Post Office Protocol

The Post Office Protocol Version 3 (POP3 or POP) is a client/server protocol that allows users to download their Email from a mail server to a remote client. It is intended for users that mainly access their Email in an offline mode. In offline mode, messages are delivered to a server and reside there until the user connects to the server and downloads the incoming messages to the client machine (a desktop or laptop computer running Windows, Macintosh, UNIX, or another operating system). Thereafter, all message processing is local to the client machine and environment. This is the mode used widely today by Internet Service Providers (ISP) to provide Email services for their consumers. See `pop3d(8)` for further information.

13.4.1 Installing POP

The operating system provides a POP3 server (`/usr/sbin/pop3d`) from Qualcomm, Incorporated, which is fully installed and configured for you when you install the `OSFINET` subset (check the installation log file for any warnings or errors). The `pop3d` daemon is configured to listen on port 110 for incoming connections, and allows any user of the system to access their Email via a POP client.

During installation, the `/etc/passwd`, `/etc/services`, and `/etc/inetd.conf` configuration files are updated. If the lines displayed in the following examples are not present in the configuration files, the POP3 service may not behave appropriately. If a previous version of POP was detected, or if the `OSFINET` subset did not install properly, the files might not have been updated and the changes must be made manually.

The `/etc/passwd` file must contain the following line; if it does not, add the line to the file:

```
pop:*:13:6:POP Mail Service Account:/:
```

If necessary, change the user identification number, 13, to a value that is appropriate for your system.

The `/etc/services` file must contain the following line; if it does not, add the line to the file:

```
pop3    110/tcp
```

The `/etc/inetd.conf` file must contain the following line; if it does not, add the line to the file:

```
pop3    stream  tcp    nowait  root    /usr/sbin/pop3d    pop3d
```

13.4.2 Migrating to the New POP3 Implementation

The POP service was upgraded in Tru64 UNIX Version 5.0. Migration paths are provided for systems that were running either the version of POP3 offered with the `OSFMH` (RAND Corp. Mail Handler) subset or the Qualcomm POP3 service (if your version came directly from Qualcomm).

If you use the MH POP3 service, you must migrate your POP user accounts from the `/usr/spool/pop/POP` file to the `mailauth` database and convert your mailboxes to the new format.

If you use the Qualcomm POP3 service, you must migrate your POP user accounts from the `popauth` database to the `mailauth` database; however, you do not need to convert your mailboxes. The only difference between Qualcomm POP3 and the Tru64 UNIX implementation of Qualcomm POP3 is the mail authorization database, which has been enhanced to store secondary POP and IMAP passwords.

The following sections describe the migration paths for each service. See `popcv(8)` for further information.

13.4.2.1 Migrating from MH POP3

To transition from MH POP3 service to the new implementation, complete the following tasks:

1. Remove any startup scripts for the `/usr/lib/mh/popd` file in the `/sbin/rc` directories.
2. Make sure that the `/etc/inetd.conf` and `/etc/services` configuration files were updated with the correct entries as described in Section 13.4.1.
3. Initialize the `mailauth` database by entering the following command:

```
# /usr/bin/mailauth -init
```
4. Use the `popcv` utility to move usernames and passwords from the `/usr/spool/pop/POP` file to the `mailauth` database (`/etc/pop.auth.pag` and `/etc/pop.auth.dir`). Enter the following command, where `filename` can be an alternate file used to store POP passwords:

```
# /usr/bin/popcv [filename]
```

5. Use the `mailcv` tool to convert existing MH POP3 mail folders to the new POP3 format:

- a. Change directory to the MH POP3 mail folder directory:

```
# cd /usr/spool/mail/POP
```

The directory might be `/usr/spool/pop` or another directory depending on how you configured MH POP3.

- b. For each mail user, enter the following command, where `input` is the file name of the user's MH POP3 folder:

```
# /usr/dt/bin/mailcv -Q -f input
```

Typically, the file name is the same as the POP user's username. For instance, for a user named Jake, you would convert the `/usr/spool/mail/POP/jake` file.

Optionally, you can change the name of a mail folder during the conversion process by appending the new file name to the end of the command, as in the following example:

```
# /usr/dt/bin/mailcv -Q -f charlie chuck
```

See `mailcv(1)` for more information.

13.4.2.2 Migrating from Qualcomm POP3

To transition from Qualcomm's POP3 service to the new implementation, complete the following tasks:

1. Ensure that the `/etc/inetd.conf` and `/etc/services` configuration files were updated with the correct entries as described in Section 13.4.1.
2. If a previous `popauth` database exists, convert it to a `mailauth` database by using the following command:

```
# /usr/bin/mailauth -convert
```

Note that you need to convert your mail folders only if you previously ran the MH POP3 server.

13.4.3 Configuring a POP Mail Account

To configure a POP mail account, create a UNIX account for the user (if one does not already exist) as described in the *System Administration* guide. The user's mailbox is set up automatically.

Once the user's account is set up on the server, the user can configure a mail application compatible with POP3, for example, Netscape Communicator, which is bundled with the operating system software. At a minimum, you

must provide the user with the following information about mail service in your facility:

- POP username — Specify if different from the UNIX username
- POP-specific password — Specify if different from the UNIX password
- POP server name — The mail application collects incoming mail from this server
- SMTP server name — The mail application delivers outgoing mail to this server
- Domain name — The mail application adds this domain name to all unqualified addresses for domain-based mail addressing

13.4.4 Changing Login Authentication

The POP service typically authenticates user accounts by verifying the supplied user name and password against information in the UNIX password file (usually the `/etc/passwd` file). The Tru64 UNIX implementation of POP has been enhanced to optionally support SIA interfaces for authentication on a C2 secure system.

For increased security, the system administrator can have POP users use alternate passwords instead of their usual login passwords; therefore, if a POP password is compromised across the network, system access is not at risk.

There are two ways to enable alternate passwords for POP authentication:

- Arrange for POP users to store alternate passwords in the `mailauth` database (`/etc/pop.auth.dir` and `/etc/pop.auth.pag`).
- Add mail users to the same `mailauth` database as Authenticated POP (APOP) users. APOP uses an encrypted authentication mechanism, also with alternate passwords, that is more secure than standard POP; however, users need mail client applications compatible with APOP to take advantage of it.

Use the SysMan Menu application of the Common Desktop Environment (CDE) Application Manager to enable either authentication option. To invoke the SysMan Menu application, follow the instructions in Chapter 1, then follow these steps:

Note

If users in your environment use one of the old POP3 implementations, you must migrate them to the new POP3

implementation as described in Section 13.4.2 prior to enabling alternate passwords.

1. From the SysMan Menu, select Mail→Manage users' mail accounts. The Mail User Administration window is displayed. Optionally, you can invoke this utility by executing the following command:

```
# mailusradm &
```

2. Select the radio button for List Specific Users and select Compile List.
3. Enter the username or a wildcard in the dialog box and select OK.
4. Select the name of the user for whom you would like to require an alternate password.
5. Select the desired mail service type from the pulldown menu. To require that the user use an alternate password for POP mail, select POP with Mail Password. To switch the user's mail service to APOP, select APOP with Mail Password.
6. Select OK to save your changes.
7. Enter an alternate password for POP or APOP and select OK.

The user can later set a new password by issuing the `mailauth` command without any flags. For example:

```
% /usr/bin/mailauth
```

8. Select OK to dismiss the message that indicates that the account has been modified successfully.
9. Select Exit to close the Mail User Administration window.

If you need to change authentication for multiple accounts, you can select List All Local Mail Users in step 2. Use the Control key in combination with a right-mouseclick to select more than one user name from the list. See `mailusradm(8)` for more information about the Mail User Administration utility.

Optionally, you can use the `mailauth` utility to set up authentication. See `mailauth(8)`.

13.4.5 Administrative Tools

You can use the following tools to administer the POP service:

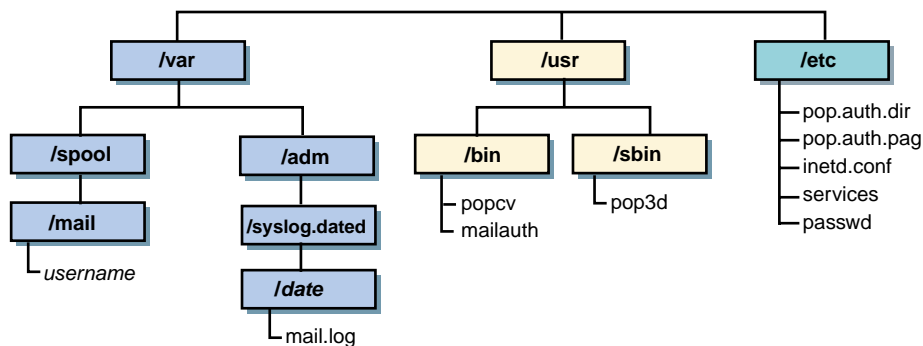

- `mailauth` — Utility used to manage the secondary mail authorization database. See `mailauth(8)`.
- `mailusradm` — System administration GUI utility used to configure mail users. See `mailusradm(8)`.

The POP server sends log messages to the `syslogd` daemon. The log information is stored in the `/var/adm/syslog.dated/date/mail.log` file. You can use this data to solve problems. The severity levels are NOTICE for failed and successful authentications and DEBUG for all debugging information.

13.4.6 Directory Structure

The POP configuration and mail files are distributed across the file system as indicated in Figure 13–5.

Figure 13–5: POP Directory Structure

ZK-1540U-AI

Table 13–1 describes the purpose of these files and directories.

Table 13–1: POP3 Files and Directories

File or Directory	Purpose
<code>/etc/passwd</code> file	Contains account information for each user on the system. Users configured in this file are able to use POP mail by default.
<code>/etc/pop.auth.*</code> files	Contain the encrypted mail authorization database, which is used to authenticate POP and IMAP users. See <code>mailusradm(8)</code> and <code>mailauth(8)</code> for information about editing this database.
<code>/var/spool/mail</code> directory	Contains the mail folders for all POP and UNIX mail users on the system. Each folder is a file with a file name that is usually identical to the user's login name.

13.5 Internet Message Access Protocol

The Internet Message Access Protocol Version 4 (IMAP4 or IMAP) is a client/server protocol that allows mail clients to access mail messages on a server. With it, the user can access mail folders and manipulate the contents remotely without having to log in to the server. The protocol allows clients to create, delete, and rename mail folders, to check for new messages and remove old messages, and to selectively retrieve messages for local viewing. In addition, the user can select messages by attributes and parse messages in the RFC 822 and MIME formats.

This protocol can be used in the offline, online, or disconnected mode. The offline mode is the same as that described in Section 13.4. In online mode, messages are manipulated on the server remotely by mail client programs. In disconnected mode, a mail client connects to the mail server, makes a cache copy of selected messages, and then disconnects from the server, later to reconnect and resynchronize with the server. In both online and disconnected access modes, mail is stored on the server, which is often a necessity for people who use different computers at different times to access their messages.

See `imapd(8)`, `deliver(8)`, and `imapd.conf(4)` for further information.

13.5.1 Installing IMAP

The operating system software includes the Cyrus IMAP4 Revision 1 server (`/usr/sbin/imapd`) by Carnegie Mellon University, which is installed and configured when you install the `OSFINET` subset (check the installation log file for any warnings or errors). The `imapd` daemon is configured to listen on port 143 for incoming connections.

During installation, the `/etc/passwd`, `/etc/services`, and `/etc/inetd.conf` configuration files are updated. If the lines specified in the following examples are not present in the configuration files, the IMAP service may not behave appropriately.

The `/etc/passwd` file must contain the following line; if it does not, add the line to the file:

```
imap:*:14:6:IMAP Mail Service Account:/:
```

If necessary, change the user identification number, 14, to a value that is appropriate for your system.

The `/etc/services` file must contain the following line. If it does not, add the line to the file:

```
imap      143/tcp
```

The `/etc/inetd.conf` file must contain the following line. If it does not, add the line to the file:

```
imap    stream  tcp    nowait  imap    /usr/sbin/imapd    imapd
```

13.5.2 Upgrading IMAP

Starting with Version 1.6.1 of the Cyrus IMAP4 Revision 1 server, the IMAP files in the `quota` and `user` configuration directories, and optionally, the users' mail directories in the IMAP mail spool, are stored in subdirectories a through z, sorted by the first character of each user name. This arrangement reduces the number of entries in a given directory and consequently increases performance and scalability.

If you are running the IMAP server from a previous version of the operating system, and you are upgrading to Tru64 UNIX Version 5.1, you must convert your `quota` and `user` configuration directories to the new format. Optionally, you can sort your IMAP mail spool in the same manner by enabling the `hashimapspool` option in the `/etc/imapd.conf` file before converting your configuration directories. See `imapd.conf(4)` for more information.

To convert your directories to the new format, use the `dohash` utility. See `dohash(8)` for more information.

13.5.3 Configuring IMAP Mail Accounts

To enable users to receive IMAP mail, you must complete two tasks. First, if the users do not have accounts on the system, you must create them. See the *System Administration* guide and `adduser(8)` for more information.

Second, you must change the properties of the users' accounts to indicate that their mail is to be processed by the IMAP server. Use the SysMan Menu application of the Common Desktop Environment (CDE) Application Manager to configure the user's mail service type. To invoke the SysMan Menu application, follow the instructions in Chapter 1.

To change the user's mail service type, do the following:

1. From the SysMan Menu, select Mail→Manage users' mail accounts. The Mail User Administration window is displayed. Optionally, you can invoke this application by executing the following command:

```
# mailusradm &
```

2. Select the radio button for List Specific Users and select Compile List.
3. Enter the username or a wildcard in the dialog box and select OK.

4. Select the name of the user whose mail service type you would like to change from the list.
5. Select the desired mail service type from the pulldown menu. To require that the user use an alternate password for IMAP mail, select IMAP with Mail Password. Otherwise, select IMAP to use the same password.

If you enable this option, the alternate passwords are stored in the mailauth database, which is located in the `/etc/pop.auth.dir` and `/etc/pop.auth.pag` files. See `mailauth(8)` for more information.
6. Select OK to save your changes.
7. Enter the mail administrator's password. In most cases, this password is the same as the root account password. Select OK.
8. Select the privileges to set on the user's mailbox. In most cases, you will select All to allow the user to read, modify, and delete messages in the mailbox. Select OK.

If you did not select IMAP with Mail Password in step 5, skip to step 10.
9. Enter an alternate password for IMAP and select OK.

The user can later select a new password by issuing the `mailauth` command without any flags. For example:

```
% /usr/bin/mailauth
```
10. Select OK to dismiss the message that indicates that the account has been modified successfully.
11. Select Exit to close the Mail User Administration window.

If you need to set up multiple IMAP accounts, you can select List All Local Mail Users in step 2. Use the Control key in combination with a right-mouseclick to select more than one user name from the list.

See the online help and `mailusradm(8)` for more information.

Once a user's IMAP account is set up on the server side, the user can configure a mail application compatible with IMAP4, for example, Netscape Communicator, which is bundled with the operating system software. At a minimum, you must provide the user with the following information about mail service in your facility:

- IMAP username — Specify if different from the UNIX username
- IMAP password — Specify if different from the UNIX password
- IMAP Mailbox location prefix — `user.username`
- IMAP server name — The mail application collects incoming mail from this server

- SMTP server name — The mail application delivers outgoing mail to this server
- Domain name — The mail application adds this domain name to all unqualified addresses for domain-based mail addressing

13.5.4 Migrating Users from UNIX and POP3 Mail

To convert an existing UNIX or POP3 mail user to IMAP mail, you must first set up the user's IMAP account as described in Section 13.5.3. Then, use the `mailcv` tool to convert the user's mail folder to the IMAP format as follows:

Note

If you are using MH POP3 or a version of Qualcomm POP3 that did not come with the operating system software, follow the instructions in Section 13.4.2 to convert to the new POP3 implementation before converting to IMAP.

1. Change directory to the UNIX/POP3 mail folder directory:

```
# cd /usr/spool/mail
```

2. Assume the user's identity by using the `su` command, as follows:

```
# su username
```

You must be the user to convert the user's mail folder to IMAP format with the `mailcv` command.

3. Enter the following command, where *folder* is the file name of the user's mail folder:

```
% /usr/dt/bin/mailcv -I -f folder
```

You need the user's IMAP password to use this command.

The mail folder file name is usually the same as the user's username. For instance, for a user named Jake, you would convert the `jake` file.

Optionally, you can move the converted messages to an IMAP subfolder during the conversion process by appending a subfolder name to the end of the command, as in the following example:

```
# /usr/dt/bin/mailcv -I -f charlie business
```

IMAP subfolders are described in Section 13.5.7. See `mailcv(1)` for more information about the `mailcv` command.

4. Exit the `su` session to the user's account, as follows:

```
% exit
#
```

Note that mail received after the account is changed to IMAP but prior to the conversion process is not lost. The newly-converted messages are appended to the existing messages in the user's mailbox.

Once a user's UNIX or POP account is converted to an IMAP account on the server, the user must reconfigure the mail application. Ensure that the user has a mail application compatible with IMAP4, for example, Netscape Communicator, which is bundled with the operating system software.

You also need to provide the user with information about mail service in your facility, as specified in Section 13.5.3.

13.5.5 Administrative Tools

You can use the following tools to administer the IMAP server:

- `cyradm` — Command line utility used for configuring and managing users, folders, subfolders, and so on. See `cyradm(1)`.
- `deliver` — Utility used to deliver mail to an IMAP mailbox. See `deliver(8)`.
- `dohash` — Utility used to convert the IMAP configuration directories from the format for older versions of the Cyrus IMAP4 Revision 1 server to the new format for Version 1.6.1 or higher. Another utility, `undohash`, reverses the process. See `dohash(8)`.
- `imapquota` — Utility used to report and fix IMAP mail quota usage. See `imapquota(8)`.
- `mailauth` — Utility used to manage the secondary mail password database. See `mailauth(8)`.
- `mailusradm` — System administration GUI utility used to configure mail users. See `mailusradm(8)`.
- `reconstruct` — Utility used to rebuild IMAP mailboxes. See `reconstruct(8)` for further information.

The IMAP server software sends log messages to the `syslogd` daemon. The log information is stored in the `/var/adm/syslog.dated/date/mail.log` file. You can use this data to solve problems. The severity levels are as follows:

NOTICE	Authentications, both successful and unsuccessful.
ERR	I/O errors, including failure to update quota usage. The message includes the specific file and UNIX error.

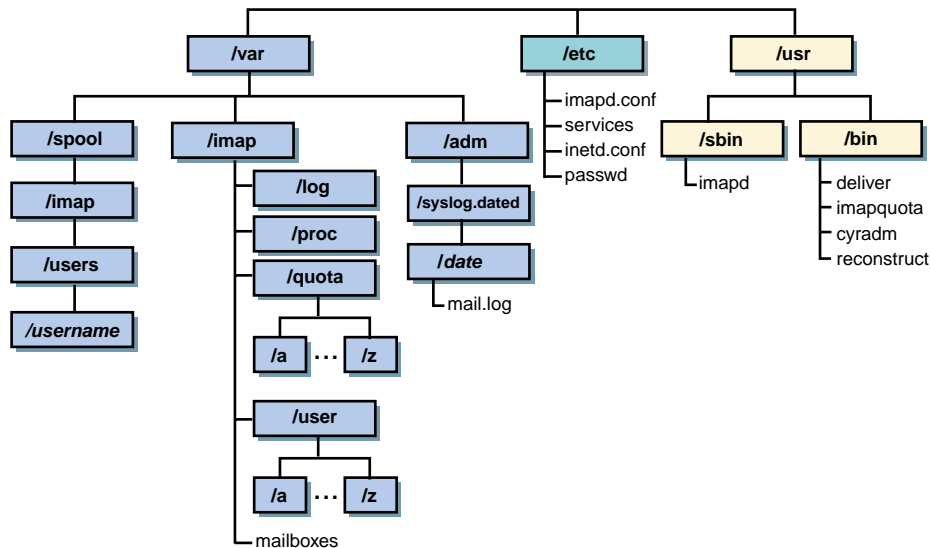

WARNING Protection mechanism failures, client inactivity timeouts.

INFO Mailbox openings.

13.5.6 Directory Structure

The IMAP configuration and mail files are distributed across the file system as indicated in Figure 13–6.

Figure 13–6: IMAP Directory Structure

ZK-1541U-AI

All of the runtime configuration information is stored in the `/etc/imapd.conf` file. This file contains site configuration and policy options, such as:

- Location of the configuration directory
- Partition names and their corresponding directory roots
- Threshold for quota warning messages
- Whether or not to allow anonymous logins
- Whether or not to automatically create `INBOX` mailboxes for users

See `imapd.conf(4)` for further information.

The configuration directory specified in the `/etc/imapd.conf` file contains the items listed in Table 13–2.

Table 13–2: Configuration Directory Contents

File or Directory	Purpose
<code>mailboxes</code> file	<p>Contains a sorted list of each IMAP mailbox on the server along with mailboxes quota root and access control list (ACL), described in Section 13.5.9 and Section 13.5.8, respectively. Because the ACL is security-critical information that cannot be reconstructed from information stored elsewhere, there is no utility to recover from a damaged <code>mailboxes</code> file.</p> <p>To protect the contents of the mailboxes, make frequent (even hourly) backups of the <code>mailboxes</code> file to some other part of the disk.</p>
<code>user/a...z</code> directories	<p>Contain user subscriptions. There is one file per user, each file containing a sorted list of the user's mailboxes.</p> <p>Each file name consists of the user's user name followed by a <code>.sub</code> file extension, and the files are sorted into the <code>a</code> through <code>z</code> directories by the first letter of the user name.</p> <p>There is no utility for recovering damaged subscription files. You can restore lost files from backups.</p>
<code>proc</code> directory	<p>Contains one file per active server process. The filename is the ASCII representation of the process id, and the file contains the following tab-separated fields:</p> <ul style="list-style-type: none">• Host name of client• Username, if logged in• Selected mailbox, if mailbox selected <p>The <code>proc</code> subdirectory is normally purged when you reboot the server.</p>

Table 13–2: Configuration Directory Contents (cont.)

File or Directory	Purpose
quota/a...z directories	<p>Contain quota specifications for restricted IMAP users. There can be multiple files for each user, each file containing the limit for a quota root, as described in Section 13.5.9.</p> <p>Each file name consists of the string <code>user</code> followed by one or more extensions, starting with the associated user name (for example, <code>user.hansen</code>). The files are sorted into the <code>a</code> through <code>z</code> directories by the first letter of each user name.</p> <p>The <code>imapquota</code> program, when invoked with the <code>-f</code> switch, recalculates each user's quota. To remove the restrictions on a user's quota, remove the user's quota file. Then run <code>imapquota -f</code> to make the quota files consistent again.</p>
log directory	<p>Contains zero or more subdirectories, each named after a user. If a subdirectory exists for a user, the server keeps a telemetry log of protocol sessions authenticating as that user. The telemetry log is stored in the subdirectory with a filename that matches the server's process ID. Use this feature only for debugging purposes; the log files grow rapidly.</p>

The largest database in the IMAP server is a user's mailbox directory. By default, these mailbox directories are located in the `/var/spool/imap/users` directory. There is one directory for each user and the directory name is the user's user name. If you have a highly populated mailbox tree, you can optionally sort these mailbox directories into `/var/spool/imap/users/a...z` subdirectories by specifying the `hashimapspool` option in the `imapd.conf` file. See `imapd.conf(4)` and `dohash(8)` for more information.

Each user's directory contains the files listed in Table 13–3.

Table 13–3: Mailbox Directory Contents

File or Directory	Purpose
message files	Contain one message each in RFC 822 format. Lines in the message are separated by a carriage return and line feed, not just a line feed. The file name of each message is the message's UID followed by a dot (.).
cyrus.header	Contains a magic number and variable-length information about the mailbox itself.
cyrus.index	Contains fixed-length information about the mailbox itself and each message in the mailbox.
cyrus.cache	Contains variable-length information about each message in the mailbox.
cyrus.seen	Contains variable-length state information about each user who has permission to read the mailbox.

The `reconstruct` utility can be used to recover from corruption in mailbox directories. If the `reconstruct` utility finds existing header and index files, it attempts to preserve any data in them that is not derivable from the message files themselves, including the flag names, flag state, and internal date. The utility derives all other information from the message files.

You can recover from a damaged disk by restoring message files from a backup and then running the `reconstruct` utility to regenerate what it can of the other files. The `reconstruct` program does not adjust the quota usage recorded in any quota file. After running `reconstruct`, run `imapquota -f` to fix the quota root files.

13.5.7 Mailbox Namespace

The IMAP server presents mailboxes using the `netnews` namespace convention. Mailbox names have the following restrictions:

- Are case-sensitive
- Cannot start or end with a period (.) character
- Cannot contain two period (..) characters in a row
- Cannot contain non-ASCII characters, shell metacharacters, or a backslash (/) character

All personal mailboxes for a user begin with the `user.username.` string. For example, mailboxes belonging to a user named Hansen begin with the `user.hansen.` string. If Hansen has a mailbox for work-related Email, it might be called `user.hansen.work.`

In the user's mail application, the prefix `user.hansen.` normally appears as `INBOX.`. The mailbox `user.hansen.work` would therefore appear as `INBOX.work`. However, if the access control list (ACL) of the mailbox permitted other users to see that mailbox, it would appear to them as `user.hansen.work`.

You can create or delete a user's mailbox by creating or deleting the user's `INBOX`. A user with an `INBOX` can create and subscribe to personal mailboxes. Users with dots in their user names are able to log in, but cannot have an `INBOX` or receive IMAP mail. When you delete a user's `INBOX`, all of the personal mailboxes associated with it are deleted as well.

With the exception of `INBOX`, all mailbox names are system-wide; they refer to the same mailbox regardless of the user. ACLs determine which users can access or see certain mailboxes.

In contexts that permit relative mailbox names, the mailbox namespace works as follows:

- Names that do not start with a period (.) are fully qualified.
- Names that start with a period (.) are relative to the current context.

You might need to use this convention if you use the `telnet` command to connect to an IMAP port for troubleshooting purposes or if you create an application that issues IMAP calls.

If you are working with folder names and the top of the hierarchy is named `user.hansen`, the name `.work.personnel.issues` resolves to `user.hansen.work.personnel.issues` and the name `work.personnel.issues` resolves to `work.personnel.issues`.

13.5.8 Access Control Lists

Access to each mailbox is controlled by each mailbox's access control list (ACL). ACLs provide a mechanism for specifying the users or groups of users who have permission to access the mailboxes.

An ACL is a list of zero or more entries. Each entry has an identifier and a set of rights. The identifier specifies the user or group of users to which the entry applies. The set of rights is one or more letters or digits, each letter or digit conferring a particular privilege. See `cyradm(1)` for further information.

Access rights are defined as follows:

lookup (1)

The user can see that the mailbox exists.

read (r)

The user can read the mailbox. The user can select the mailbox, retrieve data, perform searches, and copy messages from the mailbox.

seen (s)

The per-user seen state is preserved. The server saves the `Seen` and `Recent` flags for the user.

write (w)

The user can modify flags and keywords other than `Seen` and `Deleted` (which are controlled by other sets of rights).

insert (i)

The user can insert new messages into the mailbox.

post (p)

The user can send mail to the submission address for the mailbox. This right differs from the `i` right in that the delivery system inserts trace information into submitted messages.

create (c)

The user can create new sub-mailboxes of the mailbox.

delete (d)

The user can store the `Deleted` flag, perform expunges, and delete.

administer (a)

The user can change the ACL on the mailbox.

You can combine access rights in different ways. For example:

lrs

The user can read the mailbox.

lrsp

The user can read the mailbox and can post to it through the delivery system. Most delivery systems do not provide authentication, so the `p` right usually has meaning only for the `anonymous` user.

lr

The user can see the mailbox and can read it, but the server does not preserve the `Seen` and `Recent` flags. This set of rights is useful primarily for `anonymous` IMAP.

rs

The user can read the mailbox and the server preserves the `Seen` and `Recent` flags, but the mailbox is not visible to the user through the various mailbox listing commands. The user must know the name of the mailbox to be able to access it.

lrspi

The user can read and append to the mailbox either through IMAP or through the delivery system.

Any identifier may be prefixed with a dash (-) character. The associated rights are then removed from that identifier. These are referred to as negative rights.

To calculate the set of rights granted to a user, the server first calculates the union of all rights granted to the user and to all groups of which the user is a member. The server then calculates and removes the union of all negative rights granted to the user and to all groups of which the user is a member. For example, in the following ACL, the user named Fred is granted the rights `lrswip` and the user `anonymous` is granted the rights `lrp`:

```
anyone      lrsp
fred        lwi
-anonymous  s
```

Regardless of the ACL on a mailbox, users who are listed in the `admins` configuration option of the `/etc/imapd.conf` file implicitly have the lookup and administer rights on all mailboxes. Users also implicitly have the lookup and administer rights on the `INBOX` and all of their personal mailboxes.

When a mailbox is created, its ACL starts with a copy of the ACL of its closest parent mailbox. When a user is created, the ACL on the user's `INBOX` starts with a single entry granting all rights to the user. When a nonuser mailbox is created and does not have a parent, its ACL is initialized to the value of the `defaultacl` option in the `/etc/imapd.conf` file.

13.5.9 Quotas

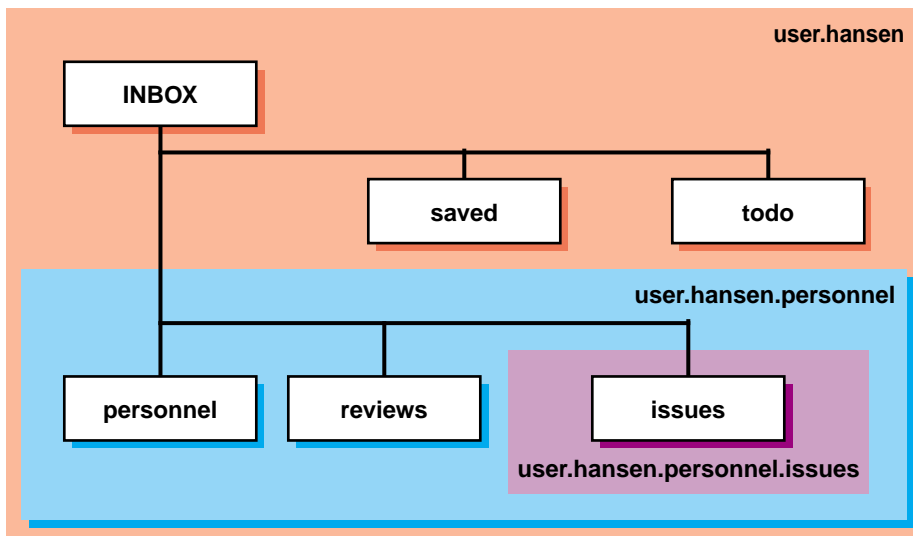

You can use quotas to limit the system resources available to a user. The IMAP server supports quotas on storage.

A quota on storage is defined as the number of kilobytes of disk space that a user's messages are permitted to consume. Each copy of a message is counted independently, even when the server can conserve disk space by making hard links to message files. The additional disk space overhead used by mailbox index and cache files is not charged against a quota.

You can assign one quota on the overall space permitted for a user's mailboxes or you can assign different quotas on selected branches of a user's mailbox hierarchy. In either case, you apply the quota to the root of the mailbox hierarchy that you want to limit. The quota root encompasses any number of mailboxes in that hierarchy. Quotas on a quota root apply to the sum of the usage by all mailboxes at that level and below that level that is not part of a quota root on lower level, hence, each mailbox is limited by at most one quota root.

Figure 13-7 shows an example of quota roots for a user named Hansen.

Figure 13-7: Quota Roots

ZK-1578U-AI

In Figure 13-7, the user Hansen has the following mail folders:

```
user.hansen (INBOX)
user.hansen.personnel
user.hansen.personnel.reviews
user.hansen.personnel.issues
user.hansen.saved
user.hansen.todo
```

The following quota roots in the `quota/h` directory restrict Hansen's disk usage:

```
user.hansen
user.hansen.personnel
user.hansen.personnel.issues
```

The quota root `user.hansen` applies to the `INBOX`, `saved`, and `todo` mail folders. The quota root `user.hansen.personnel` applies to the `personnel` and `reviews` mail folders. The quota root `user.hansen.personnel.issues` applies only to the `issues` mail folder. If the `user.hansen.personnel` and `user.hansen.personnel.issues` quota roots did not exist, the restrictions specified for the `user.hansen` root would apply to all mail folders in the `user.hansen` hierarchy (those mail folders with the `user.hansen` prefix).

You can create quota roots by using the `setquota` command in the `cyradm` utility; however, you cannot delete quota roots with this utility. To remove a quota root, you must remove the associated quota file.

For a message to be inserted into a mailbox, the mailbox must have sufficient storage so that inserting the message will not exceed the quota root. This is always true of manual transfers from one folder to another, but mail delivery is a special exception. If the limit is not exceeded when delivery starts, then the message is delivered regardless of its size. If delivery of the new message exceeds the folder's quota, the `imapd` daemon informs the user and permits him or her to correct the problem. If mail delivery were not permitted in this case, the user would not know that mail cannot be delivered.

When the quota root is exceeded, mail delivery fails with a temporary error. The system attempts delivery for a few days, providing the user time to notice and correct the problem.

When a user selects a mail folder that is near or exceeds the quota, the server issues an alert to notify the user. You can use the `quotawarn` configuration option to set the threshold of usage at which the server issues quota warnings. The server issues warnings only when the user has rights to the folder because only users with rights can correct the problem.

13.5.10 Partitions

You can use partitions to store mailboxes in different parts of your file system. Hierarchies of mailboxes can be spread across multiple disks. You must use the `cyradm` utility to specify these alternate partitions; you cannot specify them from an IMAP mail application.

When creating a new mailbox, specify the name of the partition for the mailbox as an argument to the `createmailbox` command in the `cyradm`

utility. If the partition is not specified, the mailbox inherits the partition of its parent mailbox. If the mailbox has no parent, it defaults to the partition specified in the `defaultpartition` configuration option.

You can also change the partition of an existing mailbox by using the `renamemailbox` command in the `cyradm` utility. See `cyradm(8)` for more information.

Note that quota roots are independent of partitions. A single quota root can apply to a mailbox hierarchy that spans multiple partitions.

13.6 Mail Utilities

The operating system includes the following mail utilities:

- The `mail`, `binmail` utility (the default) — Used by the `sendmail` utility to deliver mail locally. Because the `mail` utility has root `setuid` permission, it handles delivery of all mail to a user's local mailbox located in the `/var/spool/mail` directory. See the *Command and Shell User's Guide* and `mail(1)`.
- The `mailx`, `Mail` utility — A combination of the Berkeley Software Distribution's (BSD) and UNIX System Laboratories, Inc.'s System V Release 4 (SVR4) mail utilities. The `mailx` utility depends on the `binmail` utility for delivery to a user's mailbox. It has more user features than the `binmail` utility. See the *Command and Shell User's Guide* and `mail(1)`.
- The `dtmail` utility — The default mail program in CDE. This utility uses `sendmail` as the transport and stores information in much the same way as the `mailx` utility. It also allows you to read POP3 mail, and offers support for MIME-encoded messages. See the *Common Desktop Environment: User's Guide* and `dtmail(1)`.
- The message handler utility `mh` — It and its associated commands are included in the optional RAND Corporation Mail Handler subset (OSFMH). The message handler is composed of several shell commands where each command handles a specific function. For example, the `inc` command reads new mail and the `comp` command creates a message. Like the `mailx` utility, `mh` depends on the `mail` utility for delivery to a user's mailbox. The `mh` utility provides a graphical interface with the `xmh` command. It also provides the Post Office Protocol (POP). See `xmh(1X)` and Section 13.4 for more information on `xmh` and POP, respectively
- Netscape Messenger — Part of the Netscape Communicator product, which is bundled with the operating system software. Messenger allows you to read mail from POP3 and IMAP4 mail servers. It also enables you to create rich HTML Email with embedded images, send MIME-encoded attachments, encrypt and decrypt your messages for privacy, use filters

to organize your incoming messages into folders, and look up email addresses. For more information on the Netscape Communicator product, see `netscape(1)`.

For more information on `sendmail`, see `sendmail(8)`, `sendmail.cf(4)`, and `sendmail.m4(8)`.

13.7 Monitoring the Mail Queue

Monitoring the mail queue enables you to determine the status of several types of networking operations, including jobs that have been queued on a local system for transfer to a remote system. General users and system administrators can monitor the mail queue.

To display the contents of the mail queue, use the `mailq` command. This command lists the number of requests and the queue ID, the message size, the date the message entered the queue, and the sender and recipient for each request. Alternatively, you can use the `sendmail -bp` command.

See `mailq(1)` for more information.

If a major host is off line for a period of time, the number of entries in the queue might be quite large, causing the performance of the mail environment to suffer. To remedy this, you must archive the queue. See Section 13.8 for information.

The following example shows two requests in the mail queue:

```
# mailq
      Mail Queue (2 requests)
--QID-- --Size--  -----Q-Time-----  -----Sender/Recipient-----
AA04956   1442 Tue Aug 24 10:12 <blaise>
              (Deferred)
              <corcoran@host1.corp.com>
AA08618* (no control file)
```

13.8 Archiving the Mail Queue

When a major host is off line for a number of days, the mail queue might grow to be quite large. As a result, the `sendmail` utility spends a lot of time sorting the large queue, severely affecting the mail environment performance. Archiving the mail queue enables your mail environment to function normally while the major host is off line. To archive the mail queue, do the following:

1. Log in as root.
2. Change to the `/var/spool` directory by using the `cd` command.
3. Stop the `sendmail` utility by entering the following command:

```
# /sbin/init.d/sendmail stop
```

4. Verify that the `sendmail` utility is not running by entering the following command:

```
# ps -e | grep sendmail
```

5. Verify that no `sendmail` child processes are running by entering the following command:

```
# ps -e | grep queue
```

If any processes in the list are related to `sendmail`, for example, they include message queue IDs, it is best to wait until these processes are finished before moving the queue; otherwise, you might corrupt the queue data.

6. Move the `mqueue` directory to the `old.mqueue` directory by using the `mv` command.
7. Make a new `mqueue` directory by using the `mkdir` command.
8. Change the directory's permission code to `775` by using the `chmod` command.
9. Restart the `sendmail` utility by using the following command:

```
# /sbin/init.d/sendmail restart
```

After the major host returns on line, process the old mail queue by using the following command:

```
# /usr/sbin/sendmail -oQ/var/spool/old.mqueue -q
```

When the queue is empty, remove it by using the following command:

```
# rm -r /var/spool/old.mqueue
```

13.9 Administering and Distributing Alias Information

Depending on how you choose to administer and distribute alias information on standalone or server systems, there are three ways to provide alias information for use in the mail environment:

- `/var/adm/sendmail/aliases` file
- NIS aliases database
- Lightweight Directory Access Protocol (LDAP)

By default, the `/var/adm/sendmail/aliases` file permissions code is `644`. This means that global users cannot change and write the changes to the file. While this creates a reasonably secure system, it leaves the maintenance of the list of global users up to the system administrator.

You can distribute responsibility for maintenance by doing the following:

1. Create a local alias file for a global maintainer in a directory. Both the file and the directory must be accessible by another maintainer.
2. Create an entry in the `/var/adm/sendmail/aliases` file that includes the additional alias file. The entry has the following form:

```
alias_name: :include:filename
```

The *filename* is the full path name and file name of the alias file.

3. Build a new version of the alias file by using the `newaliases` command.

See `aliases(4)` for more information.

Optionally, you can use NIS to administer and distribute alias information for use in the mail environment. To use the NIS aliases database, do the following:

1. Install and configure NIS, if this is not already done, by using the `nissetup` script.
2. Edit the `svc.conf` file by using the `svcsetup` script, and modify the `aliases` entry to include `yp` (NIS).
3. Edit the NIS aliases map to include the alias information you want.

See Chapter 9 for information on configuring NIS and Section 9.4.5 for information on updating an NIS map.

Lastly, you can also use LDAP to administer and distribute alias information for use in the mail environment. LDAP might be the best choice for maintaining alias information when your alias database is too large or you have many systems in the network sharing the same information.

To use LDAP for maintaining alias information, do the following:

1. Configure LDAP server and create the proper schema for your environment. You may configure LDAP service on the mail server or, preferably, on an independent system. See `sendmail.m4(8)` and your LDAP server documentation for more information.
2. Create two attributes in your schema: one for the user's mail address and another for the user's alias.
3. Manually edit the `hostname.m4` file in the `/var/adm/sendmail` directory and make the following changes:
 - a. Set `_LDAPMap` to `{T}` to enable lookups.
 - b. Set `_LDAPParam` to define the map and its argument list. See `sendmail.m4(8)` for details.

4. Switch to the `/var/adm/sendmail` directory and execute the following command:

```
# make -f Makefile.cf.hostname
```

5. Rename the `hostname.cf` file to `sendmail.cf`, as follows:

```
# mv hostname.cf sendmail.cf
```

6. Restart the `sendmail` daemon by issuing the following command:

```
# /sbin/init.d/sendmail restart
```

Note that you need to perform steps 3–6 each time you configure mail with the `mailsetup` or the `mailconfig` utilities.

13.10 Displaying Mail Statistics

You can display statistics about mail traffic on your system by using the `mailstats` command as follows:

```
# /usr/sbin/mailstats
```

At any time, you can initialize the statistics file by issuing the following commands:

```
# cp /dev/null /var/adm/sendmail/sendmail.st
# chmod 666 /dev/null /var/adm/sendmail/sendmail.st
```

Simple Network Management Protocol

This chapter describes the Simple Network Management Protocol (SNMP) implementation on a Tru64 UNIX system.

The Simple Network Management Protocol (SNMP) is the de facto industry standard for managing Transmission Control Protocol/Internet Protocol (TCP/IP) networks. The protocol defines the role of a Network Management Station (NMS) and the SNMP Agent, allowing remote users on an NMS to monitor and manage TCP/IP network entities.

Note

Tru64 UNIX does not implement the NMS software.

Tru64 UNIX provides the `snmpd` daemon as the SNMP agent. This daemon is started at boot time. For information on how to set up and configure the `snmpd` daemon, see `snmpd(8)`.

The operating system includes two SNMP subagents:

- `os_mibs` — Implements industry-standard management information base (MIB) support, including MIB II, the FDDI MIB, the Token Ring MIB, the Host Resources MIB, and an Ethernet-like Interfaces MIB. See `os_mibs(8)` for a list of the related RFCs and Appendix G for a description of the Host Resources MIB implementation.
- `cpq_mibs` — Implements MIBs that are specific to the Tru64 UNIX operating system. See `os_mibs(8)` for more information about these MIBs.

These subagents are started and stopped automatically in conjunction with the `snmpd` daemon. Together, they provide the SNMP data required by the Insight Manager daemon, `insightd`, for managing Tru64 UNIX systems via the web. For more information, see `insightd(8)` and `insight_manager(5)`.

See the *Network Programmer's Guide* for information on registering applications with the SNMP agent.

Part 2

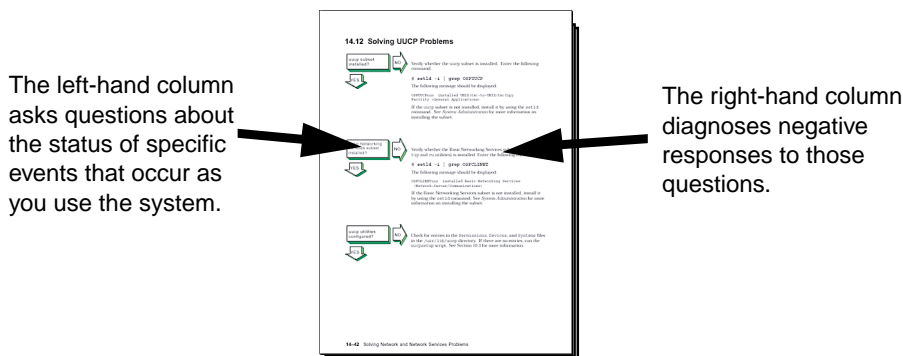

Problem Solving Information

Solving Network and Network Services Problems

This chapter contains a diagnostic map to help you solve problems that might occur when you use the network and network services software. Use this chapter together with the appropriate Compaq documentation to solve as many problems as possible at your level.

15.1 Using the Diagnostic Map

Network and network service problems can occur for a number of reasons. The diagnostic map in this chapter helps you to isolate the problem. The following figure explains how to use the diagnostic map:

After you isolate the problem, the map refers you to other chapters for instructions on using the various problem solving tools and utilities. The map also refers you to other manuals for more complete diagnostic information for particular devices and software products.

You could experience problems that are not documented in this manual when you use base system network and network services software with other layered products. See the documentation for the other products for additional information.

15.2 Getting Started

Before you start problem solving, ensure that the communications hardware is ready for use. Verify the following:

- The system's physical cable connections (the Ethernet connection and the transceiver connection) are properly installed. See the documentation for your system and communications hardware device.
- Event logging is enabled in order to monitor network events. See *System Administration* for information on starting event logging and for descriptions of the event messages.

Also see the product release notes for up-to-date information on known problems.

For solving IPv6 network problems, you must also be familiar with the following terms before you start problem solving:

on-link node

An on-link node is attached to the same subnetwork as your system. This subnetwork can be a LAN, a serial connection running PPP, or an IPv6 over IPv4 configured tunnel. There are no IPv6 routers between your system and the on-link node. For the configured tunnel, the on-link node is the node at the destination end of the tunnel.

off-link node

An off-link node is not attached to the same subnetwork as your system. There is at least one IPv6 router between your system and the off-link node.

In Figure 3–3, if your system were Host A, Host B is an on-link node, and Host C and Host D are off-link nodes.

Table 15–1 helps you identify a starting point in the diagnostic map.

Table 15–1: Problem Solving Starting Points

If your problem is:	Start here:
uucp command error	Section 15.13
Network command error	Section 15.15, if using a SLIP connection Section 15.16, if using a PPP connection Section 15.3 Section 15.4

Table 15–1: Problem Solving Starting Points (cont.)

If your problem is:	Start here:
Connecting to an ATM network	Section 15.5 Section 15.5.1, if using Classical IP Section 15.5.2, if using LANE Section 15.5.3, if using IP switching Section 15.3 Section 15.4
Obtaining an IP address using DHCP	Section 15.6 Section 15.3 Section 15.4
Correcting system time when you are using NTP	Section 15.14
Getting host name information	Section 15.8, if you are using DNS/BIND Section 15.10, if you are using NIS
Accessing files	Section 15.12, if you are using NFS Section 15.3 Section 15.4
Connecting to a host using LAT	Section 15.17
Unknown errors	Section 15.3
Unknown IPv6 errors	Section 15.4
Sending or receiving mail	Section 15.18 Section 15.19, if you are using POP or IMAP mail

15.3 Solving IPv4 Network Problems

Turn on the power to your system. See the system manual for your system's startup procedure and any problem solving information.

If you are running Network Information Service (NIS) and your system hangs after the NIS daemons are started and before it mounts remote file systems, no NIS server is available to respond to the `ybind` request. If you know there is an NIS server for your domain, wait until the server responds; the boot procedure will continue.

If there is a Local Area Transport (LAT) problem, the following message is displayed:

```
getty: cannot open "/dev/ttyxx"
```

See the solutions for solving LAT problems in Section 15.17.

If your system is a Network File System (NFS) client and it hangs while mounting a remote file system or directory, complete the following steps:

1. Inspect the cable and connection between your system and the network.
2. Wait until all the servers listed in the `/etc/fstab` file are available on the network; your system will then continue booting.
3. If you want your system to continue booting even if an NFS server is down, do the following:
 - a. Halt the system.
 - b. Boot the system to single-user mode and run the `fsck` command on the local file systems.
 - c. Edit the `/etc/fstab` file and add the `bg` (background) option to the server entries. See Chapter 10 for the correct format of an `fstab` entry with the `bg` option.
 - d. Reboot the system with the following command:

```
# /sbin/reboot
```

If the `bg` option is specified in the `fstab` file entry, the remote file system or directory is automatically mounted when the server is running and begins functioning as an NFS server.

Follow these steps to see if your network is configured:

1. If your system is new to this environment and you recently configured it for use on a network, verify that the network adapter mode is set correctly at the console level. For example, if you have a 10base2 Ethernet network and your system is configured to use 10baseT Ethernet, your system fails to see the network until you set the appropriate console variable. See the prerequisite tasks for a full installation in the *Installation Guide* for more information.
2. Use the `rcmgr` utility to display the value of the `NUM_NETCONFIG` entry in the `/etc/rc.config` file:

```
# rcmgr get NUM_NETCONFIG
```

If the value is 0, run the SysMan Menu utility to configure your network. See Section 2.3 for more information.

Verify that the network daemon (`inetd`) is running. Enter the following command:

```
# ps -e | grep inetd
```

If no `inetd` daemon is running, start it, using the following command:

```
# /sbin/init.d/inetd start
```

If a remote host's network is not reachable, the following message is displayed:

```
network is unreachable
```

Complete the following steps:

1. Ensure that the network devices are configured properly on the local host, using the `netstat -i` command. See Section 2.3 for information on configuring network devices.
2. Verify that the routing tables on the local host are correct, using the `netstat -r` command.
3. Trace the path looking at each Internet Protocol (IP) router's routing tables to find an entry for the remote host's network. Repair the incorrect IP router's routing tables. (This step requires a thorough knowledge of your topology.)
4. Verify that the local host's address-to-name translation for the remote host is correct. See the solutions for Host known?.
5. Inspect the routers along the path to the remote host to determine whether they have security features enabled that prevent you from reaching the remote host.

If a remote host is not known, the following message is displayed:

```
unknown host
```

Complete the following steps:

1. Verify that the user is trying to reach the remote host using a valid host name.
2. Verify that the remote host is in another name domain and that the user specified the full domain name.
3. If your site uses the Domain Name System (DNS) for name-to-address translation, look in the `/etc/svc.conf` file to see if `bind` is specified as a service for the `hosts` database entry. If it is not, edit the file and add it. Also, verify that the DNS service has information about the remote host. See the solutions for solving DNS/BIND client problems in Section 15.8.
4. If your site uses NIS name service for name-to-address translation, look in the `/etc/svc.conf` file to see if `yp` (NIS) is specified as a service for the `hosts` database entry. If it is not, edit the file and add it. Also, verify if the NIS service has information about the remote host. See the solutions for solving NIS client problems in Section 15.10.
5. If your `/etc/svc.conf` file lists `local` as the only name-to-address translation mechanism, the `/etc/hosts` file does not have information on the remote host. See *System Administration* for more information.

If a remote host is not reachable, the following message is displayed:

```
host is unreachable
```

Complete the following steps:

1. Inspect the cabling between the local host and the network.
2. Verify that the remote host is running, using the `ping` command.
3. Make sure that the network devices are configured properly on the local host, using the `netstat -i` command. See Section 2.3 for information on configuring network devices.
4. Verify that the routing tables on the local host are correct, using the `netstat -r` command. Use the `ping` command to determine whether the IP router is reachable.
5. Verify that the local host's address-to-name translation for the remote host is correct. See the solutions for Host known?.
6. Inspect the routers along the path to the remote host to determine whether they have security features enabled that prevent you from reaching the remote host.

If a file cannot be accessed using the `rcp` or `rsh` commands, the following message is displayed:

```
permission denied
```

Complete the following steps:

1. Verify that the user is intended to have access to the remote host. The remote host might be intentionally preventing remote access.
2. Verify that the correct host and user definitions exist in the user's `.rhosts` file on the remote host.
3. Verify that the `/etc/hosts.equiv` file is set up correctly.
4. Verify that the directory and file protection on the files to be copied or the `.rhosts` file on the remote system are correct.

If you are using NFS, go to Section 15.12.

If the connection is broken, the following message is displayed:

```
connection timed out
```

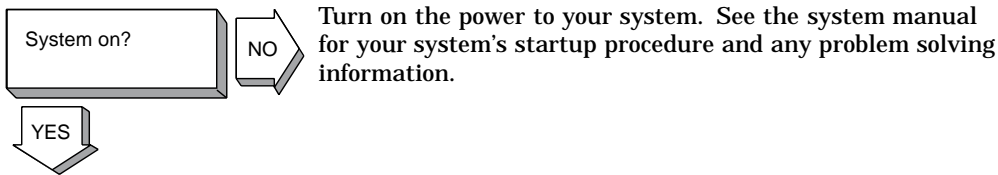

Complete the following steps:

1. Test the network to determine whether the problem is on the local host, remote host, or a host on the path between the two. See Chapter 16 for more information on testing the network.
2. After you identify the host with the problem, do the following:
 - a. Confirm that the network device is properly configured. Verify that the broadcast address and address mask for the local host are correct. See Section 2.3 for information on configuring network devices.
 - b. Make sure the local host's `/etc/hosts` file has the correct IP address for the local host.
 - c. Make sure the cabling from the local host to the network is intact and properly connected.
 - d. If connected over a local area network (LAN), verify that the Address Resolution Protocol (ARP) entries are correct and that the system is properly connected to the LAN.
 - e. If connected over a wide area network (WAN), verify that the system is properly connected to the WAN and that the modems are working properly.

Problem still exists? Report it to your service representative. See Chapter 18.

15.4 Solving IPv6 Network Problems

Turn on the power to your system. See the system manual for your system's startup procedure and any problem solving information.

If you see network-related errors or warnings during boot, complete the following steps:

1. Disable IPv6 during system boot by issuing the following command:
2. Reboot the system. If the problems persist, go to Section 15.3.
3. Start IPv6 by issuing the following command:

```
# rcmgr set IPV6 "no"
```

```
# /usr/sbin/rcinet inet6
```

If the problems reappear, look in the `/etc/rc.config`, `/etc/ip6rtrd.conf`, and `/etc/routes` files for possible errors.

Verify that the IPv6 support you want is configured in the kernel. Enter the following command:

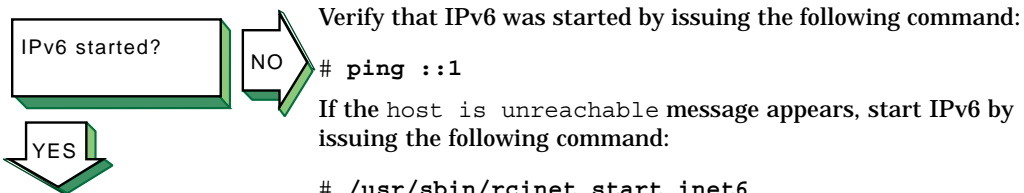

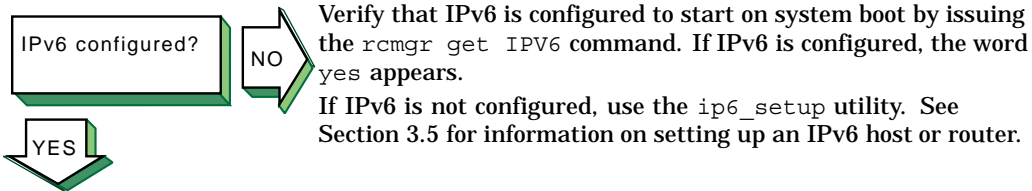

```
# sysconfig -s ipv6 | grep configured
```

If nothing is displayed, the `IPV6` option is not configured in the kernel. Reconfigure the kernel by using the `doconfig` command. See Section 3.4.1 for more information.

If you want to use configured tunnels, verify that the IP tunneling support is configured in the kernel. Enter the following command:

```
# sysconfig -s iptunnel | grep configured
```

If nothing is displayed, the `IPTUNNEL` option is not configured in the kernel. Reconfigure the kernel by using the `doconfig` command. See Section 3.4.1 for more information.

Go to Section 15.4.1 for IPv6 host problems or Section 15.4.2 for IPv6 router problems.

This creates and brings up the IPv6 interfaces, and starts the IPv6 daemons.

15.4.1 Solving IPv6 Host Problems

IPv6 daemons started?

NO

Verify that the `nd6hostd` daemon is running by issuing the following command:

```
# ps ax | grep nd6hostd
```

If the daemon is not running, verify that your system is configured as an IPv6 host by issuing the following command:

```
# rcmgr get ND6HOSTD
```

If the word `yes` is not displayed, run the `ip6_setup` utility and configure your system as an IPv6 host. Then, restart IPv6 with the following command:

```
# /usr/sbin/rcinet restart inet6
```

If the word `yes` is displayed, enable debugging for the `nd6hostd` daemon with the following command:

```
# rcmgr set ND6HOSTD_FLAGS "-d -l /usr/tmp/nd6hostd.log"
```

Then, restart IPv6.

YES

Host known?

NO

If a remote node is not known, the following message appears:

```
unknown host
```

Complete the following steps:

1. Verify that the user is using a valid node name to reach the remote node.
2. Verify that the remote node is in another name domain and that the user specified the full domain name.
3. If your site uses the DNS/BIND name service for name-to-address translation, look in the `/etc/svc.conf` file to see if `bind` is specified as a service for the `hosts` database entry. If it is not, configure your system as a DNS/BIND client. See Section 8.5.6 for more information.

Verify that your system is running IPv4. If it is not, use the local `/etc/ipnodes` file for name-to-address translations.

Also, verify that the DNS/BIND service has information about the remote node. See the solutions for solving BIND client problems in Section 15.8.

YES

4. If your site uses only NIS name service for name-to-address translation, you need to use another service for node names because NIS does not support IPv6 addresses.

Edit the `/etc/svc.conf` file and add either `bind` (DNS/BIND) or `local` (`/etc/ipnodes` file) as the service for the `hosts` database, depending on which service has the information about the remote node.

5. If your `/etc/svc.conf` file lists `local` as the only name-to-address translation mechanism, edit the `/etc/ipnodes` file and verify that the node name and address are present and accurate. Make any necessary additions or corrections.

Also, verify that there are no formatting errors in previous lines in the file. Beginning with the first entry, issue the `ping` command to each node to locate any formatting errors.

If an on-link node is not reachable, one of the following messages can appear:

```
host is unreachable
network is unreachable
timeout
```

Verify that an on-link host or router, if one exists, is reachable by using the `ping` command. If the command fails or if there are frequently dropped packets, complete the following steps:

1. If the node is attached to a LAN, look at the datalink counters by using the `netstat -I device -s` command. The counters to look at and their possible causes are as follows:
 - Zero blocks sent or received can indicate a network hardware failure or wiring problem.
 - High collision rates can indicate an improperly wired network or a node sending excessive message traffic.
 - Data overrun and buffer unavailable errors indicate your system is misconfigured.

2. Look at the IPv6 and ICMPv6 counters with the `netstat -p ipv6` and `netstat -p ipv6-icmp` commands, respectively. The counters and their possible causes:
 - Packets discarded due to error or errors generated due to ICMP errors indicate another node generating invalid messages. Other counters show more specific information.
 - Allocation errors can indicate excessive message traffic, a misconfigured system, or a program that repeatedly allocates memory without freeing it.
3. Verify that IPv6 network interfaces exist, are UP, and have `inet6` addresses by using the `ifconfig -a` command. If they do not, verify that the configuration variables in the `/etc/rc.config` file are correct. Run the `ip6_setup` utility to correct any errors.

Also, look for `nd6hostd` errors in the `/var/adm/sys-log.dated/current/daemon.log` file. See Section 16.10 for more information.

If your interface does not have a global or site-local address, contact your network administrator to verify that your local router is advertising a prefix on the link. If there is no local router, you can define a prefix by using the `ifconfig` command (see Section 3.6.5).
4. Contact the on-link system's administrator and verify that the on-link system is up and running, that it is configured for IPv6 correctly, and that the address you are using is enabled on the node's interface.
5. Issue the `ping` command to the on-link node's IPv4 address, if IPv4 is configured on both systems. If this succeeds, verify the IPv6 configuration on both systems. If the command fails, see the solutions for solving IPv4 network problems in Section 15.3.
6. Issue the `ping` command to other nodes on the link to determine whether the failure is confined to just one node or multiple nodes. Partial connectivity might indicate a faulty network device or cable on the link.
7. If the link is a configured tunnel, do the following:
 - a. Verify the tunnel source and destination addresses by using the `ifconfig -a` command. Contact the tunnel destination node's administrator and verify that your source/destination addresses match the destination/source addresses on that node.
 - b. Issue the `ping` command to the tunnel destination address. If the command fails, see the solutions for solving IPv4 network problems in Section 15.3.

If an off-link node is not reachable, one of the following messages can appear:

```
host is unreachable
network is unreachable
timeout
```

Verify that an off-link node is reachable by issuing the `ping` command. If there is 100% packet loss, complete the following steps:

1. Verify connectivity between your system and an on-link router by using the `ping` command. If the command fails or shows frequently dropped packets, follow the steps for On-link node reachable?. If you do not know the address to a router, issue the following command:

```
# ping -I interface ff02::2
```

2. Verify that the interface over which you are sending messages has a global or site-local unicast address enabled by using the `ifconfig -a` command. If it does not, contact your network administrator to verify that your local router is advertising a prefix on the link.

If the link is a configured tunnel and the router is not advertising an address prefix, manually define one for the tunnel by using the `ip6_setup` utility. See Section 3.5.1 for more information.

3. Contact the remote system's administrator to verify that the system is up and running, that it is configured for IPv6, and that the IPv6 address on its interface is the same as you are using. If the address is different, look in your system's `/etc/ipnodes` file or have the remote system administrator verify that the DNS entry is correct.
4. Verify that there is a default route (with U and G flags set) to a router on the network by issuing the `netstat -rf inet6` command. If not, contact the router administrator to verify that the router is advertising itself as a default router.

Also, look at other routers to see if your messages are getting directed on the wrong path.

5. Trace the path to the off-link node by using the `traceroute` command. See Section 16.5 and `traceroute(8)` for more information.

If there are frequently dropped packets, this might indicate network congestion or an intermittent routing problem. Do the following:

1. Verify connectivity between your system and an on-link router by using the `ping` command.
2. Trace the path to the off-link node by using the `traceroute` command. See Section 16.5 and `traceroute(8)` for more information.

If someone reports a problem reaching your node from another node, complete the following steps:

1. Verify that their node is reachable by issuing the `ping` command. If the command fails, follow the steps for On-link node reachable? or Off-link-node reachable?, depending on the location of the node.
2. If they are using a name from the DNS database, verify that the address for your node in the DNS database matches one of the addresses configured on your system's interfaces. Use the `nslookup -type=AAAA node-name` command to retrieve the address from DNS and the `ifconfig -a` command to display addresses for your system.
3. If they are using an address defined in their local `/etc/ipnodes` file, compare that address with the addresses configured on your system's interfaces. Use the `ifconfig -a` command.

If a remote node is not configured to accept a connection from your application, the following message might appear:

```
connection refused
```

Contact the remote node's system administrator and ask if the correct socket-based service definitions are defined in the `/etc/services` and `/etc/inetd.conf` files. They might be missing or commented out.

Verify that the service in the local `/etc/inetd.conf` file has either `tcp6` or `udp6` in the protocol field.

Problem still exists?
Report it to your service
representative. See
Chapter 18.

If the connection terminates abnormally or a network application appears to hang, complete the following steps:

1. Verify that there is network connectivity to the remote node by using the `ping` command immediately after the failure.

If the `ping` command fails or shows a high rate of packet loss, follow the steps for either `On-link node reachable?` or `Off-link node reachable?`, depending on the location of the remote node.

2. If your application transfers a large amount of data over the network, verify if large or fragmented messages are being handled correctly by using the `ping -s 2000 nodename` command.

If the `ping` command fails, trace the path to the remote node with 1200-byte packets by using the `traceroute nodename 1200` command. All IPv6 links must support message sizes of at least 1280 bytes. This command might show the location of the problem in the network. See Section 16.5 and `traceroute(8)` for more information.

3. Run the application with different client and server nodes located on different links in the network.

15.4.2 Solving IPv6 Router Problems

IPv6 daemons started?

NO

YES

Verify that the `ip6rtrd` daemon is running by issuing the following command:

```
# ps ax | grep ip6rtrd
```

If the daemon is not running, verify that your system is configured as an IPv6 router by issuing the following command:

```
# rcmgr get IP6RTRD
```

If the word `yes` is not displayed, run the `ip6_setup` utility and configure your system as an IPv6 router. Then, restart IPv6 with the following command:

```
# /usr/sbin/rcinet restart inet6
```

If the word `yes` is displayed, enable debugging for the `ip6rtrd` daemon with the following command:

```
# rcmgr set IP6RTRD_FLAGS "-d -l /usr/tmp/ip6rtrd.log /etc/ip6rtrd.conf"
```

Then, restart IPv6.

Host known?

NO

YES

If a remote node is not known, the following message appears:

```
unknown host
```

Complete the following steps:

1. Verify that the user is using a valid node name to reach the remote node.
2. Verify that the remote node is in another name domain and that the user specified the full domain name.
3. If your site uses the DNS/BIND name service for name-to-address translation, look in the `/etc/svc.conf` file to see if `bind` is specified as a service for the `hosts` database entry. If it is not, configure your system as a DNS/BIND client. See Section 8.5.6 for more information.

Verify that your system is running IPv4. If it is not, use the `/etc/ipnodes` file for name-to-address translation.

Also, verify that the DNS/BIND service has information about the remote node. See the solutions for solving BIND client problems in Section 15.8.

4. If your site uses only NIS name service (`yp`) for name-to-address translation, you need to use another service for node names as NIS does not support IPv6 addresses.

Edit the `/etc/svc.conf` file and add either `bind` (DNS/BIND) or `local` (`/etc/ipnodes` file) as the service for the `hosts` database, depending on which service has the information about the remote node.

Also, verify that there are no formatting errors in previous lines in the file. Beginning with the first entry, issue the `ping` command to each node to locate any formatting errors.

5. If your `/etc/svc.conf` file lists `local` as the only name-to-address translation mechanism, edit the `/etc/ipnodes` file and verify that the node name and address are present and accurate. Make any necessary additions or corrections.

If an on-link node is not reachable, one of the following messages can appear:

```
host is unreachable
network is unreachable
timeout
```

Verify that an on-link host or router, if one exists, is reachable by using the `ping` command. If the command fails or if there are frequently dropped packets, complete the following steps:

1. If the node is attached to a LAN, look at the datalink counters by using the `netstat -I device -s` command. The counters to look at and their possible causes are as follows:
 - Zero blocks sent or received can indicate a network hardware failure or wiring problem.
 - High collision rates can indicate an improperly wired network or a node sending excessive message traffic.
 - Data overrun and buffer unavailable errors indicate your system is misconfigured.

2. Look at the IPv6 and ICMPv6 counters with the `netstat -p ipv6` and `netstat -p ipv6-icmp` commands, respectively. The counters to look at and their possible causes are as follows:
 - Packets discarded due to error or errors generated due to ICMP errors indicate another node generating invalid messages. Other counters show more specific information.
 - Allocation errors can indicate excessive message traffic, a misconfigured system, or a program that repeatedly allocates memory without freeing it.
3. Verify that IPv6 network interfaces exist, are UP, and have inet6 addresses by using the `ifconfig -a` command. If they do not, verify that the `/etc/rc.config` and `/etc/ip6rtrd.conf` files are correct.

Also, look for `ip6rtrd` errors in the `/var/adm/syslog.dated/current/daemon.log` file. See Section 16.10 for more information.

Run the `ip6_setup` utility to correct any errors.
4. Contact the on-link system's administrator and verify that the on-link system is up and running, that it is configured for IPv6 correctly, and that the address you are using is enabled on the node's interface.
5. Issue the `ping` command to the on-link node's IPv4 address, if IPv4 is configured on both systems. If this succeeds, verify the IPv6 configuration on both systems. If the command fails, see the solutions for solving IPv4 network problems in Section 15.3.
6. Issue the `ping` command to other nodes on the link to determine whether the failure is confined to just one node or multiple nodes. Partial connectivity might indicate a faulty network device or cable on the link.
7. If the link is a configured tunnel, do the following:
 - a. Verify the tunnel source and destination addresses by using the `ifconfig -a` command. Contact the tunnel destination node's administrator and verify that your source/destination addresses match the destination/source addresses on that node.
 - b. Issue the `ping` command to the tunnel destination address. If the command fails, see the solutions for solving IPv4 network problems in Section 15.3.

If an off-link node is not reachable, one of the following messages can appear:

host is unreachable
network is unreachable
timeout

Verify that an off-link node is reachable by issuing the `ping` command. If there is 100% packet loss, complete the following steps:

1. Verify connectivity between your system and the next router in the path to the off-link node by using the `ping` command. If the command fails or shows frequently dropped packets, follow the steps for On-link node reachable?.
2. Verify that the interface over which you are sending messages has a global or site-local unicast address enabled by using the `ifconfig -a` command. If it does not, verify that the interface address prefixes defined in the `/etc/ip6rtrd.conf` file (see `ip6rtrd.conf(4)`) are correct. Run the `ip6_setup` utility to correct any prefix errors.
3. Contact the remote system's administrator to verify that the system is up and running, that it is configured for IPv6, and that the IPv6 address on its interface is the same as the address that you are using. If the address is different, look in the hosts database.

4. Verify that there is a specific route to the next router in the path to the remote node by issuing the `netstat -rf inet6` command. If the route is missing or incorrect, verify that the routes in `/etc/routes` and the address prefixes in `/etc/ip6rtrd.conf` are correct.

If your site uses RIPng, verify that RIP is enabled in the `/etc/ip6rtrd.conf` file. If it is, contact the administrator of the next router to verify that RIP is enabled.

5. Trace the path to the off-link node by using the `traceroute` command. See Section 16.5 and `traceroute(8)` for more information.

If there are frequently dropped packets, this might indicate network congestion or an intermittent routing problem. Do the following:

1. Verify connectivity between your system and an on-link router by using the `ping` command.
2. Trace the path to the off-link node by using the `traceroute` command. See Section 16.5 and `traceroute(8)` for more information.

IPv6 hosts generate their global and site-local unicast addresses automatically using address prefixes provided by a router on the link. If an on-link node cannot autoconfigure its addresses, complete the following steps:

1. Verify that the host is reachable from your router by using the `ping` command and specifying the host's link-local address. If the command fails or shows a high rate of packet loss, follow the steps for On-link node reachable?.
2. Edit the `/etc/ip6rtrd.conf` file and verify that the router is configured to advertise the correct prefixes and that the timers are reasonable. See Section 3.6.11 and `ip6rtrd.conf(4)` for more information.

If another network user reports that message transmission appears to be failing at your router, complete the following steps:

1. Obtain the source and destination addresses of the message that your router is not forwarding. Then, verify that your router can reach each node by using the `ping` command. If either command fails or shows a high rate of packet loss, follow the steps for `On-link node reachable?` or `Off-link node reachable?`, as applicable.
2. If your router is running the RIPng protocol, verify that the IPv6 router daemon is running by issuing the following command:

```
# ps ax | grep ip6rtrd
```

If it is running, edit the `/etc/ip6rtrd.conf` file and verify that the RIPng protocol is enabled on each IPv6 link. If it is not, your node may not be propagating routes correctly.

3. Make sure that you are not using manual routes on some interfaces and RIPng routes on other interfaces. Manual routes defined in the `/etc/routes` file do not get propagated to other routers with RIPng.

If someone reports a problem reaching your node from another node, complete the following steps:

1. Verify that their node is reachable by issuing the `ping` command. If the command fails, follow the steps for `On-link node reachable?` or `Off-link-node reachable?`, depending on the location of the node.
2. If they are using a name from the DNS database, verify that the address for your node in the DNS database matches one of the addresses configured on your system's interfaces. Use the `nslookup -type=AAAA node-name` command to retrieve the address from DNS and the `ifconfig -a` command to display addresses for your system.
3. If they are using an address defined in their local `/etc/ipnodes` file, compare that address with the addresses configured on your system's interfaces. Use the `ifconfig -a` command.

If a remote node is not configured to accept a connection from your application, the following message might appear:

`connection refused`

Contact the remote node's system administrator and ask if the correct socket-based service definitions are defined in the `/etc/services` and `/etc/inetd.conf` files. They might be missing or commented out.

Verify that the service in the local `/etc/inetd.conf` file has either `tcp6` or `udp6` in the protocol field.

If the connection terminates abnormally or a network application appears to hang, complete the following steps:

1. Verify that there is network connectivity to the remote node by using the `ping` command immediately after the failure.

If the `ping` command fails or shows a high rate of packet loss, follow the steps for either `On-link node reachable?` or `Off-link node reachable?`, depending on the location of the remote node.

2. If your application transfers a large amount of data over the network, verify if large or fragmented messages are being handled correctly by using the `ping -s 2000 nodename` command.

If the `ping` command fails, trace the path to the remote node with 1200-byte packets by using the `traceroute nodename 1200` command. All IPv6 links must support message sizes of at least 1280 bytes. This command might show the location of the problem in the network. See Section 16.5 and `traceroute(8)` for more information.

3. Run the application with different client and server nodes located on different links in the network.

Problem still exists?
Report it to your service representative. See Chapter 18.

15.5 Solving ATM Problems

Verify that the ATM subsets are installed. Enter the following command:

```
# setld -i | grep OSFATM
```

The following messages is displayed:

```
OSFATMnnn installed ATM Commands  
  (Network-Server/Communications)  
OSFATMBINnnn installed ATM Kernel  
  Modules (Kernel Build Environment)  
OSFATMBINCOMnnn installed ATM Kernel  
  Header and Common Files  
  (Kernel Build Environment)  
OSFATMBINOBJECTnnn installed ATM Kernel  
  Objects (Kernel Software Environment)
```

If the OSFATM, OSFATMBIN, and OSFATMBINCOM subsets are not installed, install them by using the `setld` command. See *System Administration* for information on installing the subset.

Verify that the ATM support you want is configured in the kernel. Enter the following command:

```
# sysconfig -q atm
```

If nothing is displayed, ATM is not configured in the kernel. Reconfigure the kernel with the ATM option and additional ATM options as needed. See Section 4.2.2 for a list of ATM kernel options and for information on reconfiguring the kernel.

If ATM is configured in the kernel, use the `sysconfig -q` command to verify that other ATM kernel options are configured. Reconfigure the kernel with additional options as needed.

Go to Section 15.5.1 for Classical IP, go to Section 15.5.2 for LAN Emulation, or go to Section 15.5.3 for IP switching.

Verify that the driver is configured by using the `atmconfig drvlist` command. If the driver is configured, information similar to the following is displayed:

```
Name: lta0      Type: STS-3      State: UP
Driver ID: 1   ESIs: 8     PPAs: 9   VCs: 6
```

If an entry for the driver does not exist, use the `genvmunix` kernel to reboot the system and run the `doconfig` utility to build a kernel with the required driver.

If the driver state is not UP, run the `atmsetup` utility for the ATM service you want. See Section 4.3.2.4, Section 4.3.3.3, and Section 4.3.4.2 for information on configuring the driver for Classical IP (CLIP), LAN emulation (LANE), and IP switching, respectively.

15.5.1 Solving CLIP Problems

Signaling configured?
(SVCs only)

NO

YES

Verify that signaling is configured. Enter the following command:

```
# atmsig status driver=driver_name
```

If the UNI version number is not displayed or the ILMI state is Unknown, run the `atmsetup` utility and configure signaling. See Section 4.3.2.4 for information.

lis interfaces created?

NO

YES

Verify that the CLIP `lis` interfaces are created. Enter the following command:

```
# atmarp -h
```

If a `lis` interface is created, the status of all created LISs and data indicating whether the host is an ARP client or ARP server is displayed.

If no LISs are created, run the `atmsetup` utility and configure CLIP. See Section 4.3.2.4 for more information.

lis interfaces configured?

NO

YES

Verify that a `lis` interface is configured. Enter the following command:

```
# ifconfig lisx
```

If a `lis` interface is configured, information similar to the following is displayed:

```
lis0: flags=c23<UP,BROADCAST,NOTRAILERS,MULTICAST,SIMPLEX>
      inet 10.140.120.52 netmask ffffffff broadcast 10.140.120.255
      ipmtu 1500
```

If a `lis` interface is not configured, run the `netconfig` utility to configure one or use the Interfaces application from the SysMan Menu. See Section 4.3.2.5 for more information.

If a remote host is not known, the following message is displayed:

```
unknown host
```

Complete the following steps:

1. Verify that the user is using a valid host name to reach the remote host.
2. Verify that the remote host is in another name domain and that the user specified the full domain name.
3. If your site uses DNS for name-to-address translation, look in the `/etc/svc.conf` file to see if `bind` is specified as a service for the `hosts` database entry. If it is not, edit the file and add it.

Also, verify that DNS has information about the remote host. See Section 15.8.

4. If your site uses NIS name service for name-to-address translation, look in the `/etc/svc.conf` file to see if `nis` is specified as a service for the `hosts` database entry. If it is not, edit the file and add it.

Also, verify that the NIS service has information about the remote host. See Section 15.10.

5. If your `/etc/svc.conf` file lists `local` as the only name-to-address translation mechanism, the `/etc/hosts` file does not have information on the remote host. See *System Administration* for more information.

If a remote host is not reachable, the following message is displayed:

```
host is unreachable
```

Complete the following steps:

1. Verify that the cabling between the local host and the switch is properly installed and undamaged.
2. Verify that there is network connectivity to the IP controller on the switch by using the `ping` command. If the command fails, it might be because the `ifconfig` command parameters are wrong, or the IP controller is down or has an interface problem. Contact the switch administrator.
3. Verify that there is network connectivity to the target remote host by using the `ping` command. If the command fails, use the `traceroute` command to verify the route to the remote host.

Problem still exists?
Report it to your service
representative. See
Chapter 18.

If the connection terminates abnormally, complete the following steps:

1. Test the network to determine whether the problem is on the local host, remote host, or a host on the path between the two. See Section 15.3.
2. Once you have identified the host with the problem, do the following:
 - a. Confirm that the network device is properly configured. Verify that the broadcast address and address mask for the local host are correct. See Section 2.3 for information on configuring network devices.
 - b. Make sure the local host's `hosts` database has the correct IP addresses.
 - c. Make sure the cabling from the local host to the network is intact and properly connected.
 - d. If connected over a LAN, verify that the ARP entries are correct and that the system is properly connected to the LAN.

15.5.2 Solving LANE Problems

Verify that signaling is configured. Enter the following command:

```
# atmsig status driver=driver_name
```

If no User-Network Interface (UNI) version number is displayed or the Integrated Layer Management Interface (ILMI) state is `Unknown`, run the `atmsetup` utility and configure signaling. See Section 4.3.3.3 for information.

Verify that an `elan` interface is created. Enter the following command:

```
# atmelan show
```

If an `elan` interface is created, information similar to the following is displayed:

```
:\ncontrol state: S_OPERATIONAL\n:\n:
```

If the control state is not `S_OPERATIONAL`, do the following:

1. Increase the message logging level for the `lane` subsystem. See Section 4.4.6 for more information.
2. Verify that the UNI version on the switch matches the UNI version on your system.
3. Verify that the LAN Emulation Server (LES) on the switch is configured correctly.

Verify that an `elan` interface is configured. Enter the following command:

```
# ifconfig elanx
```

If an `elan` interface is configured, information similar to the following is displayed:

```
elan0: flags=c23<UP,BROADCAST,NOTRAILERS,MULTICAST,SIMPLEX>\n      inet 10.140.120.52 netmask ffffffff broadcast 10.140.120.255\n      ipmtu 1500
```

If an `elan` interface is not configured, run the `netconfig` utility to configure one or use the `Interfaces` application from the SysMan Menu. See Section 4.3.3.4 for more information.

If a remote host is not known, the following message is displayed:

```
unknown host
```

Complete the following steps:

1. Verify that the user is using a valid host name to reach the remote host.
2. Verify that the remote host is in another name domain and that the user specified the full domain name.
3. If your site uses DNS for name-to-address translation, look in the `/etc/svc.conf` file to see if `bind` is specified as a service for the `hosts` database entry. If it is not, edit the file and add it.

Also, verify that DNS has information about the remote host. See Section 15.8.

4. If your site uses NIS name service for name-to-address translation, look in the `/etc/svc.conf` file to see if `nis` is specified as a service for the `hosts` database entry. If it is not, edit the file and add it.

Also, verify that the NIS service has information about the remote host. See Section 15.10.

5. If your `/etc/svc.conf` file lists `local` as the only name-to-address translation mechanism, the `/etc/hosts` file does not have information on the remote host. See *System Administration* for more information.

If a remote host is not reachable, the following message is displayed:

```
host is unreachable
```

Complete the following steps:

1. Verify that the cabling between the local host and the switch is properly installed and undamaged.
2. Verify that the addresses on the link are correct by using the `ifconfig elanx` command.
3. Verify that there is network connectivity to the target remote host by using the `ping` command. If the command fails, use the `traceroute` command to verify the route to the remote host.

Problem still exists?
Report it to your service
representative. See
Chapter 18.

If the connection terminates abnormally, complete the following steps:

1. Test the network to determine whether the problem is on the local host, remote host, or a host on the path between the two. See Section 15.3.
2. Once you have identified the host with the problem, do the following:
 - a. Confirm that the network device is properly configured. Verify that the broadcast address and address mask for the local host are correct. See Section 2.3 for information on configuring network devices.
 - b. Make sure the local host's `hosts` database has the correct IP addresses.
 - c. Make sure the cabling from the local host to the network is intact and properly connected.
 - d. If connected over a LAN, verify that the ARP entries are correct and that the system is properly connected to the LAN.

15.5.3 Solving IP Switching Problems

Verify that an IP switching `ips` interface is created. Enter the following command:

```
# atmifmp showips
```

If an `ips` interface is created, information similar to the following is displayed for each created `ips` interface:

```
ips0:
  Attached to driver lta0
  Default (SNAP) VC = 32
  IP Traffic VC = 1850 (Unused - peer does
    not support Flow Type 0)
  Min Tx VC = 1
  Max Tx VC = 2048
  Min Rx VC = 1
  Max Rx VC = 2048
  Driver Min Tx VC = 1
  Driver Max Tx VC = 2048
  Driver Min Rx VC = 1
  Driver Max Rx VC = 2048
  Peer does not support Flow Type 0
```

This example shows that the `ips0` interface was created and is attached to driver `lta0`.

If no `ips` interfaces are found, create one or more `ips` interfaces. See Section 4.3.4 for more information.

Verify that an `ips` interface is configured. Enter the following command:

```
# ifconfig ipsx
```

If an `ips` interface is configured, information similar to the following is displayed:

```
ips0: flags=4d1<UP,POINTOPOINT,RUNNING,NOARP,MULTICAST>
  inet 16.142.128.129 --> 16.142.128.130 netmask ffffffff ipmtu 1500
```

The example shows that the interface is up and running and that addresses are configured for each end of the point-to-point link.

If an `ips` interface is not configured, run the `netconfig` utility to configure one or use the Interfaces application from the SysMan Menu. See Section 4.3.4.3 for more information.

If a remote host is not known, the following message is displayed:

```
unknown host
```

Complete the following steps:

1. Verify that the user is using a valid host name to reach the remote host.
2. Verify that the remote host is in another name domain and that the user specified the full domain name.
3. If your site uses the DNS for name-to-address translation, look in the `/etc/svc.conf` file to see if `bind` is specified as a service for the `hosts` database entry. If it is not, edit the file and add it.

Also, verify that DNS has information about the remote host. See Section 15.8.

4. If your site uses NIS name service for name-to-address translation, look in the `/etc/svc.conf` file to see if `nis` is specified as a service for the `hosts` database entry. If it is not, edit the file and add it.

Also, verify that the NIS service has information about the remote host. See Section 15.10.

5. If your `/etc/svc.conf` file lists `local` as the only name-to-address translation mechanism, the `/etc/hosts` file does not have information on the remote host. See *System Administration* for more information.

If a remote host is not reachable, the following message is displayed:

```
host is unreachable
```

Complete the following steps:

1. Verify that the addresses on the point-to-point link to the switch are correct by using the `ifconfig ipsx` command.
2. Verify the connection to the IP controller on the switch by using the `ping` command. If the command fails, the local host's `ifconfig` command parameters might be incorrect. On the switch, the problem might be that the IP controller is down or has an interface problem. Contact the switch administrator.
3. Verify that there is an `ips` route to the remote host's subnet by using the `netstat -r` command.

If the ping command fails, complete the following steps:

1. Verify that the cabling between the local host and the switch is properly installed and undamaged.
2. Verify that the default Subnetwork Attachment Point (SNAP) virtual circuit (VC) specified on the local host matches the default SNAP VC on the switch.
3. Contact the remote system administrator and verify that the remote system is up and running and that it is configured correctly for IP switching.
4. Verify the route to the remote host by using the `tracert` command. If the first hop in the output shows the default network interface and not the IP controller, add a static route to the remote subnet through the IP controller to your routing table. Use the `netstat -r` command to verify the change.

If the route reaches the IP controller but goes no further, contact the remote system's administrator to verify that the system is configured correctly and that the routing tables are correct.

If the connection terminates abnormally, complete the following steps:

1. Test the network to determine whether the problem is on the local host, remote host, or a host on the path between the two. See Section 15.3.
2. Once you have identified the host with the problem, do the following:
 - a. Confirm that the network device is properly configured. Verify that the broadcast address and address mask for the local host are correct. See Section 2.3 for information on configuring network devices.
 - b. Make sure the `hosts` database on the local host has the correct IP addresses.
 - c. Make sure the cabling from the local host to the network is intact and properly connected.

Problem still exists?
Report it to your service representative. See Chapter 18.

15.6 Solving DHCP Problems

Additional Networking Services subset installed?

NO

YES

Verify that the Additional Networking Services subset is installed. Enter the following command:

```
# setld -i | grep OSFINET
```

If the subset is installed, the following message is displayed:

```
OSFINETnm installed Additional Networking Services
(Network-Server/Communications)
```

If the subset is not installed, install it by using the `setld` command. See *System Administration* for more information on installing the subset.

DHCP configured?

NO

YES

Complete the following steps to verify that Dynamic Host Configuration Protocol (DHCP) has been configured on both server and client:

1. Use the `rcmgr` utility to display the value of the `JOIND` entry in the `/etc/rc.config.common` file on the DHCP server:

```
# rcmgr get JOIND
```

If nothing is returned, run the SysMan Menu utility to configure your DHCP server. See Section 5.4 for more information.
2. Use the `rcmgr` utility to display the value of the `IFCONFIG_n` entry in the `/etc/rc.config` file on the DHCP client. For example:

```
# rcmgr get IFCONFIG_0
```

A value similar to the following is displayed:

```
DYNAMIC netmask n.n.n.n
```

If a similar value is not returned, run the SysMan Menu utility to configure your DHCP client. See Section 2.3 for more information.

DHCP server reachable?

NO

YES

Verify that the DHCP server is running and reachable, using the `ping` command.

DHCP daemon started?

Verify that the DHCP daemon (`joind`) is running on the server. Enter the following command:

```
# ps -e | grep joind
```

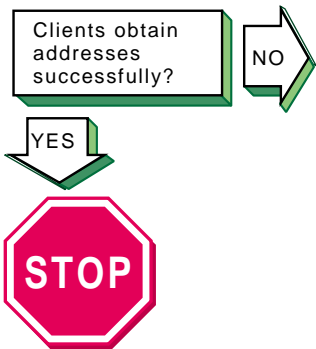

Alternatively, you can use the SysMan Menu utility to view the status of the DHCP daemon. You can skip directly to the status dialog box by entering the following command:

```
# /usr/sbin/sysman dmnstatus
```

If the DHCP daemon is not running, start it by entering the following command:

```
# /usr/sbin/joind
```

Problem still exists? Report it to your service representative. See Chapter 18.

If a DHCP client has problems obtaining DHCP information from the server, do the following:

1. Verify the Media Access Control (MAC) address you entered for the client. Users of Microsoft clients specifically must see Section 5.3.5, which explains how these clients modify their MAC addresses before sending them to the DHCP server.
2. Run the `joind` daemon with the debugging flag by doing the following:
 - a. Stop the `joind` daemon with the `kill -HUP` command.

Caution

Never use the `kill -9` command to stop the DHCP server daemon; it can corrupt your database files.

- b. Restart the `joind` daemon with the debug flag as follows:

```
# /usr/sbin/joind -d4
```

If you are running `joind` from the `/etc/inetd.conf` file, do the following:

- i. Edit the `/etc/inetd.conf` file and add the `-d4` flag.
- ii. Stop the `joind` daemon with the `kill -HUP` command.
- iii. Stop the `inetd` daemon with the `inetd -h` command. This forces the `inetd` daemon to reread the `/etc/inetd.conf` file.

Alternatively, you can run the SysMan Menu utility to configure your DHCP server with the debug option. See Section 5.4 for more information.

3. Review the `/var/join/log` file for information about the cause of any DHCP client problems.

The following example shows a `/var/join/log` file message that indicates a DHCP discover message arrived at the server system, but the IP subnetwork address range is not defined:

```
DHCPDISCOVER from HW address 08:00:2b:96:79:b6 :
network not administered by server
```

This problem can also occur if an address range is defined, but the `/etc/join/netmasks` file is missing the subnetwork mask definition for this IP network. In this case, edit the `netmasks` file, add an entry for the subnetwork, and restart the DHCP server, `/usr/sbin/joind`.

15.7 Solving DNS/BIND Server Problems

Verify that the Additional Networking Services subset is installed. Enter the following command:

```
# setld -i | grep OSFINET
```

If the subset is installed, the following message is displayed:

```
OSFINETnnn installed Additional Networking Services  
(Network-Server/Communications)
```

If the subset is not installed, install it by using the `setld` command. See *System Administration* for more information on installing the subset.

Use the `rcmgr` utility to display the value of the `BIND_SERVERTYPE` entry in the `/etc/rc.config.common` file:

```
# rcmgr get BIND_SERVERTYPE
```

If no type is specified, run the SysMan Menu utility to configure your DNS server. See Section 8.5 for more information.

Verify that the BIND daemon (`named`) is running. Enter the following command:

```
# ps -e | grep named
```

If no `named` process is running, start the `named` daemon, using the following command:

```
# /sbin/init.d/named start
```

If you have enabled authentication, and secure dynamic updates or secure zone transfers are not successful, look for errors in the `daemon.log` file generated by the `syslogd` daemon. For secure dynamic updates, examine the log on the master server. For secure zone transfers, examine the log on the master server and the slave server. See Section 16.10 for more information about viewing `syslogd` message files.

If you see a syntax error near `'item'` message, look for syntax errors in your `named.conf` file and key file (possibly `named.keys`). Verify that there are no missing braces, quotes, or semicolons. If necessary, compare the contents of these files with those in Section 8.6.3. If you see an unknown key `'key-name'` message or an Invalid TSIG secret `"key-string"` message, do the following:

1. Verify that you are using the correct key for the update or transfer.
2. Verify the spelling of the key name.
3. Verify the integrity of the key string. There must be no line feeds or spaces between the quotes that contain the key.
4. Verify that the algorithm specified for the key is `hmac-md5` and that the key was generated correctly. If necessary, generate a new key. See Section 8.6 for more information.

If the `nslookup` command does not return information for any host or the host specified in the client `nslookup` command, use the value of the `BIND_SERVERTYPE` entry you collected in a previous step to select a course of action from the table:

If the type is:	Go to:
CLIENT	Stop. This system is not a DNS/BIND server and cannot provide name resolution to clients.
MASTER	Section 17.4
SLAVE	Section 17.4
FORWARDER	Section 17.5
CACHING	Section 17.9

Problem still exists? Report it to your service representative. See Chapter 18.

15.8 Solving DNS/BIND Client Problems

Verify that the Additional Networking subset is installed. Enter the following command:

```
# setld -i | grep OSFINET
```

If the subset is installed, the following message is displayed:

```
OSFINETnnn installed Additional Networking Services  
(Network-Server/Communications)
```

If the subset is not installed, install it by using the `setld` command. See *System Administration* for more information on installing the subset.

Use the `rcmgr` utility to display the value of the `BIND_SERVERTYPE` entry in the `/etc/rc.config.common` file:

```
# rcmgr get BIND_SERVERTYPE
```

If no type is specified, run the SysMan Menu utility to configure your DNS client. See Section 8.5 for more information.

If you attempt to use one of the network commands (for example, `telnet`, `rlogin`, and `rsh` commands) and the remote host is not known, the following message is displayed:

```
unknown host
```

Complete the following steps:

1. Look in the `/etc/svc.conf` file to determine if DNS is being used for the `hosts` database lookup. If it is, go to step 2. If it is not, add it to the file by using the `/usr/sbin/svcsetup` script.
2. Retrieve information about the remote host with which you tried to communicate by using the `nslookup` command. Enter the following command:

```
# nslookup hostname
```

If the command succeeds, the client is set up correctly; try the network command again. If the command fails, go to step 3.
3. View the `/etc/resolv.conf` file and retrieve the addresses for the `nameserver` entries.
4. Verify that the servers are reachable by using the `ping` command. If no servers are reachable, contact your network administrator. If any name server fails to respond to the `ping` command, delete the name server entry from the `resolv.conf` file.
5. Try the `nslookup` command again. If the command fails, see the solutions for solving DNS/BIND server problems in Section 15.7.

Problem still exists? Report it to your service representative. See Chapter 18.

15.9 Solving NIS Server Problems

Verify that the Additional Networking Services subset is installed. Enter the following command:

```
# setld -i | grep OSFINET
```

If the subset is installed, the following message is displayed:

```
OSFINETnnn installed Additional  
Networking Services  
(Network-Server/Communications)
```

If the subset is not installed, install it by using the `setld` command. See *System Administration* for more information on installing the subset.

Use the `rcmgr` utility to display the value of the `NIS_CONF` entry in the `/etc/rc.config.common` file:

```
# rcmgr get NIS_CONF
```

If nothing is returned, run the SysMan Menu utility to configure your NIS server. See Section 9.3 for more information.

Verify that the `portmap` daemon is running. Enter the following command:

```
# ps -e | grep portmap
```

If you do not find the `portmap` daemon, stop and restart NIS, using the following commands:

```
# /sbin/init.d/nis stop  
# /sbin/init.d/nis start
```

If the `portmap` daemon does not start, reboot the server.

Verify that a `ypserv` process is running. Enter the following command:

```
# ps -e | grep yp
```

If no `ypserv` process is running, stop and start NIS, using the following commands:

```
# /sbin/init.d/nis stop  
# /sbin/init.d/nis start
```

If a `ypserv` process is running, execute a `ypwhich` command. Enter the following command:

```
# ypwhich
```

If nothing is returned, find the process ID (PID) of the `portmap` process and kill it. Enter the following commands:

```
# ps -e | grep portmap  
# kill -9 portmap_PID
```

Note

Because other network services use the `portmap` daemon, stopping it can affect network service. Therefore, notify your users of potential disruptions.

Stop and start NIS by using the following commands:

```
# /sbin/init.d/nis stop  
# /sbin/init.d/nis start
```

Verify that the information in the map is correct. Enter the following command:

```
# ypcat map_name
```

The *map_name* variable is the name of the NIS map. If the information is incorrect, create a new map. Enter the following commands:

```
# cd /var/yp  
# make map_name
```

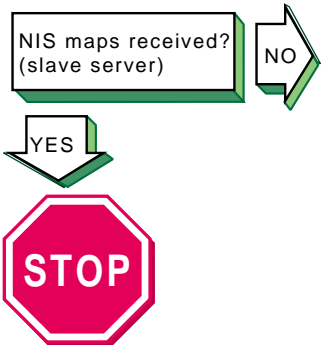

The following message is displayed:

```
map_name updated
```

If the `make` command indicates that the database is not updated, complete the following steps:

1. Remove the *database_name.time* file in the `/var/yp` and `/var/yp/domainname` directories.
2. Create a new map by using the `make` command. Enter the following commands:

```
# cd /var/yp  
# make map_name
```

Problem still exists? Report it to your service representative. See Chapter 18.

If you suspect that a slave server is not getting NIS map updates, complete the following steps on the slave server:

1. Verify that the NIS master server is running and reachable, using the `ping` command. See Section 16.2 for more information on using the `ping` command.
2. Create a `ypxfr` log file. Enter the following commands:

```
# cd /var/yp
# touch ypxfr.log
```
3. Run `ypxfr` interactively to get map updates. Enter the following command:

```
# ypxfr mapname
```
4. Examine the `ypxfr.log` file and resolve any problems. Remove the log file to turn logging off.
5. Verify the `ypxfr` entries in the `/var/spool/cron/crontabs/root` file. Use either the `pg` command or the `/usr/bin/crontab -l` command. The slave server entries are similar to the following:

```
# Network Information Service: SLAVE server entries
30 * * * * sh /var/yp/ypxfr_1perhour
31 1,13 * * * sh /var/yp/ypxfr_2perday
32 1 * * * sh /var/yp/ypxfr_2perday
```
6. Verify that the map has an entry in the corresponding `ypxfr` shell script.
7. Look in the `syslogd` daemon message files for any NIS messages. See Section 16.10 for more information.
8. Verify that the slave server is in the `ypservers` map for the domain.

15.10 Solving NIS Client Problems

NIS configured?

NO

YES

Use the `rcmgr` utility to display the value of the `NIS_CONF` entry in the `/etc/rc.config.common` file:

```
# rcmgr get NIS_CONF
```

If nothing is returned, run the SysMan Menu utility to configure your NIS client. See Section 9.3 for more information.

NIS entries in svc.conf file?

NO

YES

Use the `/usr/sbin/svcsetup` script to verify that the `svc.conf` file contains entries for NIS. NIS entries are indicated by the letters “yp.” For the `passwd` and `group` databases, the Security Integration Architecture (SIA) controls whether or not NIS is used. However, in order to use NIS, a plus sign followed by a colon (+:) must be on the last line in both databases.

portmap daemon started?

NO

YES

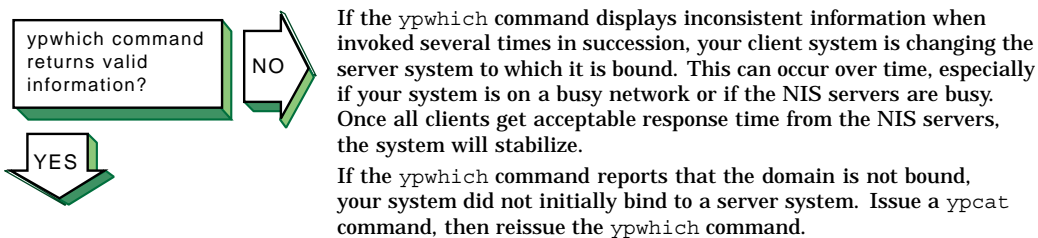

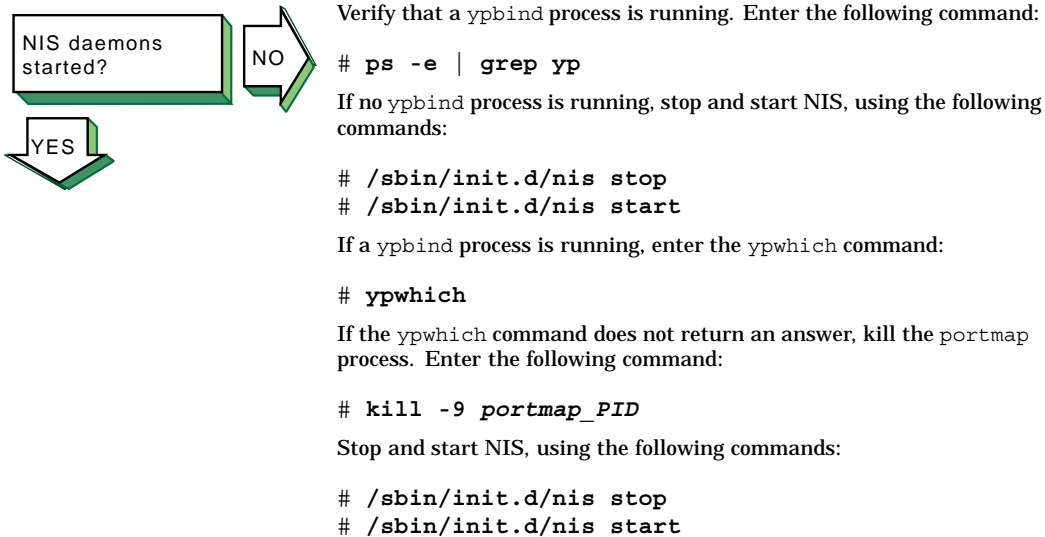

Verify that the `portmap` daemon is running. Enter the following command:

```
# ps -e | grep portmap
```

If no `portmap` daemon is running, stop and restart NIS, using the following commands:

```
# /sbin/init.d/nis stop
# /sbin/init.d/nis start
```

If the `portmap` daemon does not start, reboot the client.

If an NIS command hangs, the following message is displayed on the console:

```
yp: server not responding for domain domainname.  
Still trying
```

The client cannot communicate with the server. Complete the following steps:

Problem still exists? Report it to your service representative. See Chapter 18.

1. Use the `rcmgr` command to verify that the domain name returned by the `domainname` command matches the value of the `NIS_DOMAIN` entry in the server's `/etc/rc.config.common` file:

```
# rcmgr get NIS_CONF
```

If the domain name does not match, or is not correct for your environment (note that the domain name is case-sensitive), reconfigure the client system by using the SysMan Menu utility. See Section 9.3 for more information.

2. Verify that at least one NIS server for your domain is running on your local subnetwork. If there is not, reconfigure the client by using the SysMan Menu utility, and choose to use the `-s` option to the `ypbind` command.
3. Determine if other clients on the subnetwork are having problems with any of the NIS commands.
4. Verify that `ypserv` daemon was started on the server by entering the following command:

```
# rpcinfo -p server_name
```

Also, verify that the `ypserv` daemon is currently running on the server by entering the following command:

```
# rpcinfo -t server_name ypserv 2
```

If the server fails either test, stop and restart NIS on the server as follows:

```
# /sbin/init.d/nis stop  
# /sbin/init.d/nis start
```

5. Look in the `syslogd` daemon message files for any NIS messages. See Section 16.10 for more information.
6. Verify that the server is running. See the solutions for solving NIS server problems in Section 15.9.

If the previous steps do not solve the problem, complete the following steps:

1. Stop and start NIS. Enter the following commands:

```
# /sbin/init.d/nis stop  
# /sbin/init.d/nis start
```

If this does not solve the problem, go to step 2.

2. Reboot the system.
3. Reconfigure NIS by running the SysMan Menu utility.

15.11 Solving NFS Server Problems

NFS subset installed?

NO

YES

Verify that the NFS subset is installed. Enter the following command:

```
# setld -i | grep OSFNFS
```

If the subset is installed, the following message is displayed:

```
OSFNFSnnn installed NFS(tm) Utilities
(Network-Server/Communications)
```

If the NFS subset is not installed, install it by using the `setld` command. See *System Administration* for more information on installing the subset.

NFS configured?

NO

YES

Use the `rcmgr` utility to display the value of the `NFSSERVING` entry in the `/etc/rc.config.common` file:

```
# rcmgr get NFSSERVING
```

If nothing is returned, run the SysMan Menu utility to configure your NFS server. See Section 10.3 for more information.

Verify that the network software has been configured. See the solution at Network configured? in Section 15.3.

portmap daemon started?

NO

YES

Verify that the `portmap` daemon is running. Enter the following command:

```
# ps -e | grep portmap
```

If the `portmap` daemon is not running, stop and restart NFS by using the following commands:

```
# /sbin/init.d/nfs stop
# /sbin/init.d/nfs start
```

If the `portmap` daemon does not start, reboot the server.

NFS daemons registered?

NO

YES

Verify that the NFS daemons are registered with the `portmap` daemon. Enter the following commands:

```
# rpcinfo -u server_name mount
# rpcinfo -u server_name nfs
```

If neither is registered, start NFS by using the following command:

```
# /sbin/init.d/nfs start
```

To verify that the NFS daemons are running, complete the following steps:

1. Verify that a `mountd` process is running. Enter the following command:

```
# ps -e | grep mountd
```

If a `mountd` process is running, go to step 2. If no `mountd` process is running, stop and start NFS by using the following commands:

```
# /sbin/init.d/nfs stop  
# /sbin/init.d/nfs start
```

2. Verify that an `nfsd` process is running. Enter the following command:

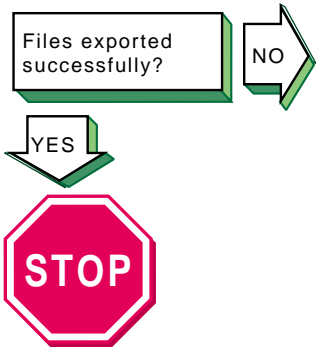

```
# ps -e | grep nfsd
```

If no `nfsd` process is running, stop and start NFS by using the following commands:

```
# /sbin/init.d/nfs stop  
# /sbin/init.d/nfs start
```

Alternatively, you can use the SysMan Menu utility to view the status of some NFS daemons. You can skip directly to the status dialog box by entering the following command:

```
# /usr/sbin/sysman nfs_daemon_status
```

Problem still exists? Report it to your service representative. See Chapter 18.

To verify that the files are being exported, complete the following steps:

1. Verify that file is being exported. Enter the following command:

```
# showmount -e
```

If the file is being exported, go to step 3.

2. If the file is not being exported, verify that the file has an entry in the `/etc/exports` file. If there is no entry in the `/etc/exports` file, edit the file and create an entry. Have the remote system mount the file.
3. If the file is being exported and the users cannot mount the file, use the `rcmgr` utility to display the value of the `NONROOTMOUNTS` entry in the `/etc/rc.config` file and determine if the users are allowed to mount the file:

```
# rcmgr get NONROOTMOUNTS
```

If the `NONROOTMOUNTS` parameter is 0, only users running as root can mount files from this server. To allow users not running as root to mount the files, enter the following command:

```
# rcmgr set NONROOTMOUNTS 1
```

4. Verify that the `mountd` daemon is running with Internet address checking on. Enter the following command:

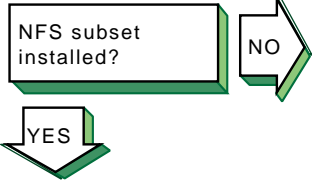

```
# ps -e | grep mountd
```

If the `-i` option is displayed, the client's name and address must be in the `/etc/hosts` file, or in the DNS or NIS `hosts` database. Only known hosts can mount the file system. If the `-d` or `-s` option is displayed, the client system must be in the same DNS domain or subdomain, respectively, as the server.

5. If the `mountd` daemon is returning stale file handles for exported files, send a hangup signal (SIGHUP) to the `mountd` daemon to force it to reread the `/etc/exports` file. Enter the following commands:

```
# ps -e | grep mountd
# kill -1 mountd_pid
```

15.12 Solving NFS Client Problems

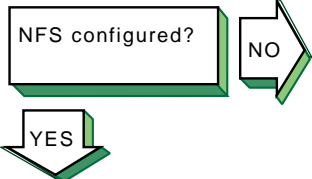

Verify that the NFS subset is installed. Enter the following command:

```
# setld -i | grep OSFNFS
```

If the subset is installed, the following message is displayed:

```
OSFNFSnnn installed NFS(tm) Utilities  
(Network-Server/Communications)
```

If the NFS subset is not installed, install it by using the `setld` command. See *System Administration* for more information on installing the subset.

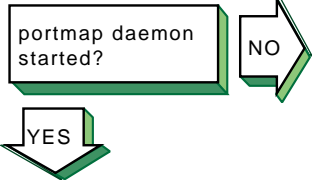

Use the `rcmgr` utility to display the value of the `NFS_CONFIGURED` entry in the `/etc/rc.config.common` file:

```
# rcmgr get NFS_CONFIGURED
```

If nothing is returned, run the SysMan Menu utility to configure your NFS client. See Section 10.3 for more information.

Verify that the network software has been configured. See the solution for Network configured? in Section 15.3.

Verify that the `portmap` daemon is running. Enter the following command:

```
# ps -e | grep portmap
```

If the `portmap` daemon is not running, stop and restart NFS by using the following commands:

```
# /sbin/init.d/nfs stop  
# /sbin/init.d/nfs start
```

If the `portmap` daemon does not start, reboot the client.

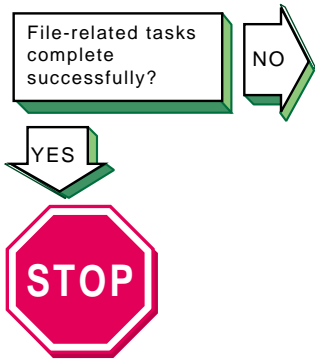

If the client cannot mount a remote file system or directory, complete the following steps:

1. If an error message is displayed on the user's terminal, see Appendix D for the error message and a description.
2. Verify that the remote NFS server is on your local network and in your `hosts` database.
3. Verify that the server daemons on the remote system are running. Enter the following command:

```
# rpcinfo -p server_name
```
4. Verify that the server is exporting the files you want to mount. Enter the following command:

```
# showmount -e server_name
```
5. See the solutions for solving NFS server problems in Section 15.11. If the server is running and you still have problems, verify the Ethernet connections and the Internet connections between the client system and the remote server.
6. Determine if other clients on the network are having problems with the remote server.
7. Verify that the mount command line or the entry in the `/etc/fstab` file is correct, and verify the following:
 - a. The host name matches the name of the remote NFS server.
 - b. The mount point exists on your system.
8. If you get an authentication error, verify the following:
 - a. If you are not a superuser, the server allows nonroot mounts.
 - b. Your host name is in the server's `hosts` database.
 - c. If your system is not in the same domain as the server, the server performs domain checking. See `mountd(8)` for more information on server options.

Problem still exists? Report it to your service representative. See Chapter 18.

If application programs that perform file-related tasks do not complete their tasks or take a long time to do so, complete the following steps:

1. If an error message is displayed on the user's terminal, see Appendix D for the error message and a description.
2. Verify that the server is running. See the solutions for solving NFS server problems in Section 15.11. If the server is running, verify that the `nfsd` daemon is accumulating CPU time. If it is not, kill it and restart it. If this does not solve the problem, reboot the server. If the remote file systems or directories are mounted with the `hard` option, the program continues when the server is running once again.
3. Determine if other clients on the network are having problems with the remote server. If they are not, verify that the Ethernet connections and the internet connections between the client system and the remote server are working properly.
4. Determine if any `nfsiod` daemons are running. Enter the following command:

```
# ps -e | grep nfsiod
```

If no `nfsiod` daemons are running, start some. Enter the following command:

```
# /usr/sbin/nfsiod 7
```

Although the `nfsiod` daemons are not necessary for a client, they perform read-ahead and write-behind functions, which might make I/O faster.

5. If file access requests succeed but file locking requests hang indefinitely, verify that the local `rpc.statd` and `rpc.lockd` daemons are running. Enter the following commands:

```
# ps -e | grep rpc.statd
```

```
# ps -e | grep rpc.lockd
```

If they are not running, start them. Enter the following commands:

```
# /usr/sbin/rpc.statd
```

```
# /usr/sbin/rpc.lockd
```

Also, verify that the local `rpc.statd` and `rpc.lockd` daemons are running on the server. Enter the following commands:

```
# rpcinfo -p server_name | grep status
```

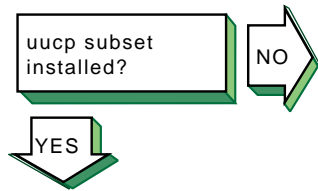

```
# rpcinfo -p server_name | grep lockmgr
```

If they are not running, contact the server's system administrator.

Alternatively, you can use the SysMan Menu utility to view the status of some NFS daemons. You can skip directly to the status dialog box by entering the following command:

```
# /usr/sbin/sysman nfs_daemon_status
```

15.13 Solving UUCP Problems

Verify that the uucp subset is installed. Enter the following command:

```
# setld -i | grep OSFUUCP
```

If the subset is installed, the following message is displayed:

```
OSFUUCPnnn installed UNIX(tm)-to-UNIX(tm) Copy  
Facility (General Applications)
```

If the uucp subset is not installed, install it by using the `setld` command. See *System Administration* for more information on installing the subset.

Verify that the Basic Networking Services subset (containing the `tip` and `cu` utilities) is installed. Enter the following command:

```
# setld -i | grep OSFCLINET
```

If the subset is installed, the following message is displayed:

```
OSFCLINETnnn installed Basic Networking Services  
(Network-Server/Communications)
```

If the Basic Networking Services subset is not installed, install it by using the `setld` command. See *System Administration* for more information on installing the subset.

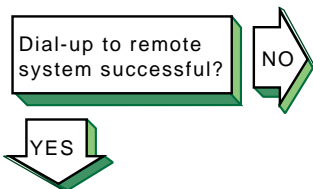

Look for entries in the `Permissions`, `Devices`, and `Systems` files in the `/usr/lib/uucp` directory. If there are no entries, run the `uucpsetup` script. See Section 11.3 for more information.

Configure the network hardware as follows:

- Direct connections to remote host — Use a null modem or modem eliminator cable to connect your system to the remote host.
- Phone line connection to remote host — Use a cable to connect your system to a modem and another cable to connect your modem to a phone line. The modem you use must be compatible with the modem at the remote host. Make sure the modem is configured as follows:
 - Forced data set ready (DSR) is disabled.
 - Full or verbose status messages are enabled.
 - Character echo is disabled.
 - Use 8-bit characters with no parity.
 - XON/XOFF flow control is disabled.
- TCP/IP connection to remote host — Use a cable to connect your system to the network. Then, run the Network Configuration application to configure the network. See Section 2.3 for more information on setting up the network.

If you cannot dial up the remote system, verify the following:

1. Make sure that the setup parameters (such as speed, parity, modem control, flow control, and other terminal characteristics) on the local and remote ends are properly defined for your modem type.
2. Dial the number to the remote node. If you do not get an “Attached” message or a login prompt, plug a telephone handset into the local telephone line to verify that there is a dial tone. If you do not hear a dial tone, call your local carrier to fix this problem. If you get no message, verify that the cabling between the local system and the modem is properly installed and undamaged.
3. If you get a dial tone, check that your modem is operational and perform diagnostic tests on your modem. See the modem manual for more information.
4. From another handset, dial the local telephone line. If the local telephone rings and you can carry on a conversation, the telephone line on the local end is good. If you cannot pass voice traffic, or if there is no ring, call your local carrier to fix this problem.
5. Repeat steps 2 and 3 on the remote node to resolve problems with the remote end.
6. If the telephone line is operational, verify that the remote modem is set up to automatically answer incoming calls when the system raises the data terminal ready (DTR) signal. The system raises the DTR signal by issuing a `uucpgetty` or `getty` command on the port.

Run the `uucp` tests to test the connection to the remote system. See Section 16.7 and Section 16.8.

If you can establish a connection, but your file transfer eventually times out and exits, attempt to set the type of flow control that the `uucico` daemon uses, as described in Section 11.3.5 and the `uucico(8)` reference page.

If the `tip` command does not execute successfully, complete the following steps:

1. Verify that the system name, connection speed, and phone number are in the `/etc/remote` file or that the system name and connection speed are in the `/etc/remote` file and the phone number is in the `/etc/phones` file. See `remote(4)` and `phones(4)` for more information.
2. Examine the `at` entry in the `/etc/remote` file. If the entry is correct, create an entry for the modem in the `/etc/acucap` file. See `acucap(4)` for more information.
3. Verify that the remote system is configured to answer incoming calls.

Problem still exists? Report it to your service representative. See Chapter 18.

15.14 Solving NTP Problems

NTP configured?

NO

YES

Use the `rcmgr` utility to display the value of the `XNTPD_CONF` entry in the `/etc/rc.config` file:

```
# rcmgr get XNTPD_CONF
```

If nothing is returned, run the SysMan Menu utility to configure NTP. See Section 12.3 for more information.

NTP daemon started?

NO

YES

Verify that an `xntpd` process is running. Enter the following command:

```
# ps -e | grep xntpd
```

Alternatively, you can use the SysMan Menu utility to view the status of the `xntpd` daemon. You can skip directly to the status dialog box by entering the following command:

```
# /usr/sbin/sysman ntp_status
```

If no `xntpd` process is running, start NTP by using the following command:

```
# /sbin/init.d/xntpd start
```

Server found?

NO

YES

If the `ntpq` or `xntpd` command cannot find the server host, the following message is displayed:

```
***Can't find host hostname
```

The `hostname` is not in the `/etc/hosts` file, the DNS `hosts` database, or the NIS `hosts` database. Edit the appropriate file or database and add an entry for the server host.

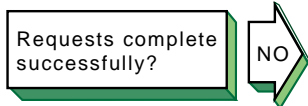

If you run one of the monitor programs and in the output from the `peers` command the reach column contains zeros (0s), complete the following steps:

1. Contact the system administrator of the server and verify which NTP daemon the server is running. The entry for the server in the `/etc/ntp.conf` file must contain the phrase `version x` after the server name, as follows:

```
server host1 version x
```
2. Look in the `/etc/hosts` file and verify that there is an entry for each NTP server specified in the `/etc/ntp.conf` file. If you are using either DNS or NIS for host information, verify that the hosts database has an entry for each NTP server.

If the `xntpdc hostname` command does not display any information, verify that the `hostname` server is running NTP.

If the `ntpq` or `xntpd` request times out, the following message is displayed:

```
hostname: timed out, nothing received  
***Request timed out
```

Complete the following steps:

1. The `hostname` is not running the `xntpd` daemon. Contact the system administrator for that system.
2. The network connection has gone down. See the solutions for Host reachable? at the beginning of this chapter.

If you still cannot solve the problem, complete the following steps:

1. Examine the `/etc/rc.config` file to make sure it contains entries similar to the following:

```
XNTPD_CONF="YES"  
export XNTPD_CONF  
XNTP_SERV1=server1  
export XNTP_SERV1  
XNTP_SERV2=server2  
export XNTP_SERV2  
XNTP_SERV3=server3  
export XNTP_SERV3  
XNTPD_OPTS="-g"  
export XNTPD_OPTS
```

If this entry does not exist or is incorrect, run the SysMan Menu utility to configure NTP. See Section 12.3 for more information.

2. Examine the `/etc/ntp.conf` file and make sure the information in it is accurate. It must contain entries for hosts running NTP with which you want to synchronize system time. Make sure the correct version number is specified for each server and peer. Use the SysMan Menu utility to correct any entries. See Section 12.3 for information.
3. Look in the `/var/adm/syslog.dated/current/daemon.log` file for information about NTP problems on the system. See Section 16.10 for more information.

Problem still exists? Report it to your service representative. See Chapter 18.

15.15 Solving SLIP Problems

Verify that the correct number of Serial Line Internet Protocol (SLIP) pseudodevices are supported in the kernel by using the `netstat -in` command. If SLIP is supported, information similar to the following is displayed for each interface:

```
s10* 296 <Link> 0 0 0 0 0
```

The `s1` prefix indicates that SLIP is supported on the system. In this example there is one SLIP interface.

If you need additional SLIP interfaces, specify them by adding the `nslip=x` attribute under the `net:` subsystem in the `/etc/sysconfigtab` file. See *System Administration* for information on adding more SLIP interfaces.

On systems with 24 megabytes of memory, SLIP is not configured into the kernel. To add SLIP into the kernel, edit the system configuration file (`/usr/sys/confhostname`) and add the following entry:

```
options SL
```

See *System Administration* for more information.

Configure the network hardware as follows:

- Verify that you are using the correct hardware. See Section 6.1.2.1 for more information.
- Make sure the modem is configured as follows:
 - Use 8-bit characters with no parity.
 - Software flow control (XON/XOFF) is disabled.
 - For dial-in systems, follow the guidelines in Section 6.1.3.1.
 - For dial-out systems, follow the guidelines in Section 6.1.3.2.

If a remote system cannot dial in to your system successfully, complete the following steps:

1. Edit the `/etc/slhosts` file and include the `debug` option in the `login` entry for the host that cannot log in. See `slhosts(4)` for more information.
2. Instruct the remote user to dial in again.
3. Look in the `/var/adm/syslog.dated/current/daemon.log` file for information on SLIP problems on the dial-in system. See Section 16.10 for more information.

If you cannot dial out to the remote system, complete the following steps:

1. Verify that the modem is working correctly.
Edit the `/etc/acucap` file and include the `db` option in your modem's entry. This option displays useful information for debugging a new entry. See `acucap(4)` for more information.
2. Verify SLIP setup. Do the following:
 - a. Edit the `startslip` dial-out script file and specify the debug subcommand and a debug log file.
 - b. Try to dial out again.
 - c. Look in the debug log file for information about SLIP dial-out problems.

If you cannot communicate with the remote host and none of the debug messages shows an error, complete the following steps:

1. Verify that the IP addresses and netmasks are correct on both ends of the connection.
2. Examine the following SLIP configuration parameters at each end of the connection:
 - Internet Control Message Protocol (ICMP) traffic suppression — If enabled at either end of the connection, the `ping` command will fail.
 - TCP header compression — If enabled at one end, TCP header compression must be enabled or autoenabled on the other end.

If you can communicate with the remote host but not the network connected to the remote host, complete the following steps:

1. If your local system is using the remote system as a gateway system, issue the `netstat -rn` command on the local system to verify that the remote SLIP address is the default gateway.
2. On the gateway system (remote system), issue the `iprsetup -d` command to see if the `ipforwarding` and `ipgateway` variables are on. If the variables are off, use the `iprsetup -s` command to turn them on.
3. On the gateway system, verify that the `gated` daemon is running. See `gated(8)` for more information.

Problem still exists? Report it to your service representative. See Chapter 18.

If the `startslip` command does not complete successfully, complete the following steps:

1. Build your kernel with the `PACKETFILTER` option.
2. Use the `tcpdump` command to examine packets sent and received through the SLIP interface. See `tcpdump(8)` for more information.

15.16 Solving PPP Problems

PPP supported in kernel?

NO

YES

Verify that the Point-to-Point Protocol (PPP) is supported in the kernel by using the `sysconfig -s | fgrep ppp` command. If PPP is supported, information similar to the following is displayed:

```
ppp: loaded and configured
```

If PPP is not supported, add options PPP into the `/sys/conf/MACHINE` system configuration file and rebuild the kernel.

Network hardware configured?

NO

YES

Configure the network hardware as follows:

- Direct connections to remote host — Use a null modem or modem eliminator cable to connect your system to the remote host.
- Phone line connection to remote host — Use a cable to connect your system to a modem and another cable to connect your modem to a phone line. The modem you use must be compatible with the modem at the remote host. Make sure the modem is configured as follows:
 - Use 8-bit characters with no parity.
 - All flow control is disabled.

Connection to remote system successful?

NO

YES

If you are logging messages to the console and the link comes up successfully, the following messages are displayed on the console:

```
Local IP address: xx.xx.xx.xx  
Remote IP address: yy.yy.yy.yy
```

If the link does not come up, look at the following:

- Verify that the serial connection is set up successfully. Use the `chat -v` command to log the characters the `chat` program sends and receives.
- Verify that `pppd` starts on the remote system. Use the `chat -v` command to log the characters the `chat` program sends and receives.
- Examine the PPP negotiation between the two peers. Use the `pppd` command with the `debug` option to log the contents of all control packets sent and received.

Network applications complete successfully?

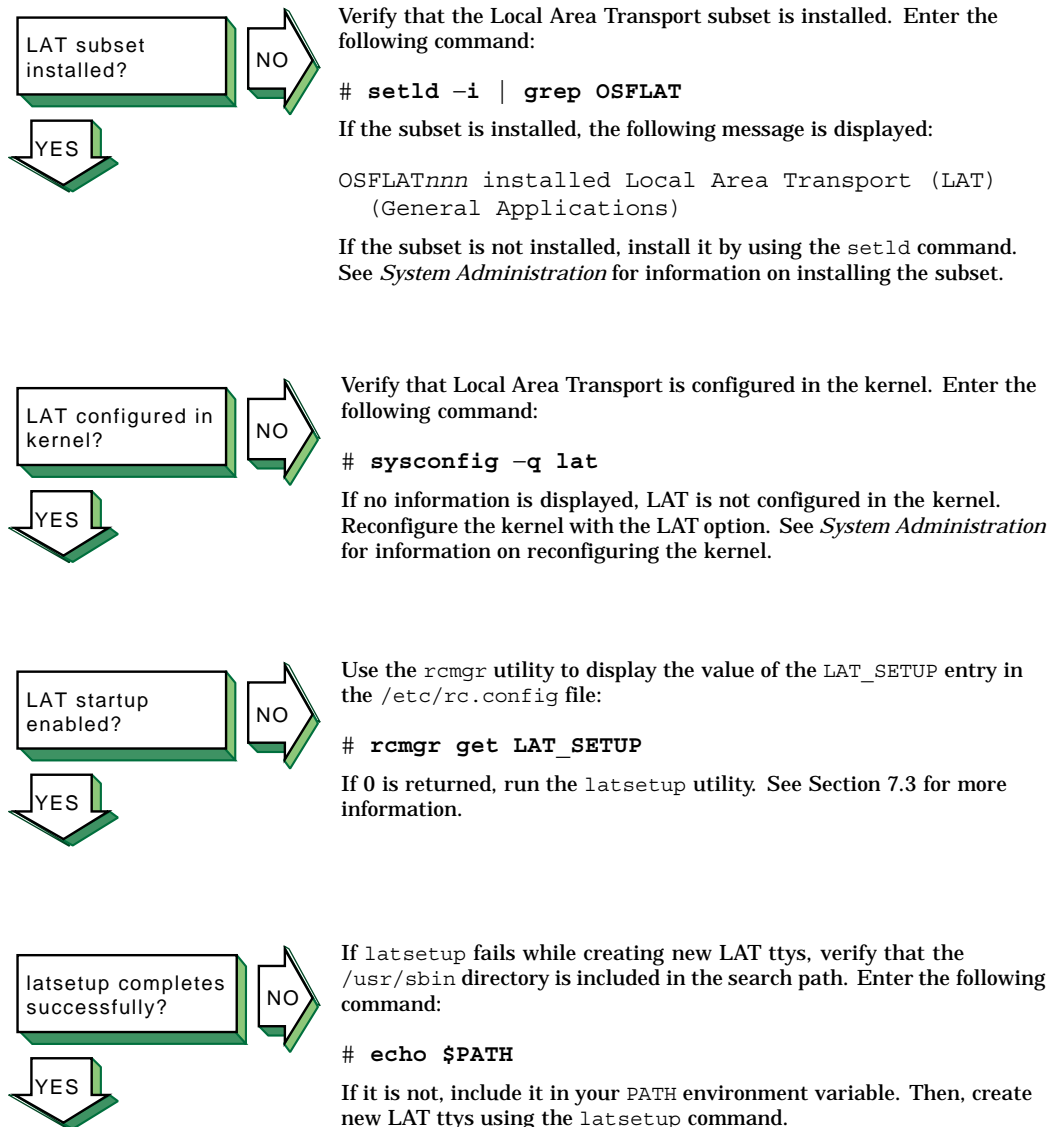

Problem still exists? Report it to your service representative. See Chapter 18.

If network applications do not work successfully, this might indicate a problem with assigning IP addresses or routing. Do the following:

1. Use the `netstat -i`, `netstat -r`, `ping`, and `tracert` commands to diagnose the problem.
2. If you can communicate with the peer machine but not with machines beyond that in the network, there is a routing problem. For instances where the local machine is connected to the Internet through the peer, do the following:
 - a. Assign the local machine an IP address on the same subnet as the remote machine.
 - b. Run the local `pppd` daemon with the `defaultroute` option.
 - c. Run the remote `pppd` daemon with the `proxyarp` option.
 - d. On the peer system (remote system), issue the `iprsetup -d` command to determine if the `ipforwarding` and `ipgateway` variables are on. If these variables are off, use the `iprsetup -s` command to turn them on.

15.17 Solving LAT Problems

Verify that LAT has been started. Enter the following command:

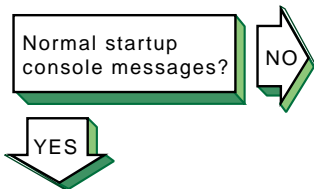

```
# latcp -d
```

If LAT is running, the following line is displayed:

```
LAT Protocol is active
```

If LAT was not started, start it. Enter the following command:

```
# latcp -s
```

If LAT starts and messages are continually displayed on the system console, look for the following messages and perform the required steps:

Message 1

```
getty: cannot open "/dev/lat/xx".  
errno: 2
```

This means a LAT terminal device file (tty) does not exist and the `/etc/inittab` file contains an entry for this file. The `latsetup` utility will also report that no LAT entries are available. Do the following:

1. Edit the `/etc/inittab` file and remove the LAT getty entries.
2. If LAT terminal devices are required, create the LAT terminal device files and corresponding entries in the `/etc/inittab` file by using the `latsetup` command. See `latsetup(8)` for information.

Message 2

```
getty: cannot open "/dev/lat/xx".  
errno: 19
```

This means the kernel was not configured with the LAT option and the `/etc/inittab` file contains at least one LAT getty entry. Do either of the following:

- Configure LAT into the kernel. See *System Administration* for information on configuring LAT into the kernel.
- Remove the LAT getty entries from the `/etc/inittab` file, either manually or by using the `latsetup` command.

Message 3

```
INIT: Command is respawning too rapidly.
```

The following meanings are possible:

- You are using an optional service name, such as `lattelnet`, and it is incorrectly defined. Do the following:
 1. Verify that the optional service name defined by the `latcp -A` command is correct by using the `latcp -d` command.
 2. Edit the `/etc/inittab` file and verify that a LAT entry has the optional service name specified correctly.
- An attempt was made to use a nonexistent LAT terminal device (tty). Do the following:
 1. Edit the `/etc/inittab` file and remove the entry with the nonexistent terminal device name.
 2. If LAT terminal devices are required, create the LAT terminal device files and corresponding entries in the `/etc/inittab` file by using the `latsetup` command. See `latsetup(8)` for more information.

If the user cannot connect to or display a service from a terminal server via LAT, complete the following steps on the system:

1. Verify that the service name is correct, using the `latcp -d` command. If the service name is incorrect, delete the service with the incorrect name. Enter the following command:

```
# latcp -D -aservice_name
```

Then, add a service with the correct name. Enter the following command:

```
# latcp -A -aservice_name
```

See `latcp(8)` for more information.

2. Display the group codes for the service to which the user is attempting to connect, using the `latcp -d` command. Check if any group code matches a group displayed by using the `show port` command at the terminal server. If no group code matches, do either of the following:
 - Add at least one group displayed by the port to the service. Enter the following command:

```
# latcp -glist -aservice_name
```

- Change the port characteristics at the terminal server by adding a group that matches the service.

See `latcp(8)` for more information.

3. Check if LAT is started on the system. If it is not, start it. Enter the following command:

```
# latcp -s
```

4. If the problem persists, restart LAT. Enter the following command:

```
# latcp -s
```

If problems occur when using an optional service, complete the following steps:

1. Verify that the service was added as an optional service. Enter the following command:

```
# latcp -d
```

Look for the following line:

```
Service name: name (Optional)
```

If `Optional` is not displayed, the optional service was not defined with the `-o` option. Delete the service. Enter the following command:

```
# latcp -D -aservice_name
```

Then, add the service with the correct name and the `-o` option. Enter the following command:

```
# latcp -A -aservice_name -o
```

See `latcp(8)` for more information.

2. Verify that the optional service name matches the name defined in the `/etc/inittab` file. If it does not, do either of the following:

- Edit the `/etc/inittab` file and specify the optional service name.
- Delete the service. Enter the following command:

```
# latcp -D -aservice_name
```

Then, add the service with the correct name and the `-o` option. Enter the following command:

```
# latcp -A -aservice_name -o
```

See `latcp(8)` for more information.

If the user cannot connect to a host using LAT, the following messages are displayed:

```
Connection
to node-name not established.
Service in use.
```

The `/etc/inittab` file does not contain a sufficient number of `getty` entries. Create more LAT terminal devices (`ttys`) and add their corresponding entries into the `/etc/inittab` file by using the `latsetup` command. Then, restart LAT to advertise the available services. Enter the following command:

```
# latcp -s
```

See Section 7.3 for information.

If a host-initiated connection fails, verify that the port, host, and service names are specified correctly. Enter the following command:

```
# latcp -d -P -L
```

If these names are not specified correctly, delete the application ports with the incorrect names. Enter the following command:

```
# latcp -D -pport_name
```

Then, add the application ports, using correct spelling. To create the application port by specifying the remote port to which the LAT terminal device is to be mapped, use the following command:

```
# latcp -A -plocal_port -Hnode -Rrem_port
```

Or, to create the application port by specifying the remote service name to which the LAT terminal device is to be mapped, use the following command:

```
# latcp -A -plocal_port -Hnode -Vsvc_name
```

See `latcp(8)` for information.

Note

When you delete an application port for a LAT printer, any print operations that are currently executing continue until the printer buffer is empty. The print job might not be complete.

If you print a file to a printer attached to a LAT application port, the printer is online, and no printing occurs, look at the status of the print queue. Enter the following command:

```
# lpc status
```

The following line might be displayed:

```
waiting for printer to become ready (offline ?)
```

If this line is displayed, verify that LAT has been started. Enter the following command:

```
# latcp -d
```

If LAT has not been started, start it. Enter the following command:

```
# latcp -s
```

If problems are encountered with the LAT/Telnet gateway, look in the `/var/adm/syslog.dated/current/daemon.log` file for error messages. Use the error messages to diagnose the problem. See Section 16.10 for more information on viewing the `daemon.log` file. The `lattelnet` utility uses the syslog message priority of `LOG_INFO`. For example, if you edit a LAT terminal entry in the `/etc/inittab` file, reassign it to `lattelnet` while a `getty` process is still active for the terminal, and a user tries to connect to `lattelnet`, the connection will fail. The following error message is posted in the `daemon.log` file:

```
No such file or directory
```

Terminate the `getty` process for the terminal port.

If the LAT connection terminates abnormally, complete the following steps:

1. Examine the LAT terminal device (`ttys`) files for duplicate minor numbers. Enter the following command:

```
# ls -l /dev/latt/*
```

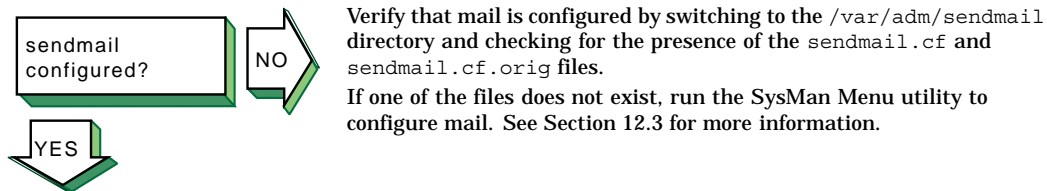

If any exist, remove the duplicate device files, leaving the original file.

2. Look in the `/etc/inittab` file for duplicate LAT entries. Remove the duplicate entries, leaving the original entry.

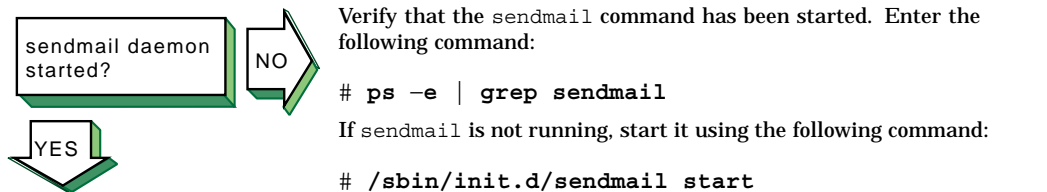

Problem still exists? Report it to your service representative. See Chapter 18.

15.18 Solving sendmail Problems

Verify that mail is configured by switching to the `/var/adm/sendmail` directory and checking for the presence of the `sendmail.cf` and `sendmail.cf.orig` files.
If one of the files does not exist, run the SysMan Menu utility to configure mail. See Section 12.3 for more information.

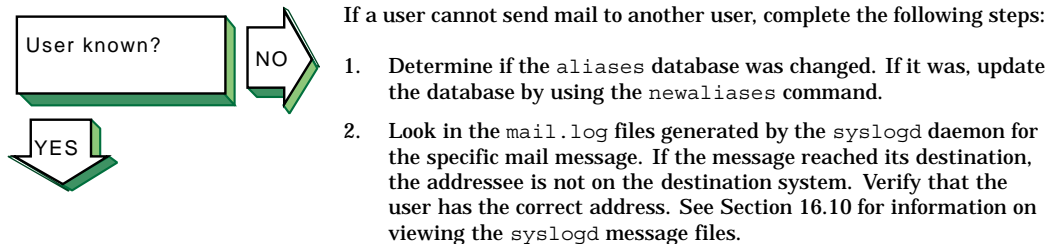

Verify that the `sendmail` command has been started. Enter the following command:

```
# ps -e | grep sendmail
```

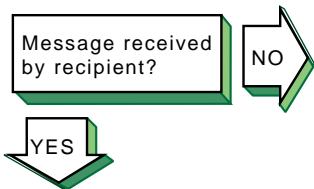

If `sendmail` is not running, start it using the following command:

```
# /sbin/init.d/sendmail start
```

If a user cannot send mail to another user, complete the following steps:

1. Determine if the `aliases` database was changed. If it was, update the database by using the `newaliases` command.
2. Look in the `mail.log` files generated by the `syslogd` daemon for the specific mail message. If the message reached its destination, the addressee is not on the destination system. Verify that the user has the correct address. See Section 16.10 for information on viewing the `syslogd` message files.

If you sent a mail message and the recipient did not receive it, complete the following steps:

1. Verify that the address is correct.
2. Verify that the remote node is reachable by using the `ping` command.
3. Look in the `mail.log` files generated by the `syslogd` daemon for the sender's user name. See Section 16.10 for information on viewing the `syslogd` message files. If you find an entry, write down the message ID. If no entry is found, send the message again.
4. Using the message ID, search through the `mail.log` files for the "from" and "to" entries. If you find a "from" entry but no "to" entry, either `sendmail` did not receive the message or the message was corrupted. Look in the `/var/spool/mqueue` directory for files containing the message ID by entering the following command:

```
# ls -l /var/spool/mqueue/*message_ID
```

Possible outcomes include:

- The `qf*message_ID` control file is present but the `(df*message_ID)` data file is not. The message was lost.
- A "from" entry and a "to" entry exist, and the status is deferred. The message is in the queue.
- There is no corresponding sent entry. Use the `mailq` command to report the reason for the deferral.
- A "from" entry and a "to" entry exist, the status is sent, and the message was delivered. If a local delivery, the message reached the destination. If a remote delivery, have the system administrator on the remote host search for the message.

If `sendmail` is not working correctly, complete the following steps:

1. Look in the rejected message for an error message.
2. Look for error messages in the `mail.log` files generated by the `syslogd` daemon. See Section 16.10 for information on viewing the `syslogd` message files.

See Appendix F for a list of `sendmail` error messages.

Problem still exists? Report it to your service representative. See Chapter 18.

15.19 Solving POP and IMAP Problems

Verify that the Additional Networking Services subset is installed on the server. Enter the following command:

```
# setld -i | grep OSFINET
```

If the subset is installed, the following message is displayed:

```
OSFINETnnn installed Additional Networking Services  
(Network-Server/Communications)
```

If the subset is not installed, install it by using the `setld` command. See *System Administration* for more information on installing the subset.

If the user cannot connect to the Post Office Protocol (POP) or Internet Message Access Protocol (IMAP) server:

1. Verify that the user is connecting to the correct server.
2. Verify that the server is reachable by using the `ping` command.
3. Verify the POP or IMAP entries in the `/etc/passwd`, `/etc/services`, and `/etc/inetd.conf` files on the server, as described in Section 13.4.1 and Section 13.5.1. If necessary, restart network services to effect the changes.

Verify that the user has specified a valid user name and password. Use the `mailusradm` utility to verify the existence of the POP or IMAP account on the server or to change the password, if necessary.

If a user cannot retrieve mail from the POP or IMAP server:

1. Verify that the user has a POP3 or IMAP4-compatible mail program.
2. For POP, look in the `/usr/spool/mail` directory for a lock file named after the user. If one exists, delete the file to remove the lock.
3. For IMAP, verify that the user has proper ACLs for the IMAP mail folder by using the `cyradm` command. See Section 13.5.8 and `cyradm(8)`.
4. Look in the `mail.log` files generated by the `syslogd` daemon for error messages related to POP or IMAP. See Section 16.10 for information on viewing the `syslogd` message files.
5. Create a directory with the user's account name in the `configdirectory/log` directory (usually, the log directory is `/var/imap/log`, see the `/etc/imapd.conf` file for the location of the `configdirectory` on your system). When the user attempts to access the server, examine the log of the session to see where the error occurs.

If the user is not receiving new mail:

1. Look in the `mail.log` files generated by the `syslogd` daemon for errors. See Section 16.10 for information on viewing the `syslogd` message files.
2. For IMAP, look at the user and quota configuration directories to verify that subdirectories `a` through `z` exist (see Section 13.5.2), that the subdirectories contain the proper files for the given user (see Section 13.5.6), and that all directories and files under `/var/imap` and `/var/spool/imap` are owned by the `imap` user.

If the user cannot send mail:

1. Verify that the user is connecting to the correct SMTP server.
2. Verify that the SMTP server is reachable by using the `ping` command.
3. See Section 15.18 on solving `sendmail` problems.

Problem still exists? Report it to your service representative. See Chapter 18.

Using the Problem Solving Tools

To help you resolve problems with network hardware, the network itself, and various network services, the operating system provides problem solving tools to help you do the following tasks:

- Detect network interface failures
- Test access to network hosts on the Internet network
- Display network statistics
- Display and modify the Internet to Ethernet translation tables
- Display a datagram's route to a network host
- Display headers of packets on the network
- Test a UUCP remote connection
- Monitor a UUCP file transfer
- Display the error log file
- Display the `syslogd` daemon message files

16.1 Detecting Network Interface Failures

Use the Network Interface Failure Finder (NIFF) utility to detect and report possible failures in network interface cards or their connections.

Once you specify an interface to monitor by using the `niffconfig` command, the kernel Traffic Monitor Thread (TMT) checks the connectivity of the monitored interface and, if necessary, informs the NIFF daemon (`niffd`) to generate traffic for the network interface that is determined to have failed. If the `niffd` daemon cannot get the interface packet counters to increment, signifying that the interface is alive and well, it reports the problem to the Event Manager subsystem.

You can use NIFF as a standalone reporting utility, or you can configure a NetRAIN interface (as discussed in Section 2.4), a virtual interface which incorporates the NIFF technology and provides automatic failover for selected network interfaces on your system.

See `niff(7)` and `niffconfig(8)` for more information about the NIFF utility. See Appendix A and `netstat(1)` for more information about monitoring network interfaces.

16.2 Testing Access to Internet Network Hosts

Use the `ping` command to test your system's ability to reach a host on the Internet network. The `ping` command has the following syntax:

```
/usr/sbin/ping [ options... ] hostname
```

Table 16–1 describes some of the `ping` command options.

Table 16–1: Options to the ping Command

Option	Function
<code>-c count</code>	Specifies the number of ECHO RESPONSE packets to send and receive.
<code>-I interface</code>	Specifies the interface over which to send packets.
<code>-R</code>	Includes the RECORD_ROUTE option in the packet and displays the route buffer on returned packets.
<code>-r</code>	Executes the <code>ping</code> command for a host directly connected to the local host. With this option, the <code>ping</code> command bypasses normal routing tables and sends the request directly to a host on an attached network. If the host is not on a directly attached network, the local host receives an error message.
<code>-V</code>	Specifies the IP version number (4 or 6) of the address returned by the resolver when a host name has both IPv4 and IPv6 addresses. By default, <code>ping</code> tries to resolve host names as an IPv6 address then IPv4 address.

The `ping` command sends an Internet Control Message Protocol (ICMP) echo request to the host specified. When the request is successful, the remote host sends the data back to the local host. If the remote host does not respond to the request, the `ping` command does not display any results.

To terminate the `ping` command output, press `Ctrl/C`. When terminated, the `ping` command displays statistics on packets sent, packets received, the percentage of packets lost, and the minimum, average, and maximum round-trip packet times.

You can use the output from the `ping` command to help determine the cause of direct and indirect routing problems such as an unreachable host, a timed-out connection, or an unreachable network.

When using the `ping` command for fault isolation, first test the local host to verify that it is running. If the local host returns the data correctly, use the `ping` command to test remote hosts farther and farther away from the local host.

If you do not specify command options, the `ping` command displays the results of each ICMP request in sequence, the number of bytes received from the remote host, and the round-trip time on a per-request basis.

The following example shows the output from a `ping` command to a host named `host1`:

```
% ping host1
PING host1.corp.com (16.20.32.2): 56 data bytes
64 bytes from 16.20.32.2: icmp_seq=0 ttl=255 time=11 ms
64 bytes from 16.20.32.2: icmp_seq=1 ttl=255 time=3 ms
64 bytes from 16.20.32.2: icmp_seq=2 ttl=255 time=7 ms
64 bytes from 16.20.32.2: icmp_seq=3 ttl=255 time=3 ms
64 bytes from 16.20.32.2: icmp_seq=4 ttl=255 time=7 ms
64 bytes from 16.20.32.2: icmp_seq=5 ttl=255 time=3 ms
Ctrl/C
---host1.corp.com PING Statistics---
6 packets transmitted, 6 packets received, 0% packet loss
roundtrip (ms) min/avg/max = 3/5/11 ms
```

The `ping` command accepts an IPv4 address, IPv6 address, or node name on the command line. The following example specifies an IPv6 address:

```
# ping -c 2 5F00:2100:108C:4000:8C40:800:2B2D:2B2
PING (5F00:2100:108C:4000:8C40:800:2B2D:2B2): 56 data bytes
64 bytes from 5F00:2100:108C:4000:8C40:800:2B2D:2B2: icmp6_seq=0
    hlim=58 time=17 ms
64 bytes from 5F00:2100:108C:4000:8C40:800:2B2D:2B2: icmp6_seq=1
    hlim=58 time=17 ms
---5F00:2100:108C:4000:8C40:800:2B2D:2B2 PING Statistics---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip (ms) min/avg/max = 17/17/17 ms
```

The command sends appropriate `ECHO_REQUEST` packets based on the address family being used. In some cases, a single node name might resolve to both an IPv4 and IPv6 address. Use the `-V4` or `-V6` option specify which address to use.

You can also use the `-I` flag to force the use of a specific interface. For example:

```
# ping -I ln0 FE80::800:2B2D:2B2
```

See `ping(8)` for more information on this command and its options.

16.3 Displaying Network Statistics

Use the `netstat` command to display network statistics for sockets, interfaces, and routing tables. The `netstat` command accepts either the `-f inet` or `-f inet6` flag to limit the data displayed to either IPv4 or IPv6, respectively. For example, the `netstat -f inet6 -rn` command displays

only IPv6 routing table entries, as opposed to the default, which displays both IPv4 and IPv6 entries.

The `netstat -s` command displays statistics for all protocols, including IPv6 and ICMPv6. See `netstat(1)` for more information.

16.4 Displaying and Modifying the Internet (IPv4) to MAC Address Translation Tables

You can display and modify the Internet to Media Access Control (MAC) address translation tables used by the Address Resolution Protocol (ARP) to help diagnose direct IPv4 routing problems resulting from the following circumstances:

- A source host has incorrect Ethernet address information for a destination host
- Two hosts have the same IPv4 address

Although you can work around this problem by modifying the translation tables, it is best to change one host's IPv4 address to permanently resolve the conflict.

Use the `arp -a` to display the entries in the Internet to MAC address translation tables. To modify the tables, log in as root and use the `arp` command as follows:

```
/usr/sbin/arp [ options ] hostname
```

The following example shows the Ethernet address for an IPv4 host named `host1`. The system response tells you that the Ethernet address for `host1` is `aa-00-04-00-8f-11`.

```
# /usr/sbin/arp host1
host1 (16.20.32.2) at aa:0:4:0:8f:11 permanent
```

The following example shows how to temporarily add `host9` to the system translation tables:

```
# /usr/sbin/arp -s host9 0:dd:0:a:85:0 temp
```

The following example shows how to remove `host8` from the system translation tables:

```
# /usr/sbin/arp -d host8
```

See `arp(8)` for more information on this command.

16.5 Displaying a Datagram's Route to a Network Host

You can display a datagram's route to a network host to manually test, measure, and manage the network.

To display a datagram's route, use the `traceroute` command with the following syntax:

```
traceroute [ options... ] hostname [ packetsize ]
```

Table 16–2 describes some of the `traceroute` command options.

Table 16–2: Options to the `traceroute` Command

Option	Function
<code>-m max_ttl</code>	Sets the maximum time-to-live (<code>ttl</code>) used in outgoing probe packets. The <code>ttl</code> parameter specifies the maximum number of hops a packet can take to reach its destination. The default is 30 hops.
<code>-n</code>	Displays hop addresses numerically only, rather than both numerically and symbolically.
<code>-p port</code>	Sets the base User Datagram Protocol (UDP) port number to be used in outgoing probe packets. The default is 33434. The port information is used to select an unused port range if a port in the default range is already used.
<code>-r</code>	Bypasses the normal routing tables and sends the probe packet directly to a host on an attached network. If the host is not on a directly attached network, the <code>traceroute</code> command returns an error.
<code>-s IP_address_number</code>	Uses the specified IP address number as the source address in outgoing probe packets. On hosts with more than one IP address, this option forces the <code>traceroute</code> command to use the specified source address rather than any others the host might have. If the IP address is not one of the receiving host's interface addresses, the command returns an error and does not send a probe packet.
<code>-t type-of-service value</code>	Sets the type-of-service in probe packets to the specified value. The default is zero. The value must be a decimal integer in the range 0--255. This option tells you if different types of service result in different paths. This option is available only in Berkeley UNIX (4.4BSD) environments. Not all types of service are legal or meaningful. Useful values for this option are 16 (low delay) and 8 (high delay). See RFC 791, <i>Internet Protocol</i> for more information on types of service.
<code>-v</code>	Displays verbose output, which includes received ICMP messages other than <code>time exceeded</code> and <code>port unreachable</code> .

Table 16–2: Options to the traceroute Command (cont.)

Option	Function
<code>-V version</code>	Specifies the IP version number (4 or 6) of the address returned by the resolver when a host name has both IPv4 and IPv6 addresses. By default, <code>traceroute</code> tries to resolve host names as an IPv6 address then IPv4 address.
<code>-w wait_time</code>	Sets the time (in seconds) to wait for a response to a probe. The default is 3 seconds.
<code>packetsize</code>	Sets the packet size (in bytes) for the probe packet. The default size is 38 bytes.

The `traceroute` command sends UDP packets (known as probe packets) to an unused port on the remote host, and listens for ICMP replies from IP routers. It sends the probe packets with a small `ttl` parameter, which specifies the maximum number of hops a packet can take to reach its destination. The `traceroute` command starts by specifying a `ttl` of one hop and it increases the `ttl` by one for each probe packet it sends. It continues sending probe packets until a packet reaches the destination or until the `ttl` reaches the maximum number of hops.

In response to each probe packet, `traceroute` can receive one of the following ICMP messages:

- `time exceeded`
The IP router that received the probe packet cannot forward it any further due to the `ttl` value. This message tells you which IP routers are processing the packets.
- `port unreachable`
The probe packet reached its intended destination, but could not access the intended port.

When `traceroute` sends three probe packets (datagrams) for each `ttl` setting, it displays a line showing the following:

- `ttl`
- IP address of the host or router that responded
- Round-trip time of each probe datagram/ICMP response

If multiple IP routers respond to the probe, the `traceroute` command displays the address of each IP router. If the `traceroute` command does not elicit a response in 3 seconds (the default wait time), an asterisk (*) is displayed for the probe.

The following example shows a successful `traceroute` command to `host2`:

```
% traceroute host2
traceroute to host2 (555.55.5.5), 30 hops max, 40 byte packets
 1 host3 (555.55.5.1) 2 ms 2 ms 2 ms
 2 host5 (555.55.5.2) 5 ms 6 ms 4 ms
 3 host7 (555.55.5.3) 7 ms 7 ms 6 ms
 4 host2 (555.55.5.5) 12 ms 8 ms 8 ms
```

The `traceroute` command with the `host` argument prints the route that packets take to both IPv4 and IPv6 hosts.

See `traceroute(8)` for more information about this command and its options.

16.6 Displaying Headers of Packets on the Network

You display packet headers on the network when you want to monitor the network traffic associated with a particular network service. This is usually done to determine whether requests are being received or acknowledged, or to determine the source of network requests, in the case of slow network performance.

Use the `tcpdump` command to display packet headers for a network interface. This command enables you to specify the interface on which to listen, the direction of the packet transfer, and the type of protocol traffic to display. In addition, it enables you to identify the source of the packet. See `tcpdump(8)` for more information.

Note

In order to use the `tcpdump` command, the `packetfilter` option must be configured into the kernel and the system rebooted. See `packetfilter(7)` for more information.

16.7 Testing a UUCP Remote Connection

Testing a `uucp` remote connection can help you diagnose certain UUCP problems; for example, to determine why there is a backlog of transfer requests in the queue.

To test a remote connection, do the following:

1. Log in as root.
2. Change to the `/usr/lib/uucp` directory by using the `cd` command.
3. Test the remote connection by using the `uutry` command, using the following syntax:

```
uutry system_name
```

The *system_name* variable names the remote system to contact.

4. Examine the debugging output; the last line contains the status of the transaction. If your local system establishes a connection to the remote system, the debugging output contains a good deal of information. You can press Ctrl/C to stop the `uutry` shell script.

The `uutry` command has the following characteristics:

- It is a shell script stored in the `/usr/lib/uucp` directory.
- It contacts a remote system with debugging turned on. If you are using the UUCP scheduler, `uusched`, to start `uucico` automatically at specified intervals, the `uutry` command overrides the retry time interval specified in the `/usr/spool/uucp/.Status/system_name` file.

If you use the `uutry` command frequently, you can put the pathname to the command in the `PATH` entry in your `.profile` file.

- It directs debugging information to a file named `/tmp/system_name`, where *system_name* is the name of the local system. The `uutry` command then executes a `tail -f` command to display the file's contents.

If your local system cannot contact the remote system, do the following:

1. Validate the physical connections between the local and remote systems. At both systems, confirm that the computer is turned on, that all the cables are properly connected, that the ports are enabled, and the modems (if being used) are working. If the remote system is not at your physical location, contact the administrator of the remote system.
2. Verify all configuration files on both systems. Verify that all entries in the `Devices`, `Systems`, and `Permissions` files are correct. If you are using a modem, verify all entries in the `Dialers` and `Dialcodes` files.

If you are using a TCP/IP connection, verify that the configuration files contain the correct TCP entries. Verify that the `inetd` daemon can start the `uucpd` daemon. Edit the `/etc/inetd.conf` file and delete the comment character (`#`) from the beginning of the line containing the `uucp` entry. Restart the `inetd` daemon by using the following command:

```
# /sbin/init.d/inetd start
```

Always save the debugging output produced by the `uutry` command until you are certain that the problem is resolved.

The following example shows a successful test of a remote connection to system `host6`:

```
# /usr/lib/uucp/uutry host6
:
```

```
Conversation Complete: Status SUCCEEDED
```

The following example shows an unsuccessful test of a remote connection to system host6:

```
# /usr/lib/uucp/uutry host6
:
mchFind called (host6)
conn (host6)
getto ret -1
Call Failed: CAN'T ACCESS DEVICE
exit code 101
Conversation Complete: Status FAILED
```

16.8 Monitoring a UUCP File Transfer

Monitoring a uucp file transfer enables you to diagnose other UUCP problems, especially if you can already establish a remote UUCP connection.

To monitor a file transfer, do the following:

1. Verify the status of the files in the spooling directory on your local system by using the `uustat -q` command.
2. Verify that the local system can contact the remote system by using the `uutry system_name` command.
3. If the debugging output indicates that the connection was not successful, follow the steps described in Section 16.7 to test the remote connection..
4. Prepare a file for transfer by using the `uucp -r` command. The `-r` option instructs uucp to place the file in the queue without starting the uucico daemon.

Start the file transfer by using the `uutry` command.

See `uutry(1)` for additional information on this command.

The following example sends the test1 file to the system host6:

```
# uucp -r test1 host6! ~/test1
# /usr/lib/uucp/uutry host6
```

16.9 Viewing the Error Log File

To diagnose kernel and hardware errors, you can look at the system events that occurred prior to the errors. Messages from system events, such as error messages relating to the software kernel and system hardware, and informational messages about system status, startup, and diagnostics, are recorded in the binary error log file, `/var/adm/binary.errlog`.

Because this log file is in binary format, the operating system offers special utilities, DECEvent and Compaq Analyze, that read the binary log file and run the data through a formatter to display the information. See `dia(8)` and `ca(8)` for more information about DECEvent and Compaq Analyze, respectively.

Note that these utilities are not available in the operating system by default; you must install the Web-Based Enterprise Services (WEBES) kit, a suite of diagnostic utilities, to obtain them. WEBES is available for installation from the Associated Product CD-ROMs or for download from the following URL:

<http://www.support.compaq.com/svctools/webes>

See the *System Administration* guide for information about using the Event Viewer to present errors as interpreted by DECEvent and Compaq Analyze. Also, see `uerf(8)` for an alternative to these utilities.

16.10 Viewing the syslogd Daemon Message Files

You can use the `syslogd` daemon to help diagnose session layer problems such as access control problems for the Internet Protocol Version 4 (IPv4) and Internet Protocol Version 6 (IPv6).

The `syslogd` daemon starts running when you boot the system and whenever it receives a hangup signal. By default, it records the system messages for these events in a set of files in the `/var/adm/syslog.dated` directory (as specified in the `/etc/syslog.conf` file). The system messages can indicate error conditions or warnings, depending on the priority codes they contain.

Although it is possible to review the contents of the system message files from the command line, it is best to use the Event Viewer that is part of the SysMan Menu utility, because it simplifies access to the files and makes it easier for you to find particular problems. To start the Event Viewer, invoke the SysMan Menu as described in Section 1.1.1, then select Monitoring and Tuning→View events. Alternatively, you can invoke the Event Viewer from a command line by entering the following command:

```
# /usr/bin/sysman event_viewer
```

Once the Event Viewer is displayed, you can use it to sort the log entries, filter the entries (for a certain event name, priority level, posting host, or date), and obtain more detailed information about individual entries.

For more information about event management and accessing the system log files, see `evm(5)`, `syslogd(8)`, the *System Administration* guide, and the online help.

Testing DNS Servers

In concept, testing DNS/BIND servers consists of locating the information you need. In practice, testing DNS servers involves tracing through a network of servers and their databases to find the server responsible for the information. This section describes the tests you can use to locate the information.

17.1 Glossary

The following terms are used in this section. Refer to them as needed during the problem solving tests.

authoritative server

A server that stores information locally. Master and slave servers are examples of authoritative servers. They have primary and secondary authority, respectively, for a given domain.

In contrast, a server that is not authoritative must ask other servers for information about the target host. A forward-only server is an example of this type of server because it forwards queries to a list of forwarders that can answer such requests.

current server

The server you are currently logged in to and running tests from.

data types

The types of resource records in the DNS database files. See `named(8)` for a complete list and explanation.

forwarder

A server that can answer DNS queries from data in its databases and cache, whether or not it is authoritative for the information. Forwarder entries can be in the `named.conf` file.

nameserver (NS) record

Nameserver records map a domain name to a system that serves the domain, and determine whether a system is familiar with the name servers for the authoritative domain. Nameserver records have the following form:

```
domain-name           IN      NS      machine-name
```

On the left is the domain name; on the right is the name of the machine that services the domain.

master server

A server that stores the main copy of a target domain's databases. A master server has primary authority for name service information in a given domain.

slave server

A server that pulls a copy of the target domain's data from another server. In most cases, the data is pulled from a master server. However, in some cases, the data is pulled from another slave server.

A slave server has secondary authority for name service information in a given domain.

start of authority (SOA) record

Start of authority records mark the start of a zone of authority. They occur at the beginning of each master database file. SOA records have the following form:

domain-name IN SOA *machine-name*

target domain name

The portion of the target host name that begins after the first period (.).

target host

The host name you are trying to resolve. The target domain name is derived from the target host name.

17.2 DNS Server Testing Worksheet

Figure 17–1 shows the DNS Server Testing Worksheet, which you can use to record information from the tests in the following sections. If you are viewing this manual online, you can use the print feature of your browser to print a copy of this worksheet. On a copy of the worksheet, write the current server's name, current domain name, and target domain name.

Figure 17–1: DNS Server Testing Worksheet

DNS SERVER TESTING WORKSHEET			Sheet <input style="width: 20px;" type="text"/> of <input style="width: 20px;" type="text"/>
Current server:			
Server type:

			Yes <input type="checkbox"/> No <input type="checkbox"/>
			Yes <input type="checkbox"/> No <input type="checkbox"/>
			Yes <input type="checkbox"/> No <input type="checkbox"/>

17.3 Starting the DNS Server Test

To determine if the current server can resolve the target data, complete the following steps:

1. Determine whether the current server can access the target data. Use the following commands:

```
# nslookup
Default Server: host1.corp.com
Address: 127.0.0.1

> server localhost
Default Server: localhost.corp.com
Address: 127.0.0.1

> set timeout=45
> set retry=2
> target_host.target_domain.
```

If the nslookup command:	Action:
Succeeds	Go to step 3.
Fails	If the first time, go to step 2. If the second time, go to Section 17.4.

- Determine whether the `named` daemon is running by using the following command:

```
# ps gax | grep named
```

If the named daemon is:	Action:
Running	Go to step 1.
Not running	Start the daemon by using the <code>/sbin/init.d/named start</code> command. If the Internet name service started message is displayed, go to step 1. If the message is not displayed, this machine is not configured as a DNS server. Decide how the machine is to be configured. See Section 8.5 for more information.

- Log in to the client system and use the `nslookup` command to try to access the target data.

If the <code>nslookup</code> command:	Action:
Succeeds	STOP. The client can resolve the target data.
Fails	The server knows the information, but is not transferring it to the client. Log out from the client; restart DNS on the server by using the <code>/sbin/init.d/named restart</code> command; log in to the client; and use the <code>nslookup</code> command. If it cannot resolve the target data, you have the wrong server or the DNS server is malfunctioning.

17.4 Determining the Server Type

To determine whether the current server is a master server or a slave server, complete the following steps:

1. Compare the target domain name with all domain names of the master and slave entries in the `/etc/named.conf` file. These entries have the following form:

```
zone "domain" {      type server-type;      file
"filename.db"; };
```

The following example shows the `zz.bb.cc.` target domain and subsets of this target domain:

```
# cat /etc/named.conf
:
options {
    directory "/etc/namedb";
};

zone "aa.bb.cc" {      ❶
    type master;
    file "aa.bb.cc.db";
};

zone "cc" {           ❷
    type master;
    file "cc.db";
};

zone "bb.cc" {       ❸
    type slave;
    file "bb.cc.db";
    masters {
        128.102.0.42;
    };
};
```

```

zone "zz.bb.cc" { 4
    type slave;
    file "zz.bb.cc.db";
    masters {
        128.102.29.73;
    };
};
:

```

- 1 This zone entry is not a subset of the `zz.bb.cc` domain.
- 2 This zone entry is a subset of the `zz.bb.cc` domain. The server is a master server for the `cc` domain and it stores the information for this domain in the `cc.db` file.
- 3 This zone entry is a subset of the `zz.bb.cc` domain. The server is a slave server for the `bb.cc` domain and it stores the information for this domain in the `bb.cc.db` file.
- 4 This zone entry matches the `zz.bb.cc` domain. The server is a slave server for the `zz.bb.cc` domain and it stores the information for this domain in the `zz.bb.cc.db` file.

For more information on the format of the `named.conf` file, see `named.conf(8)` and the *BIND Configuration File Guide*.

When directed, record information in the `named.conf` file section on the worksheet.

If a <code>named.conf</code> entry:	And the type is:	Action:
Matches the target domain name	Master	Write the server type, domain name, and database file name on the worksheet and go to Section 17.8.
	Slave	Write the server type, domain name, database file name, and host IP addresses on the worksheet and go to Section 17.7.
Is a subset of the target domain name	Master	Write the server type, domain name, and database file name on the worksheet and go to step 2.
	Slave	Write the server type, domain name, database file name, and host IP addresses on the worksheet and go to step 2.
Neither matches nor is a subset of the target domain name	Master or slave	Go to Section 17.5.

- Compare the target domain name with all nameserver (NS) records in the database file recorded on the worksheet. When directed, record information in the Nameservers section on the worksheet. Use the following commands to create and view a list of NS records:

```
# grep -n NS database_file > ns_list
# grep -n ORIGIN database_file >> ns_list
# sort -n ns_list > ns_list.srt
# cat ns_list.srt
```

The following example shows the file created by these commands. The target domain is zz.bb.cc.:

```
# cat ns_list.srt
1:$ORIGIN cc.
10:                IN          NS           server_1.cc.
17:$ORIGIN cc.
18:bb              IN          NS           server_3.bb.cc.
21:$ORIGIN cc.
22:bb              IN          NS           server_4.bb.cc.
41:$ORIGIN bb.cc.
42:zz              IN          NS           server_5.zz.bb.cc. 1
45:$ORIGIN bb.cc.
46:zz              IN          NS           server_6.bb.cc. 2
```

- This entry is a longer subset (exact match) of the target domain. The domain name from the preceding \$ORIGIN line, .bb.cc., is appended to the domain name of this line, zz, resulting in zz.bb.cc..
- This entry is a longer subset (exact match) of the target domain. The domain name from the preceding \$ORIGIN line, .bb.cc., is appended to the domain name of this line zz, resulting in zz.bb.cc..

If any NS record:	And the server is:	Action:
Contains a longer subset of the target domain name than the domain name on the worksheet	Master or slave	The server has neither primary nor secondary authority for the target information. Write the names of the servers on the worksheet and go to step 3.
Does not contain a longer subset of the target domain name than the domain name on the worksheet	Master	The database files contain the target information. Go to Section 17.8.
	Slave	The database files contain the target information. Go to Section 17.7.

- Find the IP addresses in the database file for any name servers on the worksheet. Use the following commands:

```
# grep -n ORIGIN database_file > ip_list
# grep -n server_name database_file >> ip_list
:
# sort -n ip_list > ip_list.srt
# cat ip_list.srt
```

Write the IP addresses on the worksheet next to the corresponding server name and go to Section 17.5. The following example shows the file created by the preceding commands:

```
# cat ip_list.srt
1:$ORIGIN cc.
17:$ORIGIN cc.
21:$ORIGIN cc.
41:$ORIGIN bb.cc.
42:zz          IN          NS          server_5.zz.bb.cc.
43:$ORIGIN zz.bb.cc.
44:server_5    IN          A           10.140.48.3    ❶
45:$ORIGIN bb.cc.
46:zz          IN          NS          server_6.bb.cc.
47:$ORIGIN bb.cc.
48:server_6    IN          A           10.12.48.3    ❷
```

❶ The IP address for server_5 is 10.140.48.3.

❷ The IP address for server_6 is 10.12.48.3.

17.5 Finding the Target Domain Information

To determine the servers that the current server communicates with in order to get information for the target domain, complete the following steps:

1. Search the `named.conf` file and find any forwarder entries. These entries have the following form:

```
options {
    directory "directory-name";
    forward only;
    forwarders {
        IP-address;
        IP-address;
    };
};
```

When directed, record information in the Forwarders section on the worksheet.

If your system:	Action:
Contains a forwarder line	The current server forwards requests. Write the IP addresses for any forwarders on the worksheet and go to Section 17.6.
Does not contain a forwarder line	The current server does not forward queries. Go to step 2.

2. Compare the target domain name with all nameserver (NS) records in the database file recorded on the worksheet. When directed, record information in the Nameserver section on the worksheet.

Use the following commands to create and view a list of NS records for each database file:

```
# grep -n NS database_file > ns_list
# grep -n ORIGIN database_file >> ns_list
# sort -n ns_list > ns_list.srt
# cat ns_list.srt
```

If any NS record:	And:	Action:
Contains a longer subset of the target domain name than the domain name on the worksheet	→	Write the names of the servers on the worksheet and go to step 3.
Does not contain a longer subset of the target domain name than the domain name on the worksheet	The Nameserver section on the worksheet is blank	Go to Section 17.9.

3. Find the IP addresses in the database file for any name servers on the worksheet. Use the following commands:

```
# grep -n ORIGIN database_file > ip_list
# grep -n server_name database_file >> ip_list
:
# sort -n ip_list > ip_list.srt
# cat ip_list.srt
```

Write the IP addresses on the worksheet next to the corresponding server name and go to step 4.

4. Verify whether each server listed in the Nameserver section on the worksheet is reachable by using the `ping` command.

If a server:	And:	Action:
Responds to the <code>ping</code> command	You have root access to the server	The server is reachable and under your administrative control. Note both items on the worksheet. Go to step 5.
	You do not have root access to the server	The server is reachable, but not under your administrative control. Note both items on the worksheet. Go to step 5.
Does not respond to the <code>ping</code> command	→	Note this on the worksheet.
		If no servers responded to the <code>ping</code> command, STOP. The current server is isolated from its servers on the network. You cannot solve the problem; contact your enterprise network administrator.

5. Log in to each reachable server by using the `telnet` command. Each server you log in to becomes the current server. Get a new worksheet and write the current server name, current domain name, and target domain name on it. For each server, perform the DNS server test. See Section 17.3.

17.6 Testing the Forwarders

To determine whether the forwarders prevent you from resolving the target host name, complete the following steps:

1. Determine whether each forwarder listed on the worksheet is reachable by using the `ping` command.

If a forwarder:	And:	Action:
Responds to the <code>ping</code> command	You have root access to the forwarder	The forwarder is reachable and under your administrative control. Note both items on the worksheet. Go to step 2.
	You do not have root access to the forwarder	The forwarder is reachable, but not under your administrative control. Note both items on the worksheet. Go to step 2.

If a forwarder:	And:	Action:
Does not respond to the ping command	→	Note this on the worksheet. If no forwarders responded to the ping command, STOP. The current server is isolated from its forwarders on the network. You cannot solve the problem; contact your enterprise network administrator.

2. Edit the `named.conf` file and eliminate any forwarders that did not respond to the ping command.
3. Enter the `nslookup` command again for the target host.

If the nslookup command:	Action:
Succeeds	Go to step 4.
Fails	Go to step 5.

4. Edit the `named.conf` file and add the forwarders removed in step 2 at the end of the forwarders line. In addition, contact the administrators of forwarders not under your administrative control and inform them that they might have a problem with their forwarder. STOP.
5. Log in to each reachable forwarder by using the `telnet` command. This forwarder is now the current server. On a new worksheet, write the current server name, current domain name, and target domain name. For each server, perform the DNS server test. See Section 17.3.

If the forwarder or other machines:	Action:
Cannot resolve the target name	Remove the forwarder from <code>named.conf</code> file.
Can resolve the target name	STOP.

17.7 Testing Slave Servers

To determine whether the slave server contains the target data, complete the following steps:

1. Find the database serial number in the start of authority record in the database file. Use the following command:

```
# head -4 database_file
```

Write the first number, which is the serial number, on the worksheet in the `named.conf` section. If you have a serial number on a previous worksheet, compare the current serial number with that one. Note whether the current number is larger (newer) or smaller (older) than the other number. In the following example, 23 is the serial number:

```
# head -4 database_file
$ORIGIN cc.
bb      IN      SOA      host1.bb.cc. postmaster.host1.bb.cc. (
        23 300 60 1209600 43200 )
        IN      MX      100 host1.bb.cc.
```

2. Determine whether the target data is contained in the database file written on the worksheet. Use the following commands to create and view a list of resource records:

```
# grep -n data_type database_file > ns_list
# grep -n ORIGIN database_file >> ns_list
# sort -n ns_list > ns_list.srt
# cat ns_list.srt
```

If the database file:	And the serial number is:	Action:
Contains the target data	Newer	The data exists in the domain. Go to step 3.
Contains the target data	Older or same	The server is malfunctioning or you made a error. Verify all steps up to this point.
Does not contain the target data →		The data does not exist in the domain. Go to step 4.

3. Determine whether the current server can access the target data. Use the following commands:

```
# nslookup
Default Server: host1.corp.com
Address: 127.0.0.1

> server localhost
Default Server: localhost.corp.com
Address: 127.0.0.1

> set timeout=45
> set retry=2
> target_host.target_domain.
```

If the nslookup command:	And the database serial number is:	Action:
Succeeds	→	STOP. The server is working. Either the client or server cannot communicate with the server or this server just started working.
Succeeds	Newer	Log out of the slave server. Get the previous slave server's worksheet and go to step 8.
Fails	→	Restart the current slave server by using the <code>/sbin/init.d/named restart</code> command. Then reenter the <code>nslookup</code> command

4. Verify whether each name server listed on the worksheet is reachable by using the `ping` command.

If a server:	And:	Action:
Responds to the <code>ping</code> command	You have root access to the server	The server is reachable and under your administrative control. Note both items on the worksheet.
	You do not have root access to the server	The server is reachable, but not under your administrative control. Note both items on the worksheet.
Does not respond to the <code>ping</code> command	→	Note this on the worksheet. If no servers responded to the <code>ping</code> command, STOP. The current server is isolated from its servers on the network. You cannot solve the problem; contact your enterprise network administrator.

Count the number of servers that responded to the `ping` command and that are under your administrative control. If the number is zero (0), go to Section 17.10.

5. Edit the `named.conf` file and find the `slave` entry. Delete the IP address for those servers that are not reachable and are not under your administrative control. Delete those entries from the worksheet as well.
6. Log in to each reachable server by using the `telnet` command. Start a new worksheet for each server, writing the server name as the current server. Save the old worksheet.
7. Compare the target domain name with all domain names of the master and slave entries in the `/etc/named.conf` file. These entries have the following form:

```
zone "domain" {
    type server-type;
    file "filename.db";
};
```

When directed, record information in the `named.conf` file section on the worksheet.

If a <code>named.conf</code> entry:	And the first field is:	Action:
Matches the target domain name	Master	Write the domain name and database file name on the worksheet and go to Section 17.8.
	Slave	Write the domain name, host IP addresses, and the database file name on the worksheet and go to step 1.
Is a subset of the target domain name	→	STOP. Examine another master or slave server entry.
Neither matches nor is a subset of the target domain name	→	STOP. Examine the next master or slave server entry.

8. Restart the current slave server by using the following command:

```
# /sbin/init.d/named restart
```

After restarting, wait a few minutes before proceeding to the next step. This allows time for the database to be updated.

9. Determine whether the current server can access the target data. Use the following commands:

```
# nslookup
Default Server: host1.corp.com
Address: 127.0.0.1

> server localhost
```

```
Default Server: localhost.corp.com
Address: 127.0.0.1
```

```
> set timeout=45
> set retry=2
> target_host.target_domain.
```

If the nslookup command: Action:

Succeeds	STOP. The server is working. If you are in a telnet session to another slave server, log out and go to step 8.
FAILS	If you just ended a telnet session to another server, go to step 10. If you did not end a telnet session, either the current server is malfunctioning and cannot read the database file or you made an error. Verify all steps up to this point.

10. Compare the database serial number of the current server with the database serial number of the server from which you just logged out. Use the following command:

```
# head -4 database_file
```

If the current database serial number is: Action:

Older	Either the server cannot pull the database from the authoritative server or you made an error. Verify all steps up to this point.
The same	The serial numbers cannot be equal. Verify all steps up to this point.

17.8 Testing Master Servers

To determine whether the master server contains the target data, complete the following steps:

1. If you are in a telnet session from a slave server to a master server, go to step 2. Otherwise, go to step 3.
2. Find the database serial number in the start of authority record in the database file. Use the following command:

```
# head -4 database_file
```

Write the first number, which is the serial number, on the worksheet in the `named.conf` section. If you have a serial number on a previous worksheet, compare the current serial number with that one. Note

whether the current number is larger (newer) or smaller (older) than the other number. In the following example, 23 is the serial number:

```
# head -4 database_file
$ORIGIN cc.
bb      IN      SOA      host1.bb.cc. postmaster.host1.bb.cc. (
      23 300 60 1209600 43200 )
      IN      MX      100 host1.bb.cc.
```

- Determine whether the target data is contained in the database file written on the worksheet. Use the following commands to create and view a list of resource records:

```
# grep -n data_type database_file > ns_list
# grep -n ORIGIN database_file >> ns_list
# sort -n ns_list > ns_list.srt
# cat ns_list.srt
```

If the database file:	Action:
Contains the target data	The data exists in the domain. Go to step 4.
Does not contain the target data	The data does not exist in the domain. Go to step 5.

- Determine whether the current server can access the target data. Use the following commands:

```
# nslookup
Default Server: host1.corp.com
Address: 127.0.0.1

> server localhost
Default Server: localhost.corp.com
Address: 127.0.0.1

> set timeout=45
> set retry=2
> target_host.target_domain.
```

If the nslookup command:	And the database serial number is:	Action:
Succeeds	→	STOP. The server is working. Either the last server cannot communicate with this server or this server just started working.
Succeeds	Older or same	STOP. The server is malfunctioning or you made an error. Verify all steps up to this point.

If the <code>nslookup</code> command:	And the database serial number is:	Action:
Succeeds	Newer	Log out of the master server. Get the previous slave server's worksheet and go to step 8 in Section 17.7.
Fails	→	Restart the current master server by using the <code>/sbin/init.d/named restart</code> command. Then reenter the <code>nslookup</code> command.

5. Edit the database file and increment the database serial number by 1 to age the database. The following example shows the SOA record before and after editing. Note the serial number increase from 23 to 24.

```
# head -4 database_file
$ORIGIN cc.
bb      IN      SOA      host1.bb.cc. postmaster.host1.bb.cc. (
        23 300 60 1209600 43200 )
        IN      MX      100 host1.bb.cc.
# vi database_file
:
:
# head -4 database_file
$ORIGIN cc.
bb      IN      SOA      host1.bb.cc. postmaster.host1.bb.cc. (
        24 300 60 1209600 43200 )
        IN      MX      100 host1.bb.cc.
```

6. Edit the database file and add new data to the database. Refer to Section 17.1 for information on valid data types. Precede any new entry with a `$ORIGIN` entry, and separate database fields with a tab character. The following example shows a new address record for host `host1.bb.cc.`:

```
$ORIGIN bb.cc
host1      IN      A      16.141.112.11
```

7. Restart the master server by using the following command:

```
# /sbin/init.d/named restart
```

8. Determine whether the current server can access the target data. Use the following commands:

```
# nslookup
Default Server: host1.corp.com
Address: 127.0.0.1

> server localhost
Default Server: localhost.corp.com
Address: 127.0.0.1

> set timeout=45
> set retry=2
> target_host.target_domain.
```

If the <code>nslookup</code> command:	Action:
Succeeds	Log out of the master server. Get the previous slave server's worksheet and go to step 8 in Section 17.7.
Fails	Either the server is malfunctioning or you made an error. Verify all steps up to this point.

17.9 Tracing Information from the Root Name Server

To resolve the target name beginning with the root of the DNS namespace, complete the following steps:

1. Determine whether the current server has a cache file containing the information necessary to find a root server. Use the following command:

```
# grep cache /etc/named.conf
```

If a cache line:	Action:
Does not exist	The current server cannot contact a root name server. Note this on the worksheet and go to step 2.
Exists	Note this on the worksheet and go to step 3.

2. Add a cache file to your server.

Caution

Adding a cache file alters many system files. Perform the following steps as shown to ensure the correct operation of your system.

- a. Create copies of specific DNS and system files. Enter the following commands:

```
# cd /etc
# cp -r namedb namedb.back
# cp rc.config.common rc.config.common.back
# cp hosts hosts.back
# cp resolv.conf resolv.conf.back
# cp svc.conf svc.conf.back
# cd /var/adm/sendmail
# cp sendmail.cf sendmail.cf.back
```

- b. Display the name of the local host by using the `hostname` command. You will need to reset the host name after running the SysMan Menu utility and copying system files.

- c. Run the SysMan Menu utility. Modify the configuration and create a caching server (see Section 8.5.3). Do not start the DNS daemon automatically and do not run `svcsetup`.
- d. Copy the system files to the `/etc` directory. Use the following commands:

```
# cd /etc
# cp rc.config.common.back rc.config.common
# cp hosts.back hosts
# cp resolv.conf.back resolv.conf
# cp svc.conf.back svc.conf
```

- e. Set the host name to the original host name by using the `hostname` command.
- f. Copy the `sendmail` file to the `/var/adm/sendmail` directory and restart `sendmail`. Use the following commands:

```
# cd /var/adm/sendmail
# cp sendmail.cf.back sendmail.cf
# /sbin/init.d/sendmail restart
```

- g. Copy the DNS files to the `/etc` directory. Use the following commands:

```
# cd /etc
# cp namedb/namedb.boot namedb.back/named.conf_new
# cp namedb/namedb.ca namedb.back
# rm -rf namedb.back namedb
# mv namedb.back namedb
# cd namedb
```

- h. Edit the `named.conf` file and add the following lines to the end of the file:

```
zone "." {
    type hint;
    file "named.ca";
};
```

- i. Remove the `named.conf_new` file.
- j. Restart the current server by using the `/sbin/init.d/named restart` command.

3. Display the `named.ca` file by using the following command:

```
# cat named.ca
```

Write the root name server names and IP addresses in the Root nameservers section on the worksheet.

4. Verify whether each root name server listed on the worksheet is reachable by using the `ping` command.

If a root name server:	Action:
Responds to the <code>ping</code> command	Note this on the worksheet. Go to Section 17.11.
Does not respond to the <code>ping</code> command	Note this on the worksheet. If no servers responded to the <code>ping</code> command, go to step 5.

5. Do either of the following:

- Give the current server access to the Internet. Then restart the `named` daemon by using the following command:

```
# /sbin/init.d/named restart
```

Keep the current server and worksheet, and go to Section 17.3.

- Add a forwarder entry to direct the current server to communicate with a machine with Internet access. Then restart the `named` daemon by using the following command:

```
# /sbin/init.d/named restart
```

Keep the current server and worksheet, and go to Section 17.3.

17.10 Resolving Target Data

To resolve target data using a name server, complete the following steps:

1. Enter the `nslookup` command for the target system. Choose the first name server from either the Root nameserver section or the Nameserver section. Use the following commands:

```
current_server> nslookup
Default Server: localhost.omni.corp.com
Address: 127.0.0.1
```

```
> server IP_address
Default Server: [IP_address]
Address: 128.102.16.10
```

```
> set type data_type
> target_name
```

If the nslookup command:	And:	Action:
Succeeds	→	STOP. The server is working. Either the last server you tested does not talk to this one or this server just started working. Verify all steps completed up to this point.
Fails	An error message is returned.	<p>If a “non-existent domain” message is displayed, no data exists for the <i>target_name</i>. Go to Section 17.11.</p> <p>If a “no information available” message is displayed, the <i>target_name</i> exists, but is not associated with the target data. If the data is required, contact the target domain administrator and request that the data be added to the domain.</p> <p>If a “timed-out” message is displayed, the server to which you sent the query cannot contact the server that is responsible for the target data. Go to step 2.</p>
Fails	An error message is not returned.	An unknown error. Contact the target domain administrator.

2. Modify the retry and timeout values and re-enter the nslookup command. Enter the following commands:

```

current_server> nslookup
Default Server: localhost.omni.corp.com
Address: 127.0.0.1

> server IP_address
Default Server: [IP_address]
Address: IP_address

> set type data_type
> target_name

```

If the <code>nslookup</code> command:	And:	Action:
Succeeds	→	STOP. The server is working, but is slow. This might prevent the query from being resolved. If the network connection to the server is correct, wait two or three hours for the performance to improve. If it does not improve, contact the server administrator.
Fails	An error message is returned	<p>If a “non-existent domain” message is displayed, no data exists for the <i>target_name</i>. Go to Section 17.11.</p> <p>If a “no information available” message is displayed, the <i>target_name</i> exists, but the target data is not associated with it. If the data is required, contact the target domain administrator and request that the data be added to the domain.</p> <p>If a “timed-out” message is displayed, the server to which you sent the query cannot access the server that is responsible for the data. Select another nameserver from the worksheet and go to step 1.</p>
Fails	An error message is not returned	An unknown error. Contact the target domain administrator.

17.11 Finding the First Nonexistent Domain

To find the first nonexistent domain in a target name, complete the following steps:

1. Enter the `nslookup` command, using the smallest subset of the target domain name. Enter the following commands:

```
current_server> nslookup
Default Server: localhost.omni.corp.com
Address: 127.0.0.1

> server IP_address
Default Server: [IP_address]
Address: IP_address

> set type=ns
> target_name_subset
```

For example, if the target domain name is `zz.bb.cc.`, the first attempt is to resolve the target name subset `cc.`. If necessary, the second attempt uses `bb.cc.`, and the third, `zz.bb.cc.`.

If the <code>nslookup</code> command:	And:	Action:
Succeeds	→	Go to step 3.
Fails	An error message is returned	If a “non-existent domain” message is displayed, no data exists for the <code>target_name</code> . If the data is required, contact the domain administrator and request that the data be added to the domain. STOP. If a “timed-out” message is displayed, go to step 2.

2. Modify the retry and timeout values and enter the `nslookup` command again. Enter the following commands:

```
current_server> nslookup
Default Server: localhost.omni.corp.com
Address: 127.0.0.1

> server IP_address
Default Server: [IP_address]
Address: IP_address

> set retry=2
> set timeout=45
> set type=ns
> target_name_subset
```

If the <code>nslookup</code> command:	And:	Action:
Succeeds	→	Go to step 3.
Fails	An error message is returned	If a “non-existent domain” message is displayed, no data exists for the <code>target_name</code> . If the data should exist, contact the domain administrator and request that the data be added to the domain. STOP. If a “timed-out” message is displayed, select another name server from the worksheet and go to Section 17.10.

3. Add the next part of the target domain name to the target subset and go to step 1.

Reporting Network Problems

If you are unable to solve a critical problem with the network or network service, do the following:

1. Read the release notes for the product to see if the problem is known. If it is, follow the solution offered to solve the problem.
2. Determine whether the product is still under warranty or whether your company purchased support services for the product. Your operations manager can supply you with the necessary information.
3. If either condition in step 2 was met, take one of the following actions:
 - a. Access the online service database, if you have purchased this service, and determine if the problem you are experiencing has already been reported. If it has not, log your problem.
 - b. Call your service representative and describe the problem.
4. If you are requested to supply any information pertaining to the problem, gather the necessary information and submit it.

18.1 Gathering Information

You might be asked to submit some information that can help isolate problems to a particular area of the system and speed the resolution of the problem. It is a good idea to keep all basic information in a `system.information` file. Then you can easily include it with your problem report.

The following sections describe some of the information that you might be asked to submit.

18.1.1 General Information

Gather the following information about your system:

- The operating system version and revision number (from the `/etc/motd` file). Add this to the `system.information` file.
- A description of your system's activity before the error.
- A listing of the exact command line or lines executed and the output.

- A copy of the application source code, if running a user-created application. If possible, include a sample test program that demonstrates the problem.

18.1.2 Hardware Architecture

Gather the following information about the hardware architecture:

- A description of the model of the workstation or server (from the `/usr/sys/conf/HOSTNAME` file), including the type of graphics controller (if a workstation), the amount of memory, and third-party hardware

- A description of the X server

To determine which type you are running, enter the following command:

```
# ps ax | grep /usr/bin/X >> system.information
```

- A description of the disks used and the size of your swap partition

For example, if your system disk is unit 0, enter the following commands as root to add this information to the `system.information` file:

```
# disklabel -r /dev/rrz0a >> system.information
# echo df: >> /system.information
# df >> /system.information
# echo mount: >> /system.information
# mount >> /system.information
# echo xdpinfo: >> /system.information
# xdpinfo >> /system.information
```

- Any networking information

To add this to the `system.information` file, enter the following commands:

```
# echo netstat: >> /system.information
# netstat -i -n >> system.information
# netstat -r -n >> /system.information
# echo nslookup: >> /system.information
# nslookup localhost >> /system.information
```

- Any event logging information

To add this to the `system.information` file, enter the following commands:

```
# uerf -R -o full | head -200 >> /system.information
```

18.1.3 Software Architecture

Gather the following information about the software architecture:

- A description of the software subsets installed

To add this to the `system.information` file, enter the following commands:

```
# echo setld: >> /system.information
# setld -i >> /system.information
```

- The output of the `setld` log file

To add this to the `system.information` file, enter the following command:

```
# pr /usr/adm/smlogs/setld.log >> /system.information
```

- The automatic reboot file

To add this to the `system.information` file, enter the following commands:

```
# pr /etc/rc.config* >> /system.information
# pr /sbin/rc[023] >> /system.information
# pr /sbin/init.* >> /system.information
```

- A description of the layered products installed

A

Monitoring the Network Interfaces

The `netstat` command can help you monitor the Ethernet, Fiber Distributed Data Interface (FDDI), and token ring network interfaces. The following sections contain sample system output and a description of the information for each network interface.

A.1 Monitoring the Ethernet Interface

You can use the `netstat -I ln0 -s` command to obtain a listing of the Ethernet counters. The following is sample system output from this command:

```
ln0 Ethernet counters at Thu Nov 6 07:33:00 1992
    1289 seconds since last zeroed
16812469 bytes received
4657308 bytes sent
    42555 data blocks received
    28418 data blocks sent
860360 multicast bytes received
    7710 multicast blocks received
    546 multicast bytes sent
    13 multicast blocks sent
    0 blocks sent, initially deferred
    1864 blocks sent, single collision
    5542 blocks sent, multiple collisions
    6 send failures, reasons include:
        Excessive collisions
    0 collision detect check failure
    3 receive failures, reasons include:
        Block check error
        Framing Error
    0 unrecognized frame destination
    0 data overruns
    0 system buffer unavailable
    0 user buffer unavailable
```

The following section lists each field in the previous example alphabetically, and describes each field.

blocks sent, initially deferred

The number of times a frame transmission was deferred on its first transmission attempt. Used in measuring Ethernet contention with no collisions.

blocks sent, multiple collisions

The number of times a frame was successfully transmitted on the third or later attempt after normal collisions on previous attempts.

blocks sent, single collision

The number of times a frame was successfully transmitted on the second attempt after a normal collision on the first attempt.

bytes received

The number of bytes successfully received.

bytes sent

The number of bytes successfully transmitted.

collision detect check failure

The number of times a collision detection was not sensed after a transmission.

data blocks received

The number of frames successfully received.

data blocks sent

The number of frames successfully transmitted.

data overruns

The number of times a frame was discarded because no receive buffer was available.

multicast blocks received

The number of frames successfully received in multicast frames.

multicast blocks sent

The number of frames successfully transmitted in multicast frames.

multicast bytes received

The number of bytes successfully received in multicast frames.

multicast bytes sent

The number of bytes successfully transmitted in multicast frames.

receive failures, reasons include:

The number of times a receive error occurred. Each receive error is classified as one of the following:

- **Block check error**
- **Framing error**
- **Frame too long**

seconds since last zeroed

The number of seconds since the associated counter attributes were set to zero.

send failures, reasons include:

The number of times a transmit error occurred. Each transmit error is classified as one of the following:

- **Excessive collisions**
- **Carries check failed**
- **Short circuit**
- **Open circuit**
- **Frame too long**
- **Remote failure to defer**

system buffer unavailable

The number of times a frame was discarded because no link buffer was available.

unrecognized frame destination

The number of times a frame was discarded because there was no data link port. The count includes frames received for the physical address only. It does not include frames received for the multicast or broadcast address.

user buffer unavailable

The number of times a frame was discarded because no user buffer was available.

A.2 Monitoring the FDDI Interface

You can use the `netstat -I interface -s` command to obtain a listing of the Fiber Distributed Data Interface (FDDI) counters, status, and characteristics for the FDDI interface. The following is sample system output from this command for the `fza0` interface. See `faa(7)`, `fta(7)`, `fza(7)`, and `mfa(7)` for adapter error messages.

```
fza0 FDDI counters at Wed Jun 12 14:02:44 1992
      89 seconds since last zeroed
6440875 ANSI MAC frame count
      0 ANSI MAC frame error count
      0 ANSI MAC frames lost count
37488 bytes received
39005 bytes sent
  447 data blocks received
  479 data blocks sent
30170 multicast bytes received
  321 multicast blocks received
29163 multicast bytes sent
  360 multicast blocks sent
      0 transmit underrun errors
      0 send failures
      0 FCS check failures
      0 frame status errors
      0 frame alignment errors
      0 frame length errors
      0 unrecognized frames
      0 unrecognized multicast frames
      0 receive data overruns
      0 system buffers unavailable
      0 user buffers unavailable
      0 ring reinitialization received
      0 ring reinitialization initiated
      0 ring beacon process initiated
      0 ring beacon process received
      0 duplicate tokens detected
      0 duplicate address test failures
      0 ring purger errors
      0 bridge strip errors
      0 traces initiated
      0 traces received
      0 LEM reject count
      0 LEM events count
      0 LCT reject count
```

0 TNE expired reject count
1 completed connection count
0 elasticity buffer errors

fza0 FDDI status

Station State: On
Last Station ID: Not Implemented
Station UID: 00-00-08-00-2B-A2
Link State: On ring running
Link UID: 08-00-2B-A2-B5-84
Negotiated TRT: 7.987 ms
Duplicate Address Test: Absent
Upstream Neighbor Address: 08-00-2B-18-B3-D7
Old Upstream Neighbor Address: 08-00-2B-1E-C0-3E
Upstream Neighbor Dup Addr Flag: Unknown
Downstream Neighbor Address: 08-00-2B-1E-C0-3E
Old Downstream Neighbor Address: 08-00-2B-1E-C0-3E
Ring Purger State: Purger off
Frame Strip Mode: Source Address Match
Ring Error Reason: No reason
Loopback Mode: False
Ring Latency: 0.000 ms
Ring Purge Address: Not Implemented
Physical Port State: In use
Physical Port UID: 08-00-2B-A2-B5-84
Neighbor Physical Port Type: Master
Physical Link Error Estimate: 15
Broken Reason: None
Reject Reason: No reason

fza0 FDDI characteristics

Station ID: 00-00-08-00-2B-A2
Station Type: SAS
SMT Version ID: 2
SMT Max Version ID: 2
SMT Min Version ID: 2
Link Address: 08-00-2B-A2-B5-84
Requested TRT: 8.000 ms
Valid Transmission Time: 2.621 ms
Restricted Token Timeout: 1000.000 ms
Ring Purger Enable: FALSE
Physical Port Type: Slave
PMD Type: ANSI multimode
LEM Threshold: 8

The Downstream Neighbor Address and Restricted Token Timeout are reported only for the DEFZA firmware revision 1.2 and higher.

The following sections list each field in the previous example alphabetically, and describe each field.

A.2.1 FDDI Counters

This section lists the FDDI counters alphabetically.

ANSI MAC frame count

The total number of frames (other than the token frame) seen by this link.

ANSI MAC frame error count

The total number of times the media access control (MAC) changed the E indicator in a frame from R to S.

ANSI MAC frames lost count

The total number of times a frame (other than the token frame) was improperly terminated.

bridge strip errors

The number of times a frame content independent strip operation was terminated by receipt of a token.

bytes received

The number of bytes successfully received.

bytes sent

The number of bytes successfully transmitted.

completed connection count

The number of times the physical (PHY) port entered the In Use state, having completed the initialization process.

data blocks received

The number of frames successfully received.

data blocks sent

The number of frames successfully transmitted.

duplicate address test failures

The number of times the duplicate address test failed.

duplicate tokens detected

The number of times the MAC detected a duplicate token, either via the duplicate token detection algorithm or by receiving a token while already holding one.

elasticity buffer errors

The number of times the Elasticity Buffer function in the PHY port had an overflow or underflow.

FCS check failures

The number of times a received frame failed the Frame Control Status (FCS) check.

frame alignment errors

The number of times a received frame had an alignment error.

frame length errors

The number of times a received frame had an invalid length, either too long or too short.

frame status errors

The number of times a received frame had the E indicator in error but the cyclic redundancy check (CRC) was correct.

LCT reject count

The number of times a connection on this physical port was rejected due to failure of the link confidence test (LCT) at either end of the physical connection.

LEM events count

The number of errors detected by the link error monitor (LEM) on the physical layer.

LEM reject count

The number of times an active connection on this physical port was disconnected due to rejection by the LEM at this end of the physical connection.

multicast blocks received

The number of frames successfully received in multicast frames.

multicast blocks sent

The number of frames successfully transmitted in multicast frames.

multicast bytes received

The number of bytes successfully received in multicast frames.

multicast bytes sent

The number of bytes successfully transmitted in multicast frames.

receive data overruns

The number of times a frame was discarded because no receive buffer was available.

ring beacon process initiated

The number of times the ring beacon process was initiated by this link.

ring beacon process received

The number of times the ring beacon process reinitialization was initiated by some other link.

ring purger errors

The number of times the ring purger received a token while still in the ring purge state.

ring reinitialization initiated

The number of times a ring reinitialization was initiated by this link.

ring reinitialization received

The number of times a ring reinitialization was initiated by some other link.

seconds since last zeroed

The time at which the link entity was created. This value indicates when the associated counter attributes were set to zero.

send failures

The number of times a transmit error (other than transmit underrun) occurred.

system buffers unavailable

The number of times a frame was discarded because no link buffer was available.

TNE expired reject count

The number of times an active connection on this physical port was disconnected due to rejection by expiration of the noise timer (TNE).

traces initiated

The number of times the PC-trace process was initiated by this link.

traces received

The number of times the PC-trace process was initiated by some other link.

transmit underrun errors

The number of times a transmit underrun error occurred. This indicates the transmit first-in/first-out (FIFO) buffer became empty during frame transmission.

unrecognized frames

The number of times a received, individually addressed logical link control (LLC) frame was discarded because there was no data link port.

unrecognized multicast frames

The number of times a received LLC frame addressed to a multicast address was discarded because there was no data link port.

user buffers unavailable

The number of times a frame was discarded because no user buffer was available.

A.2.2 FDDI Status

This section lists the FDDI status alphabetically.

Broken Reason

The reason that the physical port is in the Broken state (for non-SAS stations). This field can have one of the following values:

Broken	The physical port is broken.
None	The physical port is not in the <code>Broken</code> state.

Downstream Neighbor Address

The 48-bit hardware address of the station that is on the downstream side of the ring from this station.

Duplicate Address Test

The result of the duplicate address test performed by the FDDI MAC entity of the station. This field can have one of the following conditions:

Absent	The FDDI MAC entity determined that there is no duplicate of its own line address on the ring.
Present	The FDDI MAC entity determined that a duplicate of its own line address exists on the ring. No data can be transmitted or received on the line until this logical ring fault is resolved.
Unknown	The FDDI MAC entity is performing the duplicate address test to determine if any other stations on the ring have the same address as the line.

Frame Strip Mode

The frame strip mode used by the station. This field can have one of the following values:

Source Address Match	The station strips frames from the ring that contain its own address in the source address field.
Bridge Strip	The station maintains a count of frames sent since obtaining the token, sends a void frame when the transmission is complete (two void frames if it is serving as ring purger), and strips the returning frames from the ring until the count of frames sent is decremented to zero. Bridge stripping is used by bridges because they are sensitive to no-owner frames and frequently send frames that do not contain their own address in the source address field.
Unknown	The station is not operating on the ring.

Last Station ID

If implemented, this is the 48-bit address of the station that last performed a successful Parameter Management Frame (PMF) change,

add, or remove operation. If not implemented, the phrase “Not implemented” is displayed.

Link State

The operational state of the FDDI MAC entity of the station. This field can have one of the following values:

Broken	A hardware problem exists.
Off Fault Recovery	The FDDI MAC entity is recovering from a logical ring fault such as a failure of the duplicate address test, a local or remote stuck beaconing condition, or ring operational oscillation.
Off Maintenance	The FDDI MAC entity is performing loopback testing and online diagnostics.
Off Ready	The FDDI MAC entity is ready for operation but is not yet connected to the logical ring.
On Ring Initializing	The FDDI MAC entity is connecting to the logical ring.
On Ring Running	The FDDI MAC entity is connected to the logical ring and is fully operational.
Unknown	The FDDI MAC entity is not connected to the ring.

Link UID

The 48-bit address of the physical port for the data link.

Loopback Mode

The operational state of loopback mode for the link entity. This field can have one of the following values:

False	Loopback mode is off. The link entity is not set up to receive frames that it transmits in order to perform loopback testing on the ring or of the physical port.
True	Loopback mode is on. The link entity is set up to receive frames that it transmits in order to perform loopback testing on the ring or of the physical port.

Negotiated TRT

The negotiated target token rotation time (TTRT) value is referred to as T_Neg in the ANSI FDDI specifications. It is negotiated during the claim token process.

Neighbor Physical Port Type

The type of the neighbor physical port. This field can have one of the following values:

- A The physical port on a dual attachment wiring concentrator (DAC) or dual attachment station (DAS) that connects to the incoming primary ring and the outgoing secondary ring of the FDDI dual ring.
- B The physical port on a dual attachment wiring concentrator (DAC) or dual attachment station (DAS) that connects to the outgoing primary ring and the incoming secondary ring of the FDDI dual ring.
- Master One of the physical ports on a wiring concentrator that connects to a single attachment station (SAS) such as a DECbridge 500 device.
- Slave The physical port on a single attachment station (SAS) that connects to a wiring concentrator or another SAS.
- Unknown Physical port type is undefined.

Old Downstream Neighbor Address

The 48-bit hardware address of the station that was previously on the downstream side of the ring from this station.

Old Upstream Neighbor Address

The 48-bit hardware address of the station that was previously on the upstream side of the ring from this station.

Physical Link Error Estimate

The current link error rate as estimated by the link error monitor (LEM). For a value of n , the actual rate is 1×10^{-n} .

Physical Port State

The operational state of the physical port. This field can have one of the following values:

- Broken The physical port failed its diagnostic tests and is nonoperational.
- Failed Same as Waiting, except that the physical port failed at least once; by failing the link confidence test (LCT) during initialization, by exceeding the link error monitor (LEM) threshold during operation, or because it is part of an illegal topology.

In use	The physical port established a connection and is fully operational.
Off maintenance	The physical port is reserved for diagnostic testing and loopbacks.
Off ready	The physical port is disabled.
Starting	The physical port received a response from its neighbor physical port and is exchanging information and performing the link confidence test (LCT) before completing the connection.
Unknown	The condition of the physical port is not known.
Waiting	The physical port is establishing a connection and is waiting for a response from its neighbor physical port.
Watching	Same as Starting, except that the physical port failed at least once; by failing the link confidence test (LCT) during initialization, by exceeding the link error monitor (LEM) threshold during operation, or because it is part of an illegal topology.

Physical Port UID

The 48-bit address of the physical port.

Reject Reason

The reason that the last connection on the physical port was lost. This field is updated every time the physical port loops through the Failed and Watching states. This field can have one of the following values:

LCT Both	The link confidence test (LCT) failed on both this physical port and the neighbor physical port.
LCT Local	The link confidence test (LCT) failed on this physical port.
LCT Remote	The link confidence test (LCT) failed on the neighbor physical port.
LEM Failure	The bit error rate on the physical port exceeded the link error monitor (LEM) threshold. The LEM monitors the quality of the link during operation.
No Reason	The physical port is initializing. This value is cleared when the physical port enters the In Use state.
Remote Reject	The neighbor physical port broke the connection for an unknown reason.
Standby	The physical port is not ready, it is initializing.

TNE Expired	The noise timer expired because a single noise event lasted for more than 1.31072 milliseconds. The noise timer is operational only when the physical port is In Use.
Topology Rules	The neighbor physical port is an illegal match for this physical port; for example, an A and an A or a Master and a Master.
Trace in Progress	A PC Trace occurred while the physical port was initializing. When a PC trace occurs, any physical ports that have not established a connection are shut down to prevent the topology from changing.
Trace Received-Trace Off	The physical port was momentarily disabled because it received a PC trace when its own PC trace function was disabled. The Trace Disable switch is designed to protect the physical port from faulty implementations of the PC trace algorithm. The Trace Disable switch is not remotely manageable.

Ring Error Reason

The reason there is an error condition on the ring. This field can have one of the following values:

Bridge Strip Error	A station using bridge frame stripping received a token before decrementing its Sent count to zero. In bridge strip mode, the station maintains a count of frames sent since obtaining the token, and decrements the count each time one of its frames returns.
Directed Beacon Received	A station that is stuck beaoning sent a frame to the directed beacon multicast address, indicating the suspected cause of the ring break. (A station is stuck beaoning when its FDDI MAC entity has been beaoning longer than the time defined by the ANSI FDDI parameter T_Stuck.) This is the last recovery procedure before initiating the PC trace.
Duplicate Address Detected	A station detected a duplicate of its own address.
Duplicate Token Detected	A station received a token while it was holding the token.
No Reason	The ring is operating correctly.

PC Trace Initiated	A station that is stuck beaconing has forced its upstream neighbors to perform their self-tests. (A station is stuck beaconing when its FDDI MAC entity has been beaconing longer than the time defined by the ANSI FDDI parameter T_Stuck.) PC trace is the most drastic fault recovery procedure.
PC Trace Received	The station received a PC trace frame, instructing the station to initiate a self-test.
Ring Beaconing Initiated	A station initiated the ring beacon process because its TRT timer expired before the claim token process recovered the ring. The beacon process locates the ring break. The station downstream from the break will be stuck beaconing. (A station is stuck beaconing when its FDDI MAC entity has been beaconing longer than the time defined by the ANSI FDDI parameter T_Stuck.)
Ring Init Initiated	The FDDI MAC entity of this station initiated the claim token process because it detected a configuration change or a missing token.
Ring Init Received	Another station initiated the claim token process because it detected a configuration change or a missing token.
Ring OP Oscillation	The ring is suffering from ring OP (operational) oscillation. That is, it repeatedly comes up briefly and then goes back into initialization. This problem is frequently caused by a duplicate address condition.
Ring Purge Error	The station serving as the ring purger received a token when it was not expecting one. The station expects two void frames and then the token when it is serving as the ring purger.

Ring Latency

The amount of time (in milliseconds) for a signal element to proceed completely around the entire ring.

Ring Purge Address

The 48-bit data link address of the station currently elected as Ring Purger.

Ring Purger State

The state of the ring purger algorithm of the station's FDDI MAC entity. This field can have one of the following values:

Candidate	The ring is operational and the FDDI MAC entity is bidding to become the ring purger by sending Candidate Hello frames to the ring purger multicast address. The station with the highest station ID becomes the ring purger.
Non Purger	The ring is operational and the FDDI MAC entity is not the ring purger, either because another station won the candidate bidding or because this line has a duplicate address.
Purger	The ring is operational and the FDDI MAC entity is serving as ring purger, constantly purging the ring of fragments and no-owner frames. The station periodically sends Ring Purger Hello frames to the ring purger multicast address.
Purger Off	The ring purger algorithm is not active because the ring is not operational.

Station State

The state of the station. This field can have one of the following values:

Loopback	The station is enabled to operate in loopback mode; it will not connect to the ring.
Off	The station is disabled.
On	The station is enabled to operate in normal operating mode.

Station UID

The 48-bit ID of the FDDI port of the station. The first two bytes are zero (0). The remaining bytes are the link address value of the first MAC of the station.

Upstream Neighbor Address

The 48-bit hardware address of the station that is on the upstream side of the ring from this station.

Upstream Neighbor Dup Addr Flag

The upstream neighbor's duplicate address status. This field can have one of the following values:

Absent	The duplicate address test passed.
Present	The duplicate address test failed.

A.2.3 FDDI Characteristics

This section lists FDDI characteristics alphabetically.

LEM Threshold

The link error monitor (LEM) threshold set for the physical port. The LEM monitors the bit error rate (BER) on the physical port during normal operation. When the bit error rate rises above the LEM threshold, the station disables the physical port, preventing it from disrupting the ring.

The LEM threshold is expressed as the absolute value of the exponent of the bit error rate. The legal range for the threshold is 5 through 8, corresponding to the range of bit error rates, which is 1×10^{-5} (0.00001) bit errors per second through 1×10^{-8} (0.00000001) bit errors per second.

Link Address

The 48-bit hardware address of this FDDI network interface.

Physical Port Type

The type of the neighbor physical port. This field can have one of the following values:

- A The physical port on a dual attachment wiring concentrator (DAC) or dual attachment station (DAS) that connects to the incoming primary ring and the outgoing secondary ring of the FDDI dual ring.
- B The physical port on a dual attachment wiring concentrator (DAC) or dual attachment station (DAS) that connects to the outgoing primary ring and the incoming secondary ring of the FDDI dual ring.
- Master One of the physical ports on a wiring concentrator that connects to a single attachment station (SAS) such as a DECbridge 500 device.
- Slave The physical port on a single attachment station (SAS) that connects to a wiring concentrator or another SAS.
- Unknown No connection has been established.

PMD Type

The type of physical medium to which this physical port is attached. This field can have one of the following values:

ANSI Multimode	Inexpensive thick core fiber combined with light-emitting diode (LED) sources and p-type intrinsic n-type (PIN) detectors.
ANSI Singlemode Type 1	Expensive thin core fiber combined with laser diode sources and avalanche photodiode (APD) detectors.
ANSI Singlemode Type 2	Expensive thin core fiber combined with laser diode sources and avalanche photodiode (APD) detectors.
ANSI SONET	Synchronous Optical Network

Requested TRT

The ANSI MAC parameter T_req, which is the requested value for the Token Rotation Timer. The default value is 8.0 milliseconds.

Restricted Token Timeout

This value limits how long a single restricted mode dialog can last before being terminated.

Ring Purger Enable

If True, this link participates in the Ring Purger election. If elected, the link performs the Ring Purger function.

SMT Max Version ID

The highest value supported for SMT Version ID. A value of 1 corresponds to SMT Revision 6.2.

SMT Min Version ID

The lowest value supported for SMT Version ID. A value of 1 corresponds to SMT Revision 6.2.

SMT Version ID

The version number of the FDDI Station Management (SMT) protocol.

Station ID

The 48-bit ID of this FDDI network interface for station management (SMT). The first two bytes are zero (0). The remaining bytes are the link address value of the first MAC of the station.

Station Type

The type of station. This field can have one of the following values:

DAS	A dual attachment station (DAS). A station that has one or two links and two physical ports, one of type A and one of type B.
SAS	A single attachment station (SAS).

Valid Transmission Time

The valid transmission time (TVX) used by the FDDI MAC entity. If the FDDI MAC entity does not receive a valid frame or unrestricted token within the valid transmission time, it initializes the ring. The default value is 2.621 milliseconds.

A.3 Monitoring the Token Ring Interface

You can use the `netstat -I tra0 -s` command to obtain a listing of the token ring counters and other attributes. The following is sample system output from this command:

```
tra0 Token ring counters at Thu Mar 24 07:33:00 1993
 82502 seconds since last zeroed
 2230 bytes received
 1704 bytes sent
   34 data blocks received
   20 data blocks sent
 288 multicast bytes received
   8 multicast blocks received
 306 multicast bytes sent
  13 multicast blocks sent
   0 unrecognized frames
   0 unrecognized multicast frames
   0 transmit failures
   0 transmit underrun errors
   1 line errors
   9 internal errors
   4 burst errors
   0 ARI/FCI errors
   0 abort delimiters transmitted
   3 lost frame errors
   0 receive data overruns
   0 frame copied errors
   0 token errors
   9 hard errors
   3 soft errors
   1 adapter resets
   1 signal loss
   5 beacon transmits
   2 ring recoveries
   0 lobe wire faults
   0 removes received
```

```

    0 single stations
    0 self test failures
tra0 Token ring and host information:
MAC address:                00-00-C9-19-4A-F3
Group address:              00-C0-00-80-00-00
Functional address:         00-C0-00-00-00-00
Physical drop number:       0
Upstream neighbor address:  00-00-10-C9-F5-3B
Upstream physical drop number: 0
Transmit access priority:   0
Last major vector:          Standby monitor present
Ring status:                No problems detected
Monitor contender:          Yes
Soft error timer value:     2000 ms
Local ring number:          0
Reason for transmitting beacon: No beacon
Reason for receiving beacon:  No beacon
Last beacon upstream neighbor address: 00-00-10-C9-F3-4A
Beacon station physical drop number: 0
Ring speed:                 4Mbps
Early token release:        False
Open status:                 Open
Token ring chip:            TMS380C26

```

A.3.1 Token Ring Counters

This section lists the token ring counters alphabetically.

abort delimiters transmitted

The number of times an abort delimiter was transmitted while transmitting data.

adapter resets

The number of times the adapter was reset.

ARI/FCI errors

The number of times a standby monitor present (SMP) MAC frame or active monitor present (AMP) MAC frame was received with the address recognized indicator (ARI) or frame copied indicator (FCI) bits set to zero, followed by another SMP MAC frame with the ARI and FCI bits set to zero.

beacon transmits

The number of beacon MAC frames transmitted.

burst errors

The number of times a burst error was detected.

bytes received

The number of bytes successfully received.

bytes sent

The number of bytes successfully transmitted.

data blocks received

The number of frames successfully received.

data blocks sent

The number of frames successfully transmitted.

frame copied errors

The number of times a frame with a station's recognized address had the frame copied indicator (FCI) set.

hard errors

The number of times a streaming error, frequency error, signal loss error, or internal error was detected.

internal errors

The number of times a recoverable internal error was detected.

line errors

The number of times a frame was repeated or copied, the error detected indicator (EDI) was zero in the incoming frame, or one of the following occurred:

- A code violation occurred between the starting delimiter and ending delimiter of the frame
- A code violation existed in the token
- A frame check sequence (FCS) error occurred

lobe wire faults

The number of times a wire fault condition was detected.

lost frame errors

The number of times an adapter was transmitting data and failed to receive the end of the frame it transmitted.

multicast blocks received

The number of frames successfully received in multicast frames.

multicast blocks sent

The number of frames successfully transmitted in multicast frames.

multicast bytes received

The number of bytes successfully received in multicast frames.

multicast bytes sent

The number of bytes successfully transmitted in multicast frames.

receive data overruns

The number of times a frame was received and the station had no available buffer space.

removes received

The number of times a remove ring station MAC frame was received.

ring recoveries

The number of times a ring recovery has occurred.

seconds since last zeroed

The number of seconds since the associated counter attributes were set to zero.

self test failures

The number of times the self test has failed.

signal loss

The number of times a broken ring, faulty wiring concentrator, transmitter malfunction, or receiver malfunction was detected.

single stations

The number of times there was only one station on the ring.

soft errors

The number of times an error MAC frame was transmitted.

token errors

The number of times an active monitor recognized an error condition that required a token be transmitted.

transmit failures

The number of times a transmit error (other than transmit underrun) occurred.

transmit underrun errors

The number of times a transmit underrun error occurred. This indicates the transmit first-in/first-out (FIFO) buffer became empty during frame transmission.

unrecognized frames

The number of times a received, individually addressed logical link control (LLC) frame was discarded because there was no data link port.

unrecognized multicast frames

The number of times a received LLC frame addressed to a multicast address was discarded because there was no data link port.

A.3.2 Token Ring and Host Information

This section lists the token ring and host information alphabetically.

Beacon station physical drop number

The physical location of the upstream station that transmitted a beacon.

Early token release

This field can have one of the following values:

- | | |
|-------|---|
| True | The station will release the token when it completes frame transmission. The default for 16 Mb/s rings. |
| False | The station will release the token when it receives the transmitted frame header. The default for 4 Mb/s rings. |

Functional address

The functional address of the station. Functional addresses identify predefined devices through bit-significant locally-administered group addresses. Some devices include:

Active monitor	C0 00 00 00 00 01
Ring Parameter Server (RPS)	C0 00 00 00 00 02
Ring Error Monitor (REM)	C0 00 00 00 00 08
Configuration Report Server (CRS)	C0 00 00 00 00 10
Source Route Bridge (SRB)	C0 00 00 00 01 00

Group address

The group address of the station.

Last beacon upstream neighbor address

The address of the upstream station that transmitted a beacon.

Last major vector

The function the adapter is to perform. This field can have one of the following values:

Active monitor present	The active monitor requested a standby monitor present MAC frame from its nearest downstream neighbor.
Beacon	Used by the adapter in the beacon process.
Change parameters	The network manager is changing adapter parameters.
Claim token	Used by the adapter in the monitor contention process.
Duplicate address test	The adapter is verifying that its address is unique on the ring.
Initialize ring station	The ring parameter server is setting adapter parameters.
Lobe media test	The adapter is testing the continuity of the wire in a loopback path.
Remove ring station	The network manager is requesting the adapter to remove itself from the ring.
Report error	The adapter is reporting soft error events to the ring error monitor.

Report monitor error	The adapter is reporting a problem with the active monitor or a possible duplicate station address to the ring error monitor.
Report new monitor	The active monitor adapter, after winning contention, is reporting this status to the network manager.
Report ring poll failure	The active monitor is reporting a failure in the ring poll process to the ring error monitor.
Report station address	The adapter is reporting its station address to the network manager.
Report station attachment	The adapter is reporting its attachment status to the network manager.
Report station state	The adapter is reporting its state to the network manager.
Report SUA change	The adapter is reporting a change in the stored upstream address (SUA) to the network manager.
Report transmit forward	The adapter is reporting a frame that has been forwarded and stripped to the network manager.
Request initialization	The adapter is requesting operational parameters from the ring parameter server.
Request station address	The network manager is requesting a report station address MAC frame from the adapter.
Request station attachment	The network manager is requesting a report station attachment MAC frame from the adapter.
Request station state	The network manager is requesting a report station state MAC frame from the adapter.
Response	The adapter is sending a positive acknowledgement to frames that require acknowledgement or is reporting syntax errors in the MAC frame.
Ring purge	Used by the active monitor during the ring purge process.
Standby monitor present	The adapter is responding to an active monitor present or standby monitor present MAC frame.
Transmit forward	Used in the transmit forward process.

Local ring number

The local ring number of the station.

MAC address

The MAC address of the station.

Monitor contender

Indicates whether the station will participate in the monitor contention process. This field can have the following values:

- No The station will not participate in the monitor contention process.
- Yes The station will participate in the monitor contention process.

Open status

The status of the adapter on the ring. This field can have one of the following values:

- Close The adapter is not operational on the ring.
- Open The adapter is operational on the ring.

Physical drop number

The physical location of the station.

Reason for receiving beacon

The reason why the adapter is receiving a beacon MAC frame. This field can have one of the following values:

- Bit streaming A monitor contention timeout occurred while an adapter was in monitor contention transmit mode and before a claim token MAC frame was received.
- Contention streaming A monitor contention timeout occurred while an adapter was in monitor contention mode (transmit or receive) and received one or more claim token MAC frames.
- No beacon The adapter is not receiving a beacon MAC frame.
- Signal loss An adapter detected a signal loss.

Reason for transmitting beacon

The reason why the adapter is transmitting a beacon MAC frame. This field can have one of the following values:

- Bit streaming A monitor contention timeout occurred while the adapter was in monitor contention transmit mode and before a claim token MAC frame was received.

Contention streaming	A monitor contention timeout occurred while the adapter was in monitor contention mode (transmit or receive) and received one or more claim token MAC frames.
No beacon	The adapter is not transmitting a beacon MAC frame.
Signal loss	The adapter detected a signal loss on the ring.

Ring speed

The ring speed: 4 Mb/s or 16 Mb/s.

Ring status

Status reported by the adapter to the driver. This field can have one of the following values:

Auto removal error	The adapter failed the lobe wrap test and removed itself from the ring.
Counter overflow	One of the adapter's error counters has exceeded its maximum value.
Hard error	The adapter is transmitting beacon frames to or receiving beacon frames from the ring.
Lobe wire fault	The adapter detected an open or short circuit in the cable between the adapter and the wiring concentrator.
No problems detected	The ring is operating normally.
Remove received	The adapter received a remove ring station MAC frame request and removed itself from the ring.
Ring recovery	The adapter is observing claim token MAC frames on the ring.
Signal loss	The adapter detected a loss of signal on the ring.
Single station	The adapter sensed that it is the only station on the ring.
Soft error	The adapter transmitted a report error MAC frame.
Transmit beacon	The adapter is transmitting beacon frames on the ring.

Soft error timer value

The number of milliseconds that elapse from the time the adapter detects a soft error until it sends a report error MAC frame to the ring error monitor.

Token ring chip

The type of chip used by the sending station.

Transmit access priority

The priority level at which this station can access the ring. This field can have a value from 0 (lowest priority) to 7 (highest priority).

Upstream neighbor address

The address of the upstream station.

Upstream physical drop number

The location of the upstream station.

B

Writing Automount and AutoFS Maps

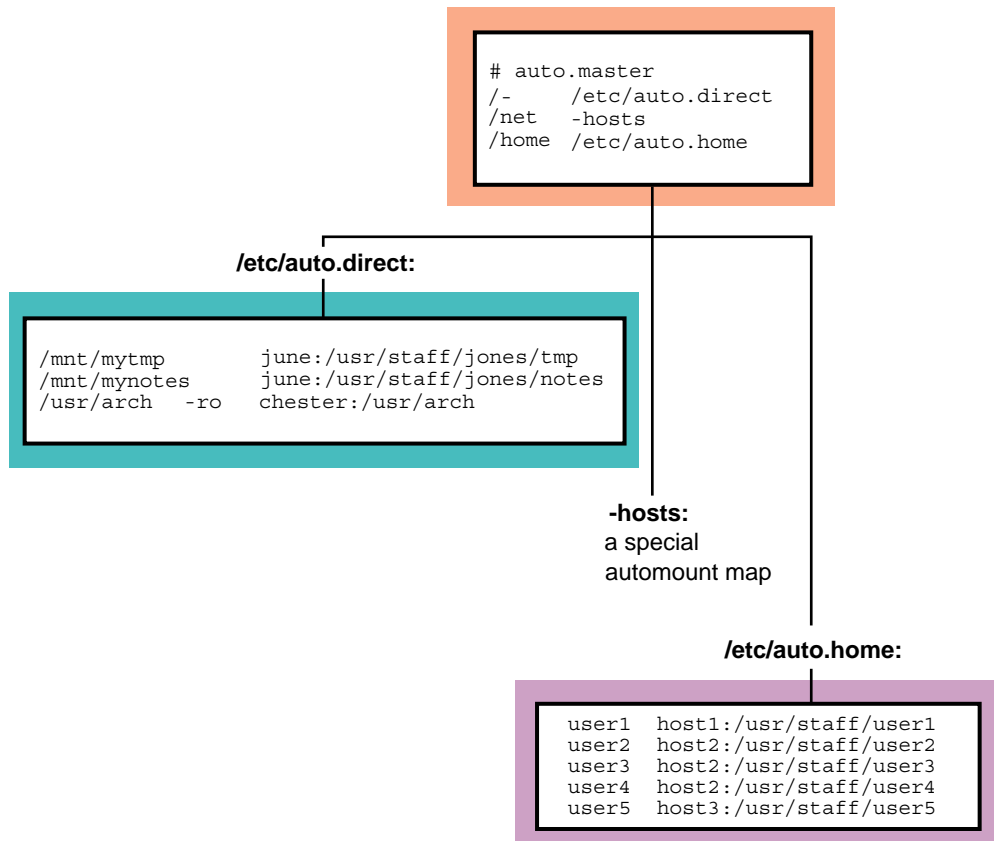

There are three types of Automount or AutoFS maps:

- Master
- Direct
- Indirect

The maps can be written in a variety of ways. They can be simple or can use multiple mounts, shared mounts, replicated file systems, or any combination of the three. As discussed in Section B.1, indirect maps can be written to reduce redundancy by using substitution characters and pattern matching. The examples in this section illustrate how the same maps can be rewritten in a number of ways.

Figure B-1 illustrates an `auto.master` map that points to the `/etc/auto.direct` direct map, the built-in `-hosts` map, and the `/etc/auto.home` indirect map. Each map to which the `auto.master` map points is expanded to show its sample contents. Note that all of the information contained in the master map can be specified on the command line. The master map, however, simplifies Automount and AutoFS administration.

Figure B-1: Sample automount Maps

ZK-0464U-AI

The following examples show how the `/etc/auto.direct` map in Figure B-1 can be rewritten using multiple mounts (Example B-1); multiple mounts and shared mounts (Example B-2); and multiple mounts, shared mounts, and replicated file systems (Example B-3).

Example B-1: Multiple Mounts in a Direct Map

<code>/mnt/mytmp</code>			<code>june:/usr/staff/jones/tmp</code>
<code>/mnt/mynotes</code>			<code>june:/usr/staff/jones/notes</code>
<code>/usr/arch</code>	<code>/</code>	<code>-ro</code>	<code>chester:/usr/arch \</code>
	<code>/bsd</code>	<code>-ro</code>	<code>chester:/usr/arch/bsd \</code>
	<code>/standards</code>	<code>-ro</code>	<code>chester:/usr/arch/standards \</code>
	<code>/dec/uws</code>	<code>-ro</code>	<code>chester:/usr/arch/dec/uws \</code>
	<code>/dec/ultrix</code>	<code>-ro</code>	<code>chester:/usr/arch/dec/ultrix</code>

Example B-2: Multiple Mounts and Shared Mounts in a Direct Map

```
/mnt/mytmp                june:/usr/staff/jones:tmp
/mnt/mynotes              june:/usr/staff/jones:notes
/usr/arch                 /                -ro  chester:/usr/arch \
                          /bsd                -ro  chester:/usr/arch/bsd \
                          /standards          -ro  chester:/usr/arch/standards \
                          /dec/uws              -ro  chester:/usr/arch/dec/uws \
                          /dec/ultrix          -ro  chester:/usr/arch/dec/ultrix
```

Example B-3: Multiple Mounts, Shared Mounts, and Replicated File Systems in a Direct Map

```
/mnt/mytmp                june:/usr/staff/jones:tmp
/mnt/mynotes              june:/usr/staff/jones:notes
/usr/arch                 /                -ro  chester:/usr/arch \
                          /bsd                -ro  chester:/usr/arch/bsd \
                          bazel:/src/bsd \
                          /standards          -ro  chester:/usr/arch/standards \
                          /dec/uws              -ro  chester:/usr/arch/dec/uws \
                          fiesta:/archive/uws\
                          /dec/ultrix          -ro  chester:/usr/arch/dec/ultrix
```

The `/etc/auto.direct` maps in the preceding examples could be rewritten as indirect maps. If the `/etc/auto.direct` map is rewritten to be an indirect map, the entry pointing to it in the `auto.master` map would look like the following:

```
/mnt    /etc/auto.indirect
```

Rewritten as a simple indirect map (`/etc/auto.indirect`), the `/etc/auto.direct` map in Figure B-1 would read as shown in Example B-4.

Example B-4: Simple Indirect Map

```
mytmp        june:/usr/staff/jones/tmp
mynotes      june:/usr/staff/jones/notes
arch        -ro  chester:/usr/arch
```

Note that the key is a simple pathname.

The following examples illustrate that indirect maps can also be rewritten using multiple mounts (Example B-5); multiple mounts and shared mounts

(Example B-6); and multiple mounts, shared mounts, and replicated file systems (Example B-7).

Example B-5: Multiple Mounts in an Indirect Map

mytmp			june:/usr/staff/jones/tmp
mynotes			june:/usr/staff/jones/notes
arch	/	-ro	chester:/usr/arch \
	/bsd	-ro	chester:/usr/arch/bsd \
	/standards	-ro	chester:/usr/arch/standards \
	/dec/uws	-ro	chester:/usr/arch/dec/uws \
	/dec/ultrix	-ro	chester:/usr/arch/dec/ultrix

Example B-6: Multiple Mounts and Shared Mounts in an Indirect Map

mytmp			june:/usr/staff/jones:tmp
mynotes			june:/usr/staff/jones:notes
arch	/	-ro	chester:/usr/arch \
	/bsd	-ro	chester:/usr/arch/bsd \
	/standards	-ro	chester:/usr/arch/standards \
	/dec/uws	-ro	chester:/usr/arch/dec/uws \
	/dec/ultrix	-ro	chester:/usr/arch/dec/ultrix

Example B-7: Multiple Mounts, Shared Mounts, and Replicated File Systems in an Indirect Map

mytmp			june:/usr/staff/jones:tmp
mynotes			june:/usr/staff/jones:notes
arch	/	-ro	chester:/usr/arch \
	/bsd	-ro	chester:/usr/arch/bsd \
			bazel:/src/bsd \
	/standards	-ro	chester:/usr/arch/standards \
	/dec/uws	-ro	chester:/usr/arch/dec/uws \
			fiesta:/archive/uws\
	/dec/ultrix	-ro	chester:/usr/arch/dec/ultrix

The `-hosts` map is a built-in map supplied by Automount and AutoFS. This map allows a client to access directories that are exported from any host in its `hosts` database. The location of the `hosts` database that your system uses is determined by the services running on your system (DNS, NIS, local) and how those services are specified in the `/etc/svc.conf` file. References to a particular host name result in all of the file systems that are exported from that host being mounted on the local system. For example, the following command results in all of the file systems that are exported from `host1` being mounted on the local system:

```
# cd /net/host1
```

The `/etc/auto.home` map shown in Figure B-1 is an indirect map that allows users to remotely mount their home directories. It can be rewritten using the ampersand (&) and asterisk (*) substitution characters.

The following example shows how the `/etc/auto.home` map in Figure B-1 can be rewritten using ampersands (&):

```
user1 host1:/usr/staff/&
user2 host2:/usr/staff/&
user3 host2:/usr/staff/&
user4 host2:/usr/staff/&
user5 host3:/usr/staff/&
```

B.1 Substitution and Pattern Matching

Both the `automount` and `autofs` commands recognize the following substitution characters, allowing you to eliminate redundancy within maps:

- The ampersand (&) can be used in both direct and indirect maps; however, it is most efficient and easily understood when used in indirect maps.
- The asterisk (*) can be used in indirect maps only.

Because the ampersand and asterisk are most easily used in indirect maps, this section discusses them in the context of indirect maps only. Recall that lines in indirect maps have the following syntax:

```
key          mount-options      location
```

Whenever the `automount` or `autofs` commands encounter an ampersand (&) in a line of an indirect map, they substitute the key in that line for the ampersand (&).

The following example is an indirect map that does not use ampersands:

```
#key          mount-options      location
#
host1         -rw,nosuid         host1:/home/host1
host2         -rw,nosuid         host2:/home/host2
```

Using the ampersand (&) as a substitution character, the entries read as follows:

```
#key          mount-options      location
#
host1         -rw,nosuid         &:/home/&
host2         -rw,nosuid         &:/home/&
```

You can use the asterisk (*) to substitute for lines that are all formatted similarly. Both daemons use the asterisk to match any host not listed as a

key in an entry before the asterisk. The following example shows how the asterisk (*) is typically used:

```
#key          mount-options      location
#
host1         -rw,nosuid          &:/home/&
host2         -rw,nosuid          &:/home/&
*             -rw,nosuid          &:/home/&
```

Suppose a user enters the following command:

```
% ls /home/host5
```

Either daemon recognizes the host name, `host5`, as the `key` and substitutes `host5` for each of the ampersands in the `location` field. The map is interpreted as follows for `host5`:

```
#key          mount-options      location
#
host5         -rw,nosuid          host5:/home/host5
```

Note

The `automount` and `autofs` commands ignore any entry that follows an asterisk.

B.2 Environment Variables

You can use the value of an environment variable in a map by adding a dollar sign (\$) prefix to its name. You also can use braces ({ }) to delimit the name of the variable from appended letters or digits.

Environment variables can be inherited from the environment or can be defined explicitly with the `-D` option on the command line. For example, you can invoke the `automount` daemon with the `HOST` variable by entering the following command:

```
# automount -D HOST=hostname
```

To define the same variable for the `autofs` daemon, enter the following command:

```
# autofs -D HOST=hostname
```

The following is an example of a direct map entry that uses the environment variable `HOST` to define subnetworks:

```
/mydir      -rw      server:/export/$HOST
```

B.3 Mounting File Systems

Automount and AutoFS provide several ways to mount remote directories and file systems:

- Multiple mounts
- Shared mounts
- Replicated file systems

B.3.1 Multiple Mounts

When you write direct and indirect maps, you can specify that different directories within a file system hierarchy be mounted from different servers. For example, if you mount the `/usr/local` file system on your machine, you can mount the various subdirectories within `/usr/local` from different servers.

The following example shows an entry in a direct map in which the directories `/usr/local/bin`, `/usr/local/src`, and `/usr/local/tools` are mounted from the machines `host1`, `host2`, and `host3`, respectively:

```
/usr/local\  
    /bin    -ro      host1:/usr/local/bin \  
    /src    -ro      host2:/usr/local/src \  
    /tools  -ro      host3:/usr/local/tools
```

This is a direct map because the key, `/usr/local`, is an absolute pathname. If this were an entry in an indirect map, the key would be a simple pathname, such as `local`. The key, `/usr/local`, comprises three subdirectories, each of which is a mount point for a remote directory on a different remote server. The example shows the entry split into four lines with the continuation lines indented for readability.

The preceding example shows multiple, nonhierarchical mounts under `/usr/local`. The following example shows a true hierarchical entry:

```
/usr/local \  
    /          -ro      host0:/usr/local \  
    /bin       -ro      host1:/usr/local/bin \  
    /src       -ro      host2:/usr/local/src \  
    /tools     -ro      host3:/usr/local/tools
```

The mount points used here for the hierarchy are `/`, `/bin`, `/src`, and `/tools`. Note that these mount points are relative to `/usr/local`. The mount point `/` mounts `/usr/local` from `host0`.

When file systems are mounted hierarchically, the entire hierarchy is treated as one object. Each file system is mounted on a subdirectory within another file system, and when a subdirectory within the hierarchy is referenced,

the daemon mounts the entire hierarchy. The entire hierarchy is also unmounted as one object. The only exception is specific to AutoFS.

Like the automount daemon, the `autofs` daemon creates symbolic links for file systems that are served locally. But if the `autofs` daemon encounters an entry in a list of hierarchical file systems that is served locally and would result in a circular symbolic link on the local system (for example, a link from the `/usr/local/bin` directory back to itself), the group semantic is lost. AutoFS will mount and unmount the file systems on an individual basis.

This happens because AutoFS is designed to mount a remote file system on (or create a symbolic link to) the designated mount point itself. It does not, as Automount does, create an additional symbolic link back to a special `/tmp_mnt` directory from which the remote file system is actually served.

B.3.2 Shared Mounts

When multiple directories within the same remote directory are mounted, the `location` field can be specified as follows:

```
host:path:subdir
```

Note

AutoFS does not support this syntax. If the `autofs` command encounters this syntax, it converts the final colon (`:`) to a slash (`/`) and treats the entry as a typical AutoFS mount.

The `host` field is the remote host from which to mount the file system. The `path` field is the pathname of the directory to mount, and the `subdir` field, if specified, is the name of the subdirectory to which the symbolic link is made. This prevents duplicate mounts of the same remote file system when multiple subdirectories within it are accessed.

Suppose an indirect map called `/auto.myindirect` is specified in a master file as follows:

```
/mydir          /auto.myindirect
```

And the `/auto.myindirect` map consists of the following entries:

```
mybin          host1:/usr/staff/diane:bin
mystuff       host1:/usr/staff/diane:stuff
```

When a user accesses a file in `/mydir/mybin`, the automount daemon mounts `host1:/usr/staff/diane`, but creates a symbolic link called `/mydir/mybin` to the `bin` subdirectory in the temporarily mounted file system. If a user immediately tries to access a file in `/mydir/mystuff`, the automount daemon needs only to create a symbolic link that points to the

stuff subdirectory because the `/usr/staff/diane` directory is already mounted. With the following map, the daemon would perform two separate mount operations:

```
mybin          host1:/usr/staff/diane/bin
mystuff        host1:/usr/staff/diane/stuff
```

B.3.3 Replicated File Systems

You can specify multiple locations for a single mount. If a file system is located on several servers and one of the servers is disabled, the file system can be mounted from one of the other servers. This makes sense only when mounting a read-only file system.

In the following example, the reference pages can be mounted from `host1`, `machine2`, or `system3`:

```
/usr/man\
    -ro,soft      host1:/usr/man \
                  machine2:/usr/man \
                  system3:/usr/man
```

The preceding example can also be expressed as a list of servers, separated by commas and followed by a colon and the pathname, for example:

```
/usr/man -ro,soft host1,machine2,system3:/usr/man
```

This syntax is valid only if the pathname is the same on each server.

When you access the reference pages, the `automount` daemon issues a ping (NFS v2 loop request) to each of the specified servers concurrently. The server that first responds to the ping request is used for the mount. In contrast, the `autofs` daemon first checks to see if the file system can be served locally. If so, the daemon uses a symbolic link to access the resource. If not, it selects the first server on the list that responds to a mount request.

C

NIS ypservers Update Scripts

This appendix provides the following scripts for updating the `ypservers` map:

- `addypserver` — Adds a slave server
- `rmypserver` — Removes a slave server

C.1 Add Slave Server Script

Use the following procedure to create the `addypserver` script on an NIS master server:

1. Create an `addypserver` file in the `/var/yp` directory and insert the following lines. Where `method` appears, specify the format in which the map is to be stored:

```
#!/bin/sh
PATH="/usr/bin:/var/yp:$PATH"
if [ $# != 1 ]; then
    echo "usage: $0 server"; exit 1
fi
DOMAIN=`/usr/sbin/rcmgr get NIS_DOMAIN`
cd /var/yp
echo "
Adding $1 to ypservers map for domain DOMAIN ..."
(/var/yp/makedbm -u $DOMAIN/ypservers;\
echo $1 $1) | /var/yp/makedbm -a method tmpmap
mv tmpmap.dir $DOMAIN/ypservers.dir
mv tmpmap.pag $DOMAIN/ypservers.pag
yppush ypservers
```

2. Set the permissions to 700, using the `chmod` command as follows:

```
# chmod 700 /var/yp/addypserver
```

To add `host1` to the `ypservers` map, enter the following command:

```
# /var/yp/addypserver host1
```

You still need to edit the NIS master server's master `hosts` file and add an entry for the slave server, if it is not already in the `hosts` file. Then, update and distribute the map by entering the `make` command. See Section 9.4.1 for more information.

C.2 Remove Slave Server Script

Use the following procedure to create the `rmypserver` script on an NIS master server:

1. Create a `rmypserver` file in the `/var/yp` directory and insert the following lines. Where *method* appears, specify the format in which the map is to be stored:

```
#!/bin/sh
PATH="/usr/bin:/var/yp:$PATH"
if [ $# != 1 ]; then
    echo "usage: $0 server"; exit 1
fi
DOMAIN=`/usr/sbin/rcmgr get NIS_DOMAIN`
cd /var/yp
echo "
Removing $1 from ypservers map for domain DOMAIN ..."
/var/yp/makedbm -u $DOMAIN/ypservers | grep -v $1 \
| /var/yp/makedbm -a method tmpmap
mv tmpmap.dir $DOMAIN/ypservers.dir
mv tmpmap.pag $DOMAIN/ypservers.pag
yppush ypservers
```

2. Set the permissions to 700, using the `chmod` command as follows:

```
# chmod 700 /var/yp/rmypserver
```

To remove `host1` from the `ypservers` map, enter the following command:

```
# /var/yp/rmypserver host1
```

D

NFS Error Messages

You might see the following types of NFS error messages:

- Server error messages
- Client error messages

D.1 Server Error Messages

The following error messages are issued to the screen or console or sent to the `syslogd` daemon.

```
authget: unknown authflavor n  
authflavor
```

Explanation: Each NFS request has an authentication type. This message is displayed if the type is not AUTH_UNIX.

User Action: Have the client application use the AUTH_UNIX authentication type.

```
fh3tovp: bad length: n
```

Explanation: A client sent a bad file handle to the server.

```
NFS request from unprivileged port, source IP address = n
```

Explanation: The server, performing NFS server port monitoring, received an NFS request from a nonprivileged port (greater than or equal to 1024) on a client. This might indicate a security problem.

```
NFS server: fs(n,n) not mounted; client address = n.n.n.n
```

Explanation: The client requested a file on a file system that is not mounted or does not exist on the server. This can occur if a file system is unmounted while clients are using it or if the client passed an invalid file handle.

User Action: Make sure that the appropriate file system is mounted on the NFS server. If the file system is mounted on the same device, have the client system retry the operation. If the file system is mounted on a different device, have the client system unmount and remount the remote file system.

```
NFS server: stale file handle fs(n,n) file file gen n,  
client address = n.n.n.n errno n
```

Explanation: The client accessed a file that no longer exists. The file was deleted either by the server or by another client.

```
NFS server: unexported fs(n,n) file file, client address  
= n.n.n.n
```

Explanation: A client that previously had access to a file system can no longer access the file system, either because of changes in the `/etc/exports` file or in the net group mapping.

User Action: Have the client system unmount the file system.

```
rfs_dispatch botch
```

Explanation: The duplicate request cache routine returned an illegal value.

```
rfs_dispatch: bad rfs reply n  
ret
```

Explanation: A server routine did not return a value or returned an incorrect value.

```
rfs_dispatch: dispatch error, no reply  
rfs_dispatch: sendreply failed
```

Explanation: Possible reasons for this message include the following:

- The server is out of memory and cannot process or reply to a request.
- The server cannot find a route to the source.
- There is some other network-related problem.

```
too many nfsds
```

Explanation: There are more `nfsd` daemons registered with NFS than were started.

D.2 Client Error Messages

This appendix provides an explanation and suggested user actions for the following classes of client error messages:

- Remote mount error messages
- Automount error messages
- AutoFS error messages
- Console error messages

Within each section, error messages are listed alphabetically.

D.2.1 Remote Mount Error Messages

The following error messages are displayed if you are mounting directories or file systems from remote systems:

```
mount: unknown special file or file system xxx
```

Explanation: There is no entry in the `/etc/fstab` file for the mount point that you specified in the `mount` command line.

User Action: Verify that there is an entry in the `/etc/fstab` file for the file system. If not, add an entry. If one exists, look for syntax errors or typos in the entry. See `fstab(4)`.

```
/etc/fstab: No such file or directory
```

Explanation: The `/etc/fstab` file does not exist. The `mount` command discovered this when it tried to look up the name specified on the command line.

User Action: Create an `/etc/fstab` file and include the appropriate entries. See `fstab(4)`.

```
nfs_mount: Permission denied for yyy
```

Explanation: Your host name is not in the export list for the file system or directory you want to mount from the server.

User Action:

1. Get a list of your host's exported file systems and directories by using the `showmount -e` command. For example, enter the following command if your server's host name is `host2`:

```
# /usr/bin/showmount -e host2
```
2. If the file system or directory you want to mount remotely is not on the list, or if your host or network group name is not on the user list for the file system or directory, log in to the server and look in the `/etc/exports` file for the correct file system entry.
3. If the file system or directory name is in the `/etc/exports` file, but not in the output from `showmount`, the failure is in the `mountd` daemon. The `mountd` daemon could not parse that line in the file, could not find the file system or directory, or the file system or directory name was not a locally mounted file system.

If the file system or directory name is in the `/etc/exports` file and Network Information Service (NIS) is configured, verify

that the `yplibd` daemon is running; it might have stopped. See `exports(4)` for further information.

```
nfs_mount: cannot mount xxx on yyy: Mount device busy
```

Explanation: The file system or directory you are trying to mount is already mounted.

```
nfs_mount: cannot mount xxx on yyy: No such file or directory
```

Explanation: The local mount point does not exist.

User Action: Verify that the mount point exists and that it is spelled correctly.

```
nfs_mount: cannot mount xxx on file: Not a directory
```

Explanation: Either the remote file system or the local mount point is not a directory.

User Action: Verify that the remote file system and the local mount point are directories (not files) by using the `ls` command. Verify the spelling of both directories.

```
nfs_mount: cannot mount xxx on yyy: Not owner
```

Explanation: You must mount the remote file system or directory as superuser (root) on your system.

```
nfs_mount: illegal file system name xxx; use host:pathname
```

Explanation: You did not specify the name of the server when you issued the `mount` command.

User Action: For example, to mount the file system `/usr/src` from the server `host2`, enter the following command:

```
# mount host2:/usr/src /host2/usr/src
```

```
nfs_mount: invalid directory name xxx
directory pathname must begin with '/'.
```

Explanation: The mount point on the local (client) system must be an absolute path starting at the root directory (`/`).

```
nfs mount: RPC: Authentication error;
why=Client credential too weak
```

Explanation: The server is allowing client superuser mounts only and you are not a superuser. See `mountd(8)` for further information.

```
nfs_mount: RPC: Authentication error;
why=Server rejected credential
```

Explanation: Possible reasons for this error message include the following:

- The server is running with Internet address verification turned on and it cannot resolve your Internet address. If your system has multiple network interfaces configured, the server must be able to resolve all IP addresses, either using the local `/etc/hosts` file or the distributed `hosts` file.
- The server is running with domain or subdomain verification turned on and your system is not in the same domain or subdomain as the server.

See `mountd(8)` for further information.

```
nfs_mount: xxx server not responding: port mapper failure
rpc_timed out Giving up on yyy
```

Explanation: The server you are trying to mount from is down, or its port mapper is inoperative.

User Action:

1. Log in remotely to the server. If you are able to log in, the network is working.
2. Execute the `rpcinfo` command from the server. For example, for a server named `host2`, you would enter the following command:

```
# /usr/sbin/rpcinfo -p host2
```

If the port mapper is running properly on the server, the `rpcinfo` command lists the registered program numbers. If it does not, restart the port mapper on the server. You also need a port mapper running on the client host; if it is not running there, start it. See `portmap(8)` for more information.

3. After you restart the port mapper, stop the NFS daemons by entering the following command:

```
# /sbin/init.d/nfs stop
```

If NIS is running, stop the `ypbind` daemon on the server. Use the `ps` command to obtain the process ID (PID) and the `kill` command to stop the process:

```
# ps -A | grep ypbind
  439 ??      I          0:00.02 /usr/sbin/ypbind ...
170866 pts/3   S +        0:00.01 grep ypbind
# kill -9 439
```

4. If you stopped the `ypbind` daemon, restart it by entering the following command:

```
# /usr/sbin/ypbind &
```

Restart the NFS daemons on the server by entering the following command:

```
# /sbin/init.d/nfs start
```

```
nfs_mount: xxx server not responding: rpc prog not registered
```

Explanation: The `mount` command got through to the port mapper, but the NFS `mountd` daemon was not registered.

User Action:

1. Log in to the server.
2. Verify that the `/usr/sbin/mountd` file exists by using the `ls` command.
3. Run the `ps` command to see if the `mountd` daemon is running. If it is not running, restart it by entering the following command:

```
# /usr/sbin/mountd
```

```
Can't get net id for host
```

Explanation: There is no entry in the `/etc/hosts` file for the NFS server specified in the `mount` command line. If NIS is running, there is no entry in the `hosts` NIS map for the host name specified. If BIND is running, there is no entry in the `hosts` database for the host name specified.

D.2.2 Automount Error Messages

The following error messages are issued to the screen or console or sent to the `syslogd` daemon by the `automount` program:

```
bad entry in map mapname
```

Explanation: The map entry in *mapname* is malformed and the `automount` program cannot interpret it.

User Action: Verify the entry; you might need to include escape characters.

```
Can't mount mountpoint: reason
```

Explanation: The `automount` program cannot mount itself at *mountpoint*. The error is indicated in the *reason* statement.

couldn't create directory: *reason*

Explanation: The automount program could not create a directory. The error is indicated in the *reason* statement.

dir *mountpoint* must start with '/'

Explanation: The *mountpoint* must have a full pathname.

User Action: Verify both the spelling and path name of the mount point.

hierarchical mountpoint: *mountpoint*

Explanation: The automount program will not allow itself to be mounted within an automounted directory.

User Action: Use another strategy to mount the directory.

host *hostname* not responding

Explanation: The automount program attempted to mount from *hostname* but received no response or failed. These errors could indicate a server or network problem.

hostname:filesystem server not responding

Explanation: The automount program attempted to mount from *hostname* but received no response or failed. These errors could indicate a server or network problem.

hostname: exports: rpc_err

Explanation: The automount program encountered an error while attempting to get the list of exported file systems and directories that it is allowed to mount from *hostname*.

This error occurs when a user attempts to access a mount point that has the `-hosts` map associated with it. This error indicates a server or network problem.

hostname:filesystem already mounted on *mountpoint*

Explanation: The automount program is attempting to mount a file system on a mount point that has already been mounted with that file system.

map *mapname*, key *key*: bad

Explanation: The map entry in *mapname* is malformed and the automount program cannot interpret it.

User Action: Verify the entry; you might need to include escape characters.

mapname: Not found

Explanation: The automount program cannot locate the map it requires. This message is returned only when you specify the `-v` option.

mapname: *yp_err*

Explanation: The automount program encountered an error when looking up an NIS map entry.

Mount of *hostname:filesystem* on *mountpoint:* *reason*

Explanation: The automount program attempted to mount from *hostname* but received no response or failed. These errors could indicate a server or network problem.

mountpoint: Not a directory

Explanation: The *mountpoint* exists but is not a directory.

User Action: Verify both the spelling and pathname of the mount point.

mountpoint-pathname from *hostname:* absolute symbolic link

Explanation: The automount program detected that *mountpoint* is an absolute symbolic link (begins with `/`). The content of the link is *pathname*. Because this might have undesired consequences on the client, the automount program will not mount on absolute symbolic links.

no mount maps specified

Explanation: The automount program cannot find any maps to serve, nor can it find any NIS maps. This message is returned only when you specify the `-v` option.

WARNING: *hostname:file system* already mounted on *mountpoint*

Explanation: The automount program is mounting itself on top of an existing mount point. This message is a warning only.

WARNING: *mountpoint* not empty!

Explanation: The *mountpoint* directory is not empty. This message is returned only when you specify the `-v` option. It is warning you that the previous contents of *mountpoint* will not be accessible while the mount is in effect.

The following error messages can occur when a file system is exported from multiple servers as specified in a multiple-server map entry. They indicate possible network problems that can occur when the `automount` daemon requests a response from the servers.

Cannot create socket for broadcast rpc: `rpc_err`

Explanation: No server in a multiple-server map entry is responding. This indicates that the replicated file system could not be reached on any of the specified servers.

Cannot receive reply to many_cast: `rpc_err`

Explanation: No server in a multiple-server map entry is responding. This indicates that the replicated file system could not be reached on any of the specified servers.

Cannot send broadcast packet: `rpc_err`

Explanation: No server in a multiple-server map entry is responding. This indicates that the replicated file system could not be reached on any of the specified servers.

Many_cast select problem: `rpc_err`

Explanation: No server in a multiple-server map entry is responding. This indicates that the replicated file system could not be reached on any of the specified servers.

NFS server (pid `n@mountpoint`) not responding still trying

Explanation: An NFS request to the `automount` daemon with PID `n` serving mount point has timed out. The `automount` daemon might be overloaded or not running.

User Action: If the condition persists, reboot the client. You can also do the following:

1. Exit all processes that are using automounted directories.
2. Kill the current `automount` process.
3. Restart the `automount` process from the command line.

Remount `hostname:filesystem` on `mountpoint` server not responding

Explanation: The `automount` program was attempting to remount `filesystem` because it discovered that a part of the automounted hierarchy at the `mountpoint` was busy. The remote file system's server, `hostname`, did not respond to the mount request. This error indicates a server problem.

trymany: servers not responding: *reason*

Explanation: No server in a multiple-server map entry is responding. This indicates that the replicated file system could not be reached on any of the specified servers.

D.2.3 AutoFS Error Messages

The following sections describe error messages for the two components of AutoFS: the `autofs` daemon and the `autofsmount` command.

D.2.3.1 `autofs` Messages

The following error messages are issued to the screen or console or sent to the `syslogd` daemon by the `autofs` program:

`autofs not configured`

Explanation: AutoFS is not properly configured in the kernel.

User Action: If necessary, add the `AUTOFS` option to the kernel configuration file and rebuild the kernel. See the *System Administration* for more information on modifying and rebuilding the kernel.

`autofs: Entire cluster not up to same version`

Explanation: All of the nodes in the TruCluster Server cluster are not running the same version of the operating system.

User Action: Install the same version of the operating system, Version 5.1 or higher, on all nodes.

`Cannot create socket for nfs: reason`

Explanation: Network socket creation failed due to *reason*.

`can't mount hostname`

Explanation: A mount request was rejected by the `mountd` daemon on *hostname*. This error usually indicates a permissions problem or that the file system does not exist.

User Action: Verify the export permissions in the `/etc/exports` file on the server and verify that the file system exists.

`Can't ping mountd version NFS-version at server hostname
reason`

Explanation: The `autofs` daemon attempted to communicate with the `mountd` daemon on the *hostname* server, but received no response.

User Action: Verify the status of the network and verify that the server is properly configured and running NFS services.

`cfg_subsys_state` returned `errorcode`

Explanation: AutoFS is not properly configured in the kernel.

User Action: If necessary, add the `AUTOFS` option to the kernel configuration file and rebuild the kernel. See the *System Administration* for more information on modifying and rebuilding the kernel.

`host hostname` not responding

Explanation: The `autofs` daemon attempted to mount from `hostname` but it received no response or the request failed. These errors could indicate a server or network problem.

User Action: Verify the status of the network and verify that the server is properly configured and running NFS services.

`hostname exports: rpc_err`

Explanation: The `autofs` daemon encountered an error while attempting to get the list of exported file systems and directories that is allowed to mount from `hostname`. This occurs during attempted access to a mount point with the `-hosts` map. It indicates a server or network problem.

User Action: Verify the status of the network and verify that the server is properly configured and running NFS services.

`hostname: mountd` not responding `reason`

Explanation: The `autofs` daemon attempted to communicate with the `mountd` daemon on the `hostname` server, but received no response.

User Action: Verify the status of the network and verify that the server is properly configured and running NFS services.

`hostname: server's portmap` not responding

Explanation: The `autofs` daemon attempted to communicate with the `portmap` daemon on the `hostname` server, but received no response.

User Action: Verify the status of the network and verify that the server is properly configured and running NFS services.

lookup_addr: gethostbyname failed *error* for *hostname*

Explanation: The `autofs` daemon was unable to obtain a network address for the named host.

User Action: Verify the address for the host in the local hosts file and the DNS or NIS database. Verify that the DNS or NIS server is up and running.

match *mapname:keyname* failed: *reason*

Explanation: The `autofs` daemon is having a problem reading the map file *mapname* to find key *keyname*. The error is indicated in the *reason* statement.

Mount of *hostname:filesystem* on *mountpoint*: *reason*

Explanation: The `autofs` daemon attempted to mount from *hostname*, but it received no response or the request failed. These errors could indicate a server or network problem.

User Action: Verify the status of the network and verify that the server is properly configured and running NFS services.

Unable to locally serve *filesystem*

Explanation: Locally serving the file system would result in a circular symbolic link.

User Action: Choose a different mount point for the file system, or specify a different host to serve the file system.

D.2.3.2 autofs mount Messages

autofs is not configured or not enabled

Explanation: AutoFS is not properly configured in the kernel.

User Action: If necessary, add the `AUTOFS` option to the kernel configuration file and rebuild the kernel. See the *System Administration* for more information on modifying and rebuilding the kernel.

Cluster nodes not all at same version

Explanation: All of the nodes in the TruCluster Server cluster are not running the same version of the operating system.

User Action: Install the same version of the operating system, Version 5.1 or higher, on all nodes.

Intercept *filesystem* mount failed: *reason*

Explanation: The attempt to create an intercept mount point for *filesystem* has failed due to *reason*. The `autofs` command issues this error message for direct map entries, and when running in verbose mode, for indirect map entries as well.

Map *mapname* does not exist

Explanation: The `autofs` command could not find the specified direct or indirect map file.

User Action: Ensure that you have specified the proper location for the map files on the command line or in your master map file.

Note: Indirect entry in map *mapname* with key *keyname* cannot be locally served with the `mounton` and `mountfrom` directories as defined.

Explanation: An external server will be chosen to avoid a circular symbolic link.

Note: The hierarchical entry in map *mapname* for *keyname* cannot be served locally

Explanation: An external server will be chosen to avoid a circular symbolic link.

Note: The shared map entry in map *mapname* with key *keyname* will be converted to a non-shared entry

Explanation: AutoFS does not support the shared mount syntax of Automount. It converts all shared map entries to their non-shared counterparts.

Unmount *filesystem*: *reason*

Explanation: An attempt to unmount *filesystem* has failed with *reason*.

Warning: Cannot support the hierarchy in map *mapname* with key *keyname* with the `mounton` and `mountfrom` directories as defined.

Explanation: The hierarchical direct map entry for subdirectory / cannot be supported, as no external servers are listed and locally serving it would create a circular symbolic link. The file systems in the map entry will be treated as though they are individual map entries.

User Action: Specify an external server or change the key and/or the location of the file system in question to avoid a circular symbolic link.

Warning: Skipping entry in map *mapname* with key *keyname*

Explanation: The file system will be locally served. No intercept mount point will be created, only a symbolic link.

Warning: The hierarchical entry in map *mapname* for *keyname* will not work.

Explanation: A hierarchical direct map entry for some subdirectory other than / cannot be supported, as no external servers are listed and locally serving it would create a circular symbolic link. The file systems in the map entry will be treated as though they are individual map entries.

User Action: Specify an external server or change the key and/or the location of the file system in question to avoid a circular symbolic link.

Warning: There are no servers available for this entry

Explanation: In the context of previous messages for this map entry, this error message indicates that locally serving the file system would create a circular symbolic link, and no external servers are specified.

User Action: Specify an external server or change the key and/or the location of the file system in question to avoid a circular symbolic link.

D.2.4 Console Error Messages

The following error messages might be displayed on the NFS client system console and in the error logger. They note an NFS file access failure.

NFS server *hostname* not responding, still trying

Explanation: File operations in a hard-mounted file system are suspended because communication between the client and the server has stopped.

NFS server *hostname* ok

Explanation: File operations have resumed.

NFS *file operation* failed for server *hostname*: *reason*

Explanation: If the operation is in a soft-mounted file system and the server is inoperable, the reason for the failure is that the operation timed out.

NFS write error, server *hostname*, remote file system full

Explanation: A write operation failed because the remote file system is full.

NFS write error *errno*, server *hostname*, fs(*n*,*n*), file *file*

Explanation: A write operation was refused by the server. The *fs* and *file* variables are parts of the file handle (fhandle). See `errno(2)` for a description of write errors.

E

uucp Messages

This appendix provides a description and suggested user actions for the following uucp messages:

- Status and log file messages
- tip error messages

E.1 Status and Log File Messages

The messages in this section might appear in uucp status or log files. Use the `uulog` or `uustat` command to see the status messages.

ASSERT ERROR

An ASSERT error occurred, indicating a condition that only a system manager can solve. ASSERT errors are stored in the `/usr/spool/uucp/.Admin/errors` file and have the following form:

```
ASSERT ERROR (prog)pid: xxxx (date/time) error error-location
```

The variables have the following meaning:

<i>prog</i>	Name of the program generating the error.
<i>xxxx</i>	Process ID (PID) of the program.
<i>date/time</i>	Data and time when the error occurred.
<i>error</i>	A message describing the error. The message might include arguments. If there is a value contained in parentheses following the message, this value is often the error number (<code>errno</code>).
<i>error-location</i>	Name and version of the source file and the line in the file where the error occurred.

Table E-1 lists the ASSERT error messages.

Table E-1: ASSERT Error Messages

Error Message	Explanation and User Action
BAD LINE <i>line</i> (<i>num</i>)	<p>The <code>/usr/lib/uucp/Devices</code> file has a bad line: <i>line</i> is the bad line and <i>num</i> is the number of fields found in the line.</p> <p>Correct the entry in the file. See <code>Devices(4)</code> for information on the file entries.</p>
BAD LOGIN_UID (-1) BAD UID (-1) CAN NOT FIND UID (<i>num</i>)	<p>The user ID used by the process is not currently logged in and is not defined in the <code>/etc/passwd</code> file or the networks database, if using NIS.</p> <p>Check your user ID by using the <code>id</code> command, and change the entry in the <code>/etc/passwd</code> file or the networks database, if using NIS.</p>
BAD SPEED (<i>num</i>)	<p>An unsupported baud rate (<i>num</i>) was specified.</p> <p>Check the command arguments or <code>uucp</code> configuration files. Then run <code>uucpsetup</code> to change the baud rate.</p>
CAN'T CHDIR <i>dir</i> (<i>num</i>)	<p>A command to change to directory <i>dir</i> failed with <code>errno num</code>. The <code>uucp</code> program required read access to the directory.</p> <p>Check the permissions on the directory. If the directory does not exist, check the permissions on the spool directory.</p>
CAN'T CLOSE file (<i>num</i>) CAN'T CREATE file (<i>num</i>)	<p>Could not close file with <code>errno num</code>.</p> <p>Could not open file with <code>errno num</code>. The <code>uucp</code> program needs write access to the file or directory.</p> <p>Check the permissions on the file and directory.</p>
CAN'T LINK file (<i>num</i>)	<p>Could not link a source file to the work file <i>file</i> in the <code>uucp</code> spool directory with <code>errno num</code>.</p> <p>Check the spool directory permissions.</p>
CAN'T LOCK LCK.SQ. <i>sys</i> (0)	<p>Could not lock the <code>/var/spool/locks/LCK.SQ. sys</code> file for system <i>sys</i>.</p> <p>Check the time and permissions on the file. If it is old, delete the file.</p>

Table E-1: ASSERT Error Messages (cont.)

Error Message	Explanation and User Action
CAN'T OPEN file (<i>num</i>)	<p>Could not open file with errno <i>num</i>. The <code>uucp</code> program needs write access to the file or directory.</p> <p>Check the permissions on the file and directory.</p>
CAN'T STAT file (<i>num</i>)	<p>The <code>uucico</code> daemon could not obtain information about the file with errno <i>num</i>.</p> <p>Check the permissions on the file.</p>
CAN'T UNLINK file (<i>num</i>)	<p>Could not unlink the file with errno <i>num</i>.</p> <p>Check the permissions on the file.</p>
CAN'T WRITE file (<i>num</i>)	<p>Could not open the file with errno <i>num</i>. The <code>uucp</code> program needs write access to the file or directory.</p> <p>Check the permissions on the file and directory.</p>
FILE EXISTS file (<i>num</i>)	<p>The file already exists and an <code>access()</code> call on that file returned errno <i>num</i>. The file is a <code>uucp</code> work file that was not cleaned up by another <code>uucp</code> process.</p>
No uucp server (0)	<p>The <code>uucp</code> service is not defined in the <code>/etc/services</code> file.</p> <p>Edit the <code>/etc/services</code> file and add a <code>uucp</code> entry.</p>
SYSLST OVERFLOW (<i>num</i>)	<p>There are too many jobs queued for a single system. The number of jobs is <i>num</i>.</p> <p>Use the <code>uustat -q</code> command and examine the queue. If the jobs are not old, try the request again. If there are old jobs in the queue, use the <code>uucleanup</code> command to clean out the queue. See <code>uucleanup(8)</code> for more information.</p>
TOO MANY LOCKS (<i>num</i>)	<p>The system limit on the number of lock files was exceeded while creating lock file <i>num</i>.</p> <p>Retry the request after the the current activity is completed.</p>

Table E-1: ASSERT Error Messages (cont.)

Error Message	Explanation and User Action
<code>XMV ERROR file (num)</code>	<p>The <code>uuxqt</code> daemon could not move the execute file to the <code>.Xqtdir</code> directory in the <code>uucp</code> spool area and failed with <code>errno num</code>.</p> <p>Use the <code>ls -l</code> command and verify that the <code>.Xqtdir</code> directory is owned by <code>uucp</code> and has a <code>775</code> permission.</p>

BAD LOGIN/MACHINE COMBINATION

Explanation: There are two possible reasons for this message:

- The `VALIDATE` option for the local system is set in the Permissions file on the remote system and the local system's user name does not match the `LOGNAME` entry for the system in the remote system's Permissions file.
- The local system's user name has no corresponding `LOGNAME` entry in the remote system's Permissions file.

User Action: Either ask the remote system administrator to add a `LOGNAME` entry for that user name, or edit the `Systems` file and modify the entry for the remote system to use a known user name.

BAD SEQUENCE CHECK

Explanation: The information in `/usr/lib/uucp/SQFILE` file on the local and remote system is inconsistent. Possible reasons include:

- A new `SQFILE` has been installed on either system, possibly because a new operating system release was installed.
- User Action:** Synchronize the local and remote files.
- Another system is imitating either the local or remote system. This indicates a potential security problem.

User Action: Verify that both systems are legitimate and report security issues, as necessary.

CALLBACK REQUIRED

Explanation: The local system initiated a call and informed the remote system that it has work for that system. The remote system is configured to accept work only if it initiates a call to the local system. Work is queued until the remote system calls the local system.

User Action: Monitor the queue to verify that all jobs are completed.

CALLER SCRIPT FAILED

Explanation: An error occurred while processing the chat script, defined in the `Systems` file.

User Action: Enter the `uutry remote_system` command and observe the prompts from the remote system. Compare the prompts to the chat script. If there is a difference, run the `uucpsetup` script and change the chat script.

CAN'T ACCESS DEVICE

Explanation: Possible reasons include:

- The physical device could not be opened.

User Action: Check the permissions on the terminal (tty) line, using the `ls -l` command. If neither user `uucp` nor group `uucp` has write access to the line, change the mode to `666`.

- The modem type is not defined in the `/usr/lib/uucp/Dialers` file.

User Action: Verify that the modem type has an entry in the `Dialers` file. If not, run the `uucpsetup` script and make an entry for the modem type.

CANNOT OPEN SYSTEMS FILE FOR READ

Explanation: The `uucp` program cannot read the `/usr/lib/uucp/systems` file.

User Action: Change the mode to `650`, and the owner and group to `uucp`.

CONN FAILED (*string*)

Explanation: The connection to the remote system failed; *string* describes the reason for the failure. The system will reconnect as necessary.

User Action: Monitor the queue to verify that all jobs are completed. If the problem persists, check your configuration.

CONVERSATION FAILED

Explanation: The conversation with the remote system has abnormally ended. Possible reasons are a modem error or system crash. Partially completed jobs are requeued and processed later.

User Action: Monitor the queue to verify that all jobs are completed.

DEVICE LOCKED

Explanation: Another utility (`tip`, `cu`, `uugetty`, or `uucico`) is already using the device.

User Action: Retry the request; you will continue to receive this message until the other utility has finished using the device.

DIAL FAILED

Explanation: The modem dialing sequence failed or timed out.

User Action: Retry the command.

LOGIN FAILED

Explanation: The `uucico` daemon timed out while trying to log in to the remote system.

User Action: Use the `uutry` command with your request to determine why the login is failing.

If the error occurs while processing the chat script, run the `uucpsetup` script and modify the chat script to reflect the actual messages used by the remote system. For example, if the chat script stops while waiting for a login prompt, modify the chat script to send a carriage return and delay before getting a login prompt.

If the login to the remote system is successful and then an error occurs, the `uucico` daemon on the remote system failed to start or was slow in sending the `Shere` message to the local system.

LOST LINE (LOGIN)

Explanation: The connection was lost during the login process.

User Action: Retry the request.

NO DEVICES AVAILABLE

Explanation: There are no devices available on this system of the type or speed requested.

User Action: You can install additional devices on your system, if your system allows, or modify the request to use one of the available devices in the `/usr/lib/uucp/Devices` file.

REMOTE DOES NOT KNOW ME

Explanation: The local system does not have an entry in the remote system's `Systems` file.

User Action: Contact the remote system's administrator to have an entry for your system put in the `Systems` file.

REMOTE HAS A LCK FILE FOR ME

Explanation: The remote system is trying to contact the local system while the local system is trying to connect to the remote system. The `uucp` utilities do not allow simultaneous connections between systems.

User Action: You can either retry the request later, or wait and see if the queued request is performed when the remote system connects to your system.

REMOTE REJECT AFTER LOGIN

Explanation: After successfully logging in to the remote system, the local and remote systems could not start a conversation. The remote system also returns the message `BAD LOGIN/MACHINE COMBINATION`.

User Action: Check the configuration for the connection on both systems.

REMOTE REJECT, UNKNOWN MESSAGE

Explanation: The remote system rejected the connection to the local system, but did not return a recognizable error message.

User Action: Retry your operation.

STARTUP FAILED

Explanation: After successfully logging in to the remote system, the local and remote systems could not start a conversation. Either the systems could not agree on a protocol or they could not start the protocol.

User Action: Verify that both the local and remote systems specify the same protocol in the `/usr/lib/uucp/Systems` file.

SUCCESSFUL

Explanation: The conversation completed successfully.

SYSTEM NOT IN Systems FILE

Explanation: The remote system is not in the `/usr/lib/uucp/Systems` file.

User Action: Use the `uname` command to view a list of known `uucp` systems.

TALKING

Explanation: The local system is having a conversation with the remote system.

WRONG MACHINE NAME

Explanation: The remote system name does not match the system name entry in the `/usr/lib/uucp/Systems` file.

User Action: Verify the system name and run `uucpsetup` to make the necessary changes.

WRONG TIME TO CALL

Explanation: The remote system cannot be called at this time. The job is queued for completion later.

User Action: If you want to change the time, run `uucpsetup`.

E.2 tip Error Messages

The following messages might be displayed when using the `tip` utility:

all ports busy

Explanation: All ports are in use.

User Action: Try your request again later.

can't open log file '/var/log/aculog' for update
contact your administrator

Explanation: The `/var/log/aculog` file does not exist.

User Action: Create the file with the mode 664, and owner and group `uucp`.

/etc/phones: can't open phone numbers file

Explanation: The `/etc/phones` file does not exist, or the `tip` utility cannot read the `phones` file.

User Action: Verify that the `phones` file exists and that it is not corrupted. If necessary, create a new `phones` file. See `phones(4)` for more information.

link down

Explanation: The terminal line (tty) cannot be opened.

User Action: Check that the mode of the tty device is 666.

missing phone number

Explanation: The remote system's phone number is not in the `/etc/phones` file.

User Action: Edit the `/etc/phones` file and add the remote system's phone number.

system_name: missing device spec

Explanation: The terminal line (`dv` parameter) is not defined in the `/etc/remote` file.

User Action: Edit the `/etc/remote` file and add the parameter.

tip: unknown host *sysname*

Explanation: The remote host system is not in the `/etc/remote` file.

User Action: Do one of the following:

- Create an entry for the system in the `/etc/remote` file. See `remote(4)` for more information.
- Invoke `tip` using the remote host system's phone number instead of its name.

tip: can't open host description file

Explanation: The `/etc/remote` file does not exist, or the `tip` utility cannot read the remote file.

User Action: Verify that the `remote` file exists and that it is not corrupted. If necessary, create a new `remote` file. See `remote(4)` for more information.

tip: unknown host *tipspeed*

Explanation: The `tip` utility is not configured to use the *speed* specified on the command line.

User Action: Verify whether the hardware supports the speed. If it can, create a `tipspeed` entry for the speed in the `/etc/remote` file, using other `tipspeed` entries as a model. Create corresponding `UNIX-speed` and `dialspeed` entries in the file. Specify the modem type and the serial port to which it is attached, using the `at` and `dv` fields in the `dialspeed` entry.

Unknown ACU type

Explanation: The modem is unsupported.

User Action: Check the `at` field for the host system entry in the `/etc/remote` file. If the entry is correct, create an entry for the modem in the `/etc/acucap` file. See `acucap(4)` for more information.

xxx: unknown parity value

Explanation: The parity value (pa parameter) in the `/etc/remote` file is invalid.

User Action: Edit the `/etc/remote` file and enter a valid value. See `remote(4)` for more information.

F

sendmail Error Messages

This appendix provides an explanation and suggested user actions for the sendmail error messages. These messages can occur when sending mail to another user on the same host or when sending mail using TCP/IP. If other mailers are configured on your system (for example, DECnet), see the documentation that accompanies the mailer for additional messages.

The following sendmail messages are returned in a rejected mail message or sent to the syslogd daemon:

```
binmail: opening /usr/spool/mail/filename -: Permission
denied
```

Explanation: The /bin/mail program could not deliver the mail on the destination host.

User Action:

- Verify the permissions on the /usr/spool/mail directory. The correct permissions are 1777.
- Verify the mailbox permissions. The correct permissions are 600.
- Verify that the mailbox owner is correctly specified.

```
Cannot send message for 3 days
```

Explanation: The message was not delivered during the period specified by the retry parameter in the /var/adm/sendmail/sendmail.cf file. It is being returned to the sender. Possible reasons are as follows:

- The destination host does not exist.
- The mail was addressed to a host outside of your company and no relay host has been configured in the /var/adm/sendmail/sendmail.cf file.
- The host has been off line or the network connection has been unreliable for three days.

User Action:

1. Verify all address information.

2. If the mail was addressed to a host outside of your company, you might not be able to send the mail directly. Check your `sendmail` configuration by entering the following command:

```
# grep '^define(_GateINET' /var/adm/sendmail/hostname.m4
```

If the braces in the output are empty (that is, do not contain a host name), reconfigure `sendmail` and specify a relay host. See Section 13.3 for more information on specifying a relay name.

3. Send the message again. The message is queued and sent automatically when the host is reachable.

Connection refused

Explanation: The `sendmail` daemon is not running on the destination host.

User Action: Check whether `sendmail` is running on the host by using the `ps` command as follows:

```
# ps -ax | grep send
```

If it is not, ask the system administrator to start `sendmail`.

Connection timed out during user open

Explanation: A problem occurred during the Simple Mail Transfer Protocol (SMTP) session between 2 hosts, causing a time out.

User Action: No user action is necessary; the message will be retried later.

Host unknown

Explanation: Possible reasons are as follows:

- An address record for the host was not found.
- The `/var/adm/sendmail/sendmail.cf` file does not define a relay host that can handle mail addresses outside of your company.

User Action:

1. If the Domain Name System (DNS) is not configured on your host, verify that the host's address is defined. Check the `/etc/hosts` file if you are resolving addresses locally or issue the `ypmatch hostname hosts` command if you are using the Network Information Service (NIS). The hosts entry in the `svc.conf` file defines the services used. If the host is not defined, ask your system administrator to correct the problem.
2. Check for MX records for the host by using the `nslookup` command as follows:

```
# nslookup -q=mx hostname
```

If a record exists, go to step 3.

3. Check for address records by using the `nslookup` command. If the address is not found, have the DNS administrator for the destination domain add an address record for the host in the destination domain's DNS data files.
4. If the mail was addressed to a host outside of your company, you might not be able to send the mail directly. Check your `sendmail` configuration by entering the following command:

```
# grep '^define(_GateINET' /var/adm/sendmail/hostname.m4
```

If the braces in the output are empty (that is, do not contain a host name), reconfigure `sendmail` and specify a relay host. Send the message again. See Section 13.3 for more information on specifying a relay name.

I refuse to talk to myself

Explanation: The local host was asked to connect to itself and deliver a message.

User Action: Check your `sendmail` configuration by entering the following command:

```
# grep '^define(_GateINET' /var/adm/sendmail/hostname.m4
```

If the braces on any line in the output contain your host's name, there is a configuration error. Reconfigure `sendmail`. See Section 13.3 for more information.

Remote protocol error

Explanation: This message is generally found in the `mail.log` file generated by the `syslogd` daemon and indicates a problem in communicating with the remote host.

User Action: No user action is necessary; the message will be retried later.

Service unavailable

This is a secondary error message. Some other error has occurred that caused `sendmail` to interpret an address as an action.

User Action: Look for other error messages, for example `Host unknown`, and resolve them first. Resolving other errors should resolve this error as well.

User unknown/Addressee unknown

Explanation: The message reached the final destination, but the user address was not found in the local `aliases` file or the local password file at the final destination.

User Action: Verify that the user's address is correct.

G

Host Resources MIB Implementation

The Tru64 UNIX Simple Network Management Protocol (SNMP) agent implements the Host Resources MIB as described in RFC 1514. Although the RFC describes conceptual objects for management of host systems, it describes them in very general terms.

This appendix describes the Tru64 UNIX Host MIB implementation, including each group or table defined in RFC 1514 (with sample data). The formatting of SNMP data is specific to the implementation of an application. Compaq currently does not ship an application that presents SNMP data in this manner with Tru64 UNIX.

G.1 Tru64 UNIX Implementation Summary

The basic Tru64 UNIX implementation of RFC 1514 is as follows:

- The RFC specifies that when a product registry does not exist, all MIB variables of type `ProductID` return an object identifier of 0.0.
- The values of the `hrDeviceIndex` and `hrFSIndex` parameters remain unique between system reboots.
- Write access is not implemented for any Host MIB object.

G.2 System Group

The system group object implementation notes are as follows:

- The `hrSystemInitialLoadDevice` parameter is not implemented.
- The `hrSystemInitialLoadParameters` parameter returns the name of the booted kernel.

The following are sample data:

```
{hrSystemUptime.0           , TimeTicks, 0d 23:00:20.00}
{hrSystemDate.0            , OCTET STRING, 1995-11-28,15:31:52.01}
{hrSystemInitialLoadParameters.0 , OCTET STRING, vmunix}
{hrSystemNumUsers.0        , Gauge, 0}
{hrSystemProcesses.0       , Gauge, 20}
{hrSystemMaxProcesses.0    , INTEGER, 1024}
```

G.3 Storage Group

The operating system software represents three types of logical storage: swap space, kernel memory, and file systems. The storage group object implementation is as follows:

- One entry in the `hrStorageTable` group is the total kernel memory being used.
- One entry is the current total swap space. (The value of the `hrStorageAllocationFailures` parameter for this entry is always 0.)
- There are several entries that each describe a specific type of kernel memory (the kernel malloc table). There is an entry for each memory type listed in the `<sys/malloc.h>` header file that is implemented on that particular host. (The value of the `hrStorageDescr` parameter is derived from the `malloc.h` file.)

Note

These entries do not represent actual fixed-size memory pools that could be exhausted. They do, however, indicate how system memory is being utilized amongst the various subsystems.

The value of the `hrStorageSize` parameter for the kernel memory entries is always 0, because there is no actual limit.

- There is one entry in the `hrStorageTable` group for each locally mounted file system. As specified in RFC 1514, remotely mounted file systems are not represented in the `hrStorageTable` group.
- The value of the `hrStorageDescr` parameter for file system-related entries is the same as the `hrFSMountedPoint` parameter for the same file system in the `hrFSSTable` group.
- The values of the `hrStorageIndex` parameter for file system-related entries is returned in the `hrFSStorageIndex` variable for the same file system in the `hrFSSTable` group.
- The value of the `hrStorageType` parameter for file system storage entries is always `hrStorageOther`.

See Section G.5 for information on the file system implementation.

The following are sample storage group data:

```
{hrStorageIndex.1           , INTEGER, 1}
{hrStorageType.1          , OBJECT IDENTIFIER, hrStorageRam}
{hrStorageDescr.1         , OCTET STRING, Total Kernel Memory}
{hrStorageAllocationUnits.1 , INTEGER, 1024}
{hrStorageSize.1          , INTEGER, 2088960}
{hrStorageUsed.1          , INTEGER, 261112}
```

```

{hrStorageAllocationFailures.1 , Counter, 0}
{hrStorageIndex.2 , INTEGER, 2}
{hrStorageType.2 , OBJECT IDENTIFIER, hrStorageVirtualMemory}
{hrStorageDescr.2 , OCTET STRING, Total Swap Space}
{hrStorageAllocationUnits.2 , INTEGER, 1024}
{hrStorageSize.2 , INTEGER, 200704}
{hrStorageUsed.2 , INTEGER, 11920}
{hrStorageAllocationFailures.2 , Counter, 0}
{hrStorageIndex.3 , INTEGER, 3}
{hrStorageType.3 , OBJECT IDENTIFIER, hrStorageRam}
{hrStorageDescr.3 , OCTET STRING, MBUF}
{hrStorageAllocationUnits.3 , INTEGER, 1}
{hrStorageSize.3 , INTEGER, 0}
{hrStorageUsed.3 , INTEGER, 4096}
{hrStorageAllocationFailures.3 , Counter, 0}
{hrStorageIndex.4 , INTEGER, 4}
{hrStorageType.4 , OBJECT IDENTIFIER, hrStorageRam}
{hrStorageDescr.4 , OCTET STRING, MCLUSTER}
{hrStorageAllocationUnits.4 , INTEGER, 1}
{hrStorageSize.4 , INTEGER, 0}
{hrStorageUsed.4 , INTEGER, 32768}
{hrStorageAllocationFailures.4 , Counter, 0}
:
:
{hrStorageIndex.99 , INTEGER, 99}
{hrStorageType.99 , OBJECT IDENTIFIER, hrStorageOther}
{hrStorageDescr.99 , OCTET STRING, /}
{hrStorageAllocationUnits.99 , INTEGER, 1024}
{hrStorageSize.99 , INTEGER, 63167}
{hrStorageUsed.99 , INTEGER, 46098}
{hrStorageAllocationFailures.99 , Counter, 0}
{hrStorageIndex.100 , INTEGER, 100}
{hrStorageType.100 , OBJECT IDENTIFIER, hrStorageOther}
{hrStorageDescr.100 , OCTET STRING, /proc}
{hrStorageAllocationUnits.100 , INTEGER, 8192}
{hrStorageSize.100 , INTEGER, 0}
{hrStorageUsed.100 , INTEGER, 0}
{hrStorageAllocationFailures.100 , Counter, 0}
{hrStorageIndex.101 , INTEGER, 101}
{hrStorageType.101 , OBJECT IDENTIFIER, hrStorageOther}
{hrStorageDescr.101 , OCTET STRING, /usr}
{hrStorageAllocationUnits.101 , INTEGER, 1024}
{hrStorageSize.101 , INTEGER, 866102}
{hrStorageUsed.101 , INTEGER, 596323}
{hrStorageAllocationFailures.101 , Counter, 0}

```

G.4 Device Tables

This implementation supports CPUs, network interfaces, and disks in the device-related tables; printers are not supported. The CPU support is as follows:

- Each CPU physically attached to the system is represented in both the `hrDevice` and `hrProcessor` tables. The value of the `hrDeviceIndex` parameter for these entries is the processor number plus 1.
- The value of the `hrDeviceErrors` parameter is always 0.
- The value of the `hrDeviceStatus` parameter is either `running` or `down`.

- The value of the `hrProcessorLoad` parameter is accurately determined for each processor running on the system. Processor idle time is any time spent in the IDLE or WAIT states. Busy time is time spent in any other state.

A background task records CPU time every 30 seconds, retaining 2 snapshots. When an SNMP request is received, CPU times are fetched immediately and the load average is calculated as the difference between this current data and the least recent snapshot. In this manner the values returned for the `hrProcessorLoad` parameter are current load averages over a period of at least 30 seconds, but not more than 1 minute. The value of the `hrProcessorLoad` parameter is calculated as follows:

$$(\text{delta } \textit{busy} / (\text{delta } \textit{busy} + \text{delta } \textit{idle})) * 100$$

The disk support is as follows:

- Each `re`, `ra`, and `rz` type disk whose special file is present in the `/dev` directory is represented in the `hrDeviceTable` group, the `hrDiskStorageTable` group, and the `hrPartitionTable` group.
- The value of the `hrDeviceStatus` parameter is `running` if the disk is online, or `down` if the disk is offline.
- The value of the `hrDeviceErrors` parameter is the sum of hard and soft errors reported for the disk.
- The value of the `hrDiskStorageMedia` parameter is always `unknown`.
- Data cannot be retrieved currently for offline devices (for instance, an empty CD-ROM drive). In these cases, the `hrDiskStorage` entry is as follows:

```
media = 'unknown'
capacity = 0
removable = 'false'
access = 'readWrite'
```

The value of the `hrPartitionFSIndex` parameter is either zero (0) or the value of the `hrFSIndex` parameter for the `hrFS`Table entry corresponding to the offline file system.

The network device support is as follows:

- Each network interface is represented in both the `hrDeviceTable` group and `hrNetworkTable` group.
- The value of the `hrDeviceStatus` parameter is `running` if the interface is running, `down` if the interface is not up, or `unknown`.
- The value of the `hrDeviceErrors` parameter is the sum of inbound and outbound packet errors on that interface.

- The value of the hrNetworkIfIndex parameter is the same as the MIB-II value of the ifIndex parameter for that interface.

The following are sample device table data:

```

{hrDeviceIndex.1           , INTEGER, 1}
{hrDeviceType.1           , OBJECT IDENTIFIER, hrDeviceProcessor}
{hrDeviceDescr.1          , OCTET STRING, Digital 2100 Server Model A500MP}
{hrDeviceID.1             , OBJECT IDENTIFIER, 0.0}
{hrDeviceStatus.1         , INTEGER, running}
{hrDeviceErrors.1         , Counter, 0}
{hrDeviceIndex.2          , INTEGER, 2}
{hrDeviceType.2           , OBJECT IDENTIFIER, hrDeviceProcessor}
{hrDeviceDescr.2          , OCTET STRING, Digital 2100 Server Model A500MP}
{hrDeviceID.2             , OBJECT IDENTIFIER, 0.0}
{hrDeviceStatus.2         , INTEGER, running}
{hrDeviceErrors.2         , Counter, 0}
{hrDeviceIndex.3          , INTEGER, 3}
{hrDeviceType.3           , OBJECT IDENTIFIER, hrDeviceProcessor}
{hrDeviceDescr.3          , OCTET STRING, Digital 2100 Server Model A500MP}
{hrDeviceID.3             , OBJECT IDENTIFIER, 0.0}
{hrDeviceStatus.3         , INTEGER, running}
{hrDeviceErrors.3         , Counter, 0}
{hrDeviceIndex.4          , INTEGER, 4}
{hrDeviceType.4           , OBJECT IDENTIFIER, hrDeviceProcessor}
{hrDeviceDescr.4          , OCTET STRING, Digital 2100 Server Model A500MP}
{hrDeviceID.4             , OBJECT IDENTIFIER, 0.0}
{hrDeviceStatus.4         , INTEGER, running}
{hrDeviceErrors.4         , Counter, 0}
{hrDeviceIndex.5          , INTEGER, 5}
{hrDeviceType.5           , OBJECT IDENTIFIER, hrDeviceNetwork}
{hrDeviceDescr.5          , OCTET STRING, tu0 - DEC TULIP Ethernet Interface}

```

G.5 File System Table

The file system table implementation is as follows:

- Each currently mounted file system is represented in the `hrFSSTable` group.
- The available values for the `hrFSSType` parameter do not cover all possible file system types in the operating system. Some types (for example, `/proc`) report a value of `hrFSOther` for the `hrFSSType` object.
- The `hrFSRemoteMountPoint` parameter is returned as a zero-length octet string for local file systems, as specified in RFC 1514.
- The `hrFSStorageIndex` parameter returns a zero (0) for remote file systems, in accordance with RFC 1514. For local file systems, the `hrFSStorageIndex` parameter returns the value of the `hrStorageIndex` parameter for the `hrStorageEntry` entry corresponding to that file system.

The RFC specifies this design, presumably so that all storage-related information is available in one table. However, in order to discover file system full conditions, an SNMP application needs to do the following:

1. Locate an entry in the the `hrFSSTable` group.
 2. Retrieve that entry's value of the `hrFSStorageIndex` parameter. For example, call it *i*.
 3. If *i* is not zero (0), retrieve the values of the `hrStorageUsed.i` and `hrStorageSize.i` parameters.
- The value of the `hrFSBootable` parameter is always returned as `false`.
 - The values of the `hrFSLastFullBackupDate` and `hrFSLastPartialBackupDate` parameters are always returned as {January 1 year 0 time 0}, in the `DateAndTime` format, as specified in RFC 1514, when these values are unknown.

The following are sample file system table data:

```
{hrFSIndex.1 , INTEGER, 1}
{hrFSMountPoint.1 , OCTET STRING, /}
{hrFSRemoteMountPoint.1 , OCTET STRING, }
{hrFSSType.1 , OBJECT IDENTIFIER, hrFSBerkeleyFFS}
{hrFSAccess.1 , INTEGER, readWrite}
{hrFSBootable.1 , INTEGER, false}
{hrFSStorageIndex.1 , INTEGER, 99}
{hrFSLastFullBackupDate.1 , OCTET STRING, 0-1-1,0:0:0.0}
{hrFSLastPartialBackupDate.1 , OCTET STRING, 0-1-1,0:0:0.0}
{hrFSIndex.2 , INTEGER, 2}
{hrFSMountPoint.2 , OCTET STRING, /proc}
{hrFSRemoteMountPoint.2 , OCTET STRING, }
{hrFSSType.2 , OBJECT IDENTIFIER, hrFSOther}
{hrFSAccess.2 , INTEGER, readWrite}
{hrFSBootable.2 , INTEGER, false}
{hrFSStorageIndex.2 , INTEGER, 100}
```

```

{hrFSLastFullBackupDate.2      , OCTET STRING, 0-1-1,0:0:0.0}
{hrFSLastPartialBackupDate.2  , OCTET STRING, 0-1-1,0:0:0.0}
{hrFSIndex.3                   , INTEGER, 3}
{hrFSMountPoint.3              , OCTET STRING, /usr}
{hrFSRemoteMountPoint.3       , OCTET STRING, }
{hrFSType.3                    , OBJECT IDENTIFIER, hrFSBerkeleyFFS}
{hrFSAccess.3                  , INTEGER, readWrite}
{hrFSBootable.3                , INTEGER, false}
{hrFSStorageIndex.3           , INTEGER, 101}
{hrFSLastFullBackupDate.3     , OCTET STRING, 0-1-1,0:0:0.0}
{hrFSLastPartialBackupDate.3  , OCTET STRING, 0-1-1,0:0:0.0}
{hrFSIndex.4                   , INTEGER, 4}
{hrFSMountPoint.4              , OCTET STRING, /tools}
{hrFSRemoteMountPoint.4       , OCTET STRING, /tools@tools}
{hrFSType.4                    , OBJECT IDENTIFIER, hrFSNFS}
{hrFSAccess.4                  , INTEGER, readWrite}
{hrFSBootable.4                , INTEGER, false}
{hrFSStorageIndex.4           , INTEGER, 0}
{hrFSLastFullBackupDate.4     , OCTET STRING, 0-1-1,0:0:0.0}
{hrFSLastPartialBackupDate.4  , OCTET STRING, 0-1-1,0:0:0.0}

```

G.6 Running Software Tables

The running software table implementation is as follows:

- The `hrSWOSIndex` parameter is always returned as zero (0), the kernel idle process. There is no one process that represents the primary operating system running on this host for Tru64 UNIX.
- Each process is represented as an entry in both the `hrSWRunTable` group and the `hrSWRunPerfTable` group. The value of the `hrSWRunIndex` parameter (used to index both tables) is the pid of that process. This means there is an entry whose `hrSWRunIndex` parameter value is 0 (zero), which is not typical of SNMP tables.
- The `hrSWRunName` parameter is always returned as a zero-length octet string.
- The `hrSWRunType` parameter is always returned as unknown.
- The `hrSWRunStatus` parameter is returned as either running (processes that are capable of being run or are waiting for CPU), or `notrunnable` (stopped or waiting for non-CPU resources).
- The `hrSWRunPath` parameter and the `hrSWRunParameters` parameter return the command and parameters, respectively, that were used to start this process. This is similar, but not identical, to the output of the `ps` command.
- The `hrSWRunPerfCPU` parameter returns the sum of accumulated system and user time for all threads running in a process. This value is equivalent to the value returned by the `ps cputime` specifier (adjusted to units of centiseconds).
- The `hrSWRunPerfMem` parameter returns the current resident set size of the process. This value is equivalent to the value returned by the `ps`

rssize specifier, adjusted to units of 1024 bytes (a "Kbyte" as defined in RFC 1514).

The following are sample running software table data:

```

{hrSWRunIndex.0           , INTEGER, 0}
{hrSWRunName.0           , OCTET STRING, }

Format of DNS Data File Entries

The Domain Name System (DNS) configuration file, by default called `/etc/namedb/named.conf`, specifies the names of the DNS data files. These data files consist of entries, also known as Resource Records (RR), that follow the formats described in this chapter.

H.1 Format of DNS Resource Records

Here is the general format of a DNS Resource Record:

name ttl addr-class entry-type entry-specific-data

The fields are defined as follows:

Field	Description
<i>name</i>	<p>This is the name of the domain, for example <code>cities.dec.com</code>. The domain name must begin in the first column.</p> <p>For some data file entries the name field is left blank. In that case, the domain name is assumed to be the same as the previous entry.</p> <p>A free standing period (<code>.</code>) refers to the current domain.</p> <p>A free standing at sign (<code>@</code>) denotes the current origin, thus allowing you to specify more than one domain.</p> <p>Two free standing periods (<code>..</code>) represent the null domain name of the root.</p>
<i>ttl</i>	<p>This is the time-to-live field, and specifies how long, in seconds, the data will be stored in the database. If this field is left blank, the value defaults to the <code>ttl</code> value specified in the SOA (start of authority) entry or, ultimately, the value of the <code>\$ttl</code> entry. The maximum time-to-live is 99999999 seconds, or 3 years.</p>

Field	Description
<i>addr-class</i>	This field is the address class. There are three classes: IN — Internet addresses, TXT — naming service data, ANY — all other types of network addresses. The address class of all data file entries of a given entry-type in a particular zone must be the same. Therefore, only the first entry in a zone need specify the <i>addr-class</i> field.
<i>entry-type</i>	This field states the resource record type, for example SOA (start of authority) or A (address).
<i>entry-specific-data</i>	All fields after the entry-type field vary for each type of data file entry (resource record).

The case is preserved in name and data fields when loaded into the DNS server. Comparisons and lookups using the DNS are case insensitive.

The following characters have special meanings in DNS data file entries:

Character	Meaning
<code>\x</code>	A backslash (\) escapes the next nondigit (x) character so that the character's special meaning does not apply. For example, you could use a period (.) to place a period character in a label.
<code>\nnn</code>	A backslash denotes the octet corresponding to the decimal number represented by nnn. The resulting octet is assumed to be text and is not checked for special meaning.
<code>()</code>	Parentheses group data that cross a line. In effect, line terminations are not recognized within parentheses.
<code>;</code>	A semicolon starts a comment, causing the rest of the line to be ignored.
<code>*</code>	An asterisk signifies a wildcard.

Most DNS data file entries have the current domain appended to their names if they are not terminated by a period (.). This is useful for appending the current domain name to the data, such as system names, but could cause problems when you do not want this to happen. Consequently, if the name is not in the domain for which you are creating the data file, end the name with a period.

Data files (resource records) can have the following types of entries:

- `$include`
- `$origin`

- \$ttl — time to live
- A — address
- CNAME — canonical name
- HINFO — host information
- MB — mail box
- MG — mail group
- MINFO — mailbox information
- MR — mail rename
- MX — mail exchanger
- NS — name server
- PTR — domain name pointer
- SOA — start of authority
- WKS — well known services

H.2 Description of Data File Entries

The following sections describe each data file entry and its format.

H.2.1 Include Entry

An include entry is similar to a header file in the C programming language. This feature is particularly useful for separating different types of data into multiple files. An include entry begins with `$include` in the first column, and is followed by the name of the file to be included. For example:

```
$include /etc/namedb/mailboxes
```

This entry requests the DNS to load the data file `/etc/namedb/mailboxes`.

The include entry loads data files into the local zone and acts as a data file organizer. For example, you can use `$include` entries to separate mail from host information.

H.2.2 Origin Entry

An origin entry changes the origin in a data file. This feature is particularly useful for putting more than one domain in a data file. An origin entry begins with `$origin` in the first column, followed by a domain origin, as shown in the following example:

```
$origin state.dec.com.
```

This entry includes the domain `state.dec.com` in the data file. As a result, the DNS can provide information about the `state.dec.com` domain in addition to the local domain, provided your server has authority for the zone.

The `$origin` and `$include` entries can work together. They can save typing and help keep the files organized. For example, assume that the following entries are in the `hosts.rev` file:

```
$origin 11.128.in-addr.arpa.  
$include cities.dec.com.rev
```

The period after `arpa` signifies the complete domain name. Assume that the `cities.dec.com.rev` file consists of entries similar to the following:

```
33.22 IN PTR chicago.cities.dec.com.
```

In this situation, the complete reverse name for the host `chicago` is translated to be as follows:

```
33.22.11.128. in-addr.arpa. IN PTR chicago.cities.dec.com.
```

H.2.3 TTL Entry

The time-to-live entry is similar to the `ttl` field in other resource records; it specifies how long data will be stored in the cache. However, when you set the time-to-live in the optional `$ttl` entry, the limit takes effect only if no time-to-live value is specified for a particular resource record or its corresponding SOA record.

A `$ttl` entry begins with `$ttl` in the first column, a value in the second column, and an optional comment in the third column. For example, this entry specifies that resource records without a specified `ttl` will expire after 21600 seconds (or six hours):

```
$ttl 21600 default time to live
```

When you specify it in this manner, the time-to-live value must be in the range of 0 to 2147483647 seconds. Alternatively, you can specify the time-to-live in the following format, where you need not specify all of the fields:

```
weeksWdaysDhoursHminutesMsecondsS
```

For example, the maximum value in this format (3550 weeks, 5 days, 3 hours, 14 minutes, 7 seconds) would be specified as follows:

```
$ttl 3550W5D3H14M7S
```

H.2.4 Address Entry

The address (A) data file entry lists the address for a specific system. An A entry has the following format:

name ttl addr-class entry-type address

The fields in the A entry have the values described in Section H.1, with the exception of the *address* field. This field specifies the IP address for each system. There must be only one A entry for each address on a given system.

The following is an example of two A entries:

```
;name          ttl    addr-class  entry-type  address
miaml.cities.dec.com.      IN      A           A           128.11.22.44
                        IN      A           A           128.11.22.33
```

In this example, note that in the first entry the *ttl* field is blank, thus using the default *ttl* specified in the SOA entry. In the second entry, the first and second fields are blank, thus using the default name specified in the previous entry and the default *ttl* specified in the SOA entry. In this example, the host *miami.cities.dec.com* has two IP addresses.

H.2.5 Canonical Name Entry

The canonical name (CNAME) entry specifies an alias for a canonical name. For example, if the canonical name, (also known as the full DNS name or the fully qualified name) is *miami.cities.dec.com*, a reasonable alias might be *miami* or *mi*.

An alias must be unique, and all other entries must be associated with the canonical name and not with the alias. Do not create an alias and then use it in other entries. A CNAME entry has the following format:

aliases ttl addr-class entry-type can-name

The fields in the CNAME entry have the values described in Section H.1, with the following exceptions:

Field	Description
<i>alias</i>	This field specifies the nickname (alias) of the canonical name of the host.
<i>can-name</i>	This is the canonical name of the host. If the canonical name is a part of the current domain, you need to specify only the host name, for example, <i>miami</i> . If the canonical name is for a host in another domain, you must specify the fully qualified DNS name, followed by a period (.). For example: <i>ohio.state.dec.com</i> .

The following example shows two CNAME entries. The first entry is for a CNAME in the current domain, *cities.dec.com*; the second entry is for a CNAME in another domain:

```
;aliases      ttl    addr-class  entry-type  can-name
to           IN      CNAME      CNAME      toledo
```

```
oh                IN                CNAME                ohio.state.dec.com.
```

H.2.6 Host Information Entry

The host information (HINFO) data file entry is for host specific information. This entry lists the hardware and operating system that are running at the specified host system. Only a single space separates the name of the hardware from the operating system information. Thus, if you need to use spaces as part of a host or operating system name, you must place the name in quotation marks. In addition, there can be no more than one HINFO entry for each host on the domain. The following is the HINFO entry format:

```
host ttl addr-class entry-type hardware opsys
```

The fields in the HINFO entry have the values described in Section H.1, with the following exceptions:

Field	Description
<i>host</i>	This field specifies the host name. If the host is in the current domain, you need to specify only the host, for example, <i>chicago</i> . If the host is in a different domain, you must specify the full DNS name, for example, <i>utah.state.dec.com.</i> . Be sure to include the period (.) at the end of the host name. This indicates the fully qualified DNS name.
<i>hardware</i>	This field specifies the type of CPU, for example, an AlphaServer 8400.
<i>opsys</i>	This field specifies the type of operating system running on the specified host. Its recommended setting is Tru64 UNIX for the Tru64 UNIX operating system.

The following is an example of a HINFO entry:

```
;name                ttl  addr-class  entry-type  hardware                opsys
ohio.state.dec.com.  IN                HINFO        "AlphaServer
8400"  "Tru64 UNIX"
```

In this example, note that the second field specifying the *ttl* is blank, thus using the default *ttl* specified in the SOA entry.

H.2.7 Mailbox Entry

The mailbox (MB) entry lists the system where a user wants to receive mail. The following is the format of an MB entry:

```
login ttl addr-class entry-type system
```

The fields in the MB entry have the values described in Section H.1, with the following exceptions:

Field	Description
<i>login</i>	This field is the login name for a user. Login names must be unique for the domain.
<i>system</i>	This field specifies the name system where the user wants to receive mail.

The following is an example of an MB entry:

```
;login    ttl    addr-class  entry-type  system
fred      blank IN          MB          potsdam.cities.dec.com.
```

In this example, note that the second field is blank, thus using the ttl specified in the SOA entry. Consequently, the user Fred will have mail delivered to the host named potsdam in the domain cities.dec.com.

H.2.8 Mail Group Entry

The mail group (MG) entry specifies the members of a mail group. The MG entry is usually used with a MINFO entry. The following is the format of an MG entry:

```
group ttl addr-class entry-type member
```

The fields in the MG entry have the values described in Section H.1, with the following exceptions:

Field	Description
<i>group</i>	This field specifies the name of the mail group, for example, users or marketing.
<i>member</i>	This field specifies the login name and the domain of the user to be included in the mail group.

The following is an example of a MINFO entry and several MG entries:

```
;group    ttl    addr-class  entry-type  requests  member
fun       blank IN          MINFO      BIND-REQUEST  fred@miami.cities.dec.com.
          blank IN          MG         john@miami.cities.dec.com.
amy@miami.cities.dec.com.
          blank IN          MG
```

In this example, note that the second field for all three entries is blank, thus using the ttl specified in the SOA entry. In addition, Fred, John, and Amy will receive any mail sent to the mail group fun.

H.2.9 Mailbox Information Entry

The mailbox information (MINFO) entry creates a mail group for a mailing list. The MINFO entry is usually associated with a mail group (MG) entry, but can also be used with a mailbox (MB) entry. The following is the format of a MINFO entry:

mailbox ttl addr-class entry-type requests maintainer

The fields in the MINFO entry have the values described in Section H.1, with the following exceptions:

Field	Description
<i>mailbox</i>	This field specifies the name of the mailbox, and its value is usually BIND.
<i>requests</i>	This field specifies the name where users can send mail relating to the DNS or mail. For example, a user might want to send a mail message requesting that an alias be set up.
<i>maintainer</i>	This field contains the login name of the person who will receive mail error messages. This is particularly useful when an error in member's names needs to be reported to a person other than the sender.

The following is an example of a MINFO entry:

```
mailbox    ttl    addr-class  entry-type  requests    maintainer
BIND                               IN          MINFO       BIND-REQUEST
fred@miami.cities.dec.com.
```

In this example, note that the second field is blank, thus using the *ttl* specified in the SOA entry.

H.2.10 Mail Rename Entry

The mail rename (MR) entry lists aliases for a specific user. The following is the format of an MR entry:

alias ttl addr-class entry-type login

The fields in the MR entry have the values described in Section H.1, with the following exceptions:

Field	Description
<i>alias</i>	This field lists the nicknames for the specified user. The alias must be unique to the domain.
<i>login</i>	This field is the login name for the user whose alias is being established. There should also be a corresponding MB entry for the specified login name. Login names must be unique for the domain.

The following is an example of an MR entry:

```
;alias    ttl    addr-class  entry-type  login
lady      IN          MR          diana
```

```
princess      IN      MR      diana
```

This example shows how to set up the aliases lady and princess for a user whose login name is diana. Note that the second field is left blank, thus using the ttl specified in the SOA entry.

H.2.11 Mail Exchanger Entry

The mail exchanger (MX) entry specifies a system in the local domain (called a gateway) that knows how to deliver mail to a system that may not be directly connected to the local network. Consequently, the MX entry is useful for systems outside your local network that want to send mail to a user on one of your network's hosts.

You can also use the MX entry to list some of the hosts in the `/etc/hosts` file so that they do not appear to other systems using the DNS service.

The following is the format of an MX entry:

```
system ttl addr-class entry-type pref-value gateway
```

The fields in the MX entry have the values described in Section H.1, with the following exceptions:

Field	Description
<i>system</i>	This field specifies the name of the system where mail is to be sent.
<i>pref-value</i>	This field specifies the order a mailer is to follow when there is more than one way to deliver mail to a given system.
<i>gateway</i>	This field contains the name of the gateway system, that is, the system that can deliver mail to the destination system on another network.

The following is an example of two MX entries:

```
;system      ttl      addr-class  entry-type  pref-value  gateway
tampa.cities.dec.com      IN      MX      0      seismo.cs.au.
*.folks.dec.com      IN      MX      0      relay.cs.net.
```

In this example, all mail destined for the domain `folks.dec.com`, regardless of the host name, is sent by route of the `relay.cs.net` host. In addition, note that the second field in both entries is blank, thus using the ttl specified in the SOA entry. The second entry uses an asterisk, which is a wildcard.

H.2.12 Name Server Entry

The name server (NS) entry specifies that a system is a name server for the specified domain. The following is the format of the NS entry:

name ttl addr-class entry-type server

The fields in the NS entry have the values described in Section H.1, with the exception of the *server* field. This field specifies the name of the primary master server for the domain specified in the first field.

The following is an example of an NS entry:

```
;name      ttl      addr-class  entry-type  server
           IN              NS          utah.states.dec.com.
```

H.2.13 Domain Name Pointer Entry

The domain name pointer (PTR) entry allows special names to point to some other location in the domain. PTR names must be unique to the zone. These entries are located on a primary server in the file `/etc/namedb/hosts.rev`. The following is the format of a PTR entry:

rev-addr ttl addr-class entry-type hostname

The fields in the PTR entry have the values described in Section H.1, with the following exceptions:

Field	Description
<i>rev-addr</i>	This field specifies the reverse IP address of the host. For example, if the host's address is 128.11.22.33, the reverse address is 33.22.11.128.
<i>hostname</i>	This is the fully qualified DNS name of the host, for example, <code>miami.cities.dec.com</code> . Be sure to include the period (.) at the end of the host name if the host is not in the current domain.

The following is an example of two PTR entries:

```
;rev-addr          ttl      addr-class  entry-type  hostname
33.22              IN              PTR         chicago
66.55.44.121.in-addr.arpa.  IN              PTR         mail.peace.org.
```

In this example, the first entry is for a host whose IP host address is 22.33 in the current domain. The specified `rev.addr` (33.22) is meaningful assuming that a `$origin` entry exists. See Section H.2.2 for a description of the `$origin` entry. If there is not an `$origin` entry, then the entire IP address, in reverse, must be specified.

The second entry is for a host in different domain (`mail.peace.org`). As a rule, do not do this because you are putting data in your server's cache for which your server is not authoritative. PTR entries and other resource records are for hosts in your domain only. The PTR entry sets up a reverse pointer for the host `mail.peace.org`.

H.2.14 Start of Authority Entry

The start of authority (SOA) entry designates the beginning of a zone. There can be no more than one SOA entry per zone. The following is the format of an SOA entry:

```
name ttl addr-class entry-type origin person serial# refresh retry\  
expire min
```

The forward slash (\) indicates line continuation.

The fields in the SOA entry have the values described in Section H.1, with the following exceptions:

Field	Description
<i>origin</i>	This field is the name of the host on which the data file resides. This is usually a master server.
<i>person</i>	This field defines the login name and mailing address of the person responsible for the DNS running on the local domain.
<i>serial#</i>	<p>This field specifies the version number of the data file. The person editing the master files for the zone must increment the value in this field each time a change is made to the data within the file. The serial number being changed informs the secondary servers that there is new data to be obtained from the master server. The maximum number is $2^{32}-1$ after the decimal point.</p> <p>The serial number field allows the DNS to determine which of two copies of data files in a zone are more recent. Typically, the serial number field begins at one (1) and is incremented by one each time the original data file is modified. It is best to use whole integers.</p>
<i>refresh</i>	<p>This field specifies how often, in seconds, a secondary DNS server is to check with the master server to see if it needs to update its data files. If the data files are out of date (as indicated by a mismatch of serial number fields), they are updated with the contents of the master server's files.</p> <p>The minimum refresh period is 30 seconds. If the refresh field is blank, however, the data file is not dynamically updated.</p>

Field	Description
<i>retry</i>	This field specifies how often, in seconds, a secondary DNS server will try to refresh its data files after a refresh failure has occurred while making the check. If a DNS server attempts to refresh the files and fails, it tries to refresh them again every so many seconds, as specified in the <i>retry</i> field.
<i>expire</i>	This field specifies the upper limit, in seconds, that a secondary DNS server can use the data files in its cache before the data expires for lack of being updated, or before the DNS server checks to see if its cache needs to be updated.
<i>min</i>	This field specifies the default time to live, in seconds, that a data entry can exist in the event that the <i>ttd</i> entry is left blank.

The following is an example of an SOA entry. The first line is a comment that shows the fields:

```

;name    ttl    addr-class  entry-type  origin                                person
@                IN          SOA         utah.states.dec.com. hes.utah.states.dec.com. (
                                1          ; serial
                                3600         ; refresh every hr.
                                300          ; retry every 5 min.
                                3600000      ; expire in 1000 hrs.
                                86400 ) ; min. life is 24 hrs.

```

In this example note that the parentheses indicate to the DNS that this is a single entry. The *ttd* field is blank, indicating that the default time to live specified in the *min* field (86400 seconds) is being used.

The semicolons allow comments for readability. In the example, the serial field is 1, the refresh field is 3600 seconds (once per hour), the *retry* field is 300 seconds (once per 5 minutes), the *expire* field is 3,600,000 seconds (1000 hours), and the *min* field is 86400 seconds (24 hours).

H.2.15 Well Known Services Entry

The well known services (WKS) entry describes well known services supported by a particular protocol at a specified address. The services and port numbers are obtained from the list of services specified in the */etc/services* file. The following is the format of a WKS entry:

```
name ttl addr-class entry-type address protocol services
```

The fields in the WKS entry have the values described in Section H.1, with the following exceptions:

Field	Description
<i>address</i>	This field specifies the IP address for each system. There can be only one WKS entry for each protocol at each address.
<i>protocol</i>	This field specifies the protocol to be used, for example TCP or UDP.

Here is an example of two WKS entries:

```

;name      ttl      addr-class  entry-type  address      protocol  services
          IN          WKS         128.32.0.4  UDP          who route
          IN          WKS         128.32.0.78 TCP          (echo talk
                                discard sunrpc sftp
                                uucp-path netstat host
                                systat daytime link
                                auth time ftp
                                nntp whois pop
                                finger smtp supdup
                                domain nameserver
                                chargen)

```

Note that the first and second fields of both entries in this example are blank, which indicates that they are using the domain name specified in a previous entry and the default ttl specified in the SOA entry. The services listed in the second entry are contained within parentheses and are thus interpreted as being one entry, even though they appear to be on several lines.

- troubleshooting, 15-53
- uused command, 11-23
- uucpsetup command, 11-12
- uudemon.admin script, 11-17
 - monitoring uucp status, 11-17
 - running, 11-18
- uudemon.cleantu script, 11-20

- and log files, 11-22
- and uucleanup command, 11-20
- running, 11-20
- uudemon.hour script, 11-23
 - and uudemon.poll script, 11-25
 - running, 11-24
- uudemon.poll script, 11-25
 - and uudemon.hour script, 11-25
- uulog command, 11-22
- uused command, 11-23
- uustat command, 11-17
- uutry command, 16-7
- uuxqt
 - limiting number of processes, 11-23

V

- variables
 - environment, B-6
- VC
 - accounting for ATM adapter, 4-9
 - monitoring, 4-26
- VCI
 - specifying for PVC, 4-11
- virtual channel identifier
 - (*See* VCI)
- virtual circuit
 - (*See* VC)
- virtual path identifier
 - (*See* VPI)
- VPI
 - specifying for PVC, 4-11

W

- well-known multicast addresses, 3-8
- whois command, 8-32
- whois service
 - using, 8-32

X

xjoin command, 5–12
xntpd daemon, 12–1
 (*See also* NTP)
 and system security, 12–7
 monitoring hosts, 12–8
xntpd command, 12–9

(*See* NIS)

ypcat command, 9–31
ypmatch command, 9–31
yppasswd command, 9–31
ypservers map
 showing contents of, 9–22
ypwhich command, 9–31

How to Order Tru64 UNIX Documentation

To order Tru64 UNIX documentation in the United States and Canada, call **800-344-4825**. In other countries, contact your local Compaq subsidiary.

If you have access to Compaq's intranet, you can place an order at the following Web site:

<http://asmorder.nqo.dec.com/>

If you need help deciding which documentation best meets your needs, see the Tru64 UNIX *Documentation Overview*, which describes the structure and organization of the Tru64 UNIX documentation and provides brief overviews of each document.

The following table provides the order numbers for the Tru64 UNIX operating system documentation kits. For additional information about ordering this and related documentation, see the *Documentation Overview* or contact Compaq.

Name	Order Number
Tru64 UNIX Documentation CD-ROM	QA-6ADAA-G8
Tru64 UNIX Documentation Kit	QA-6ADAA-GZ
End User Documentation Kit	QA-6ADAB-GZ
Startup Documentation Kit	QA-6ADAC-GZ
General User Documentation Kit	QA-6ADAD-GZ
System and Network Management Documentation Kit	QA-6ADAE-GZ
Developer's Documentation Kit	QA-6ADAF-GZ
Reference Pages Documentation Kit	QA-6ADAG-GZ
TruCluster Server Documentation Kit	QA-6BRAA-GZ

Compaq welcomes your comments and suggestions on this manual. Your input will help us to write documentation that meets your needs. Please send your suggestions using one of the following methods:

- This postage-paid form
- Internet electronic mail: readers_comment@zk3.dec.com
- Fax: (603) 884-0120, Attn: UBPG Publications, ZKO3-3/Y32

If you are not using this form, please be sure you include the name of the document, the page number, and the product name and version.

Please rate this manual:

	Excellent	Good	Fair	Poor
Accuracy (software works as manual says)	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Clarity (easy to understand)	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Organization (structure of subject matter)	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Figures (useful)	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Examples (useful)	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Index (ability to find topic)	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Usability (ability to access information quickly)	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

Please list errors you have found in this manual:

Page	Description
_____	_____
_____	_____
